You can prove this by one ride. The Super-Six feats will amaze you. You never saw such effortless performance, such flexibility, such quick response.

No man can doubt that the Super-Six is the greatest motor built. And the luxurious bodies on this new Hudson make the car look its supremacy.

A BASIC PATENT

Note that the Super-Six is controlled by a basic patent. There is nothing else like it. Any man who wants this reserve power, this smoothness, this endurance, must buy a Hudson to get them.

And men will want them. If you don't think so, try a ride in the Super-Six.

The Automobile

Toledo—Second Automobile City

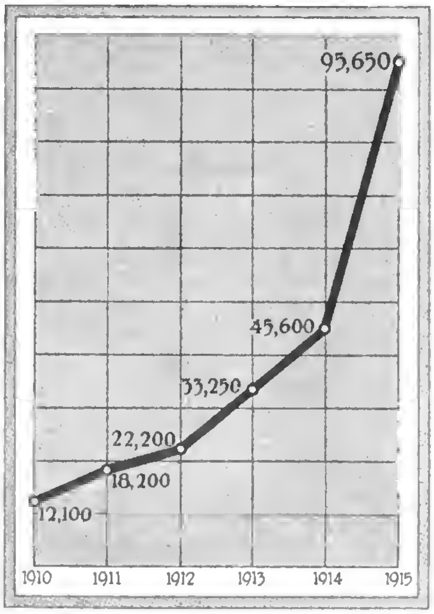
95,650 Cars Left Its Factories in 1915—1000 Electric Systems and 25,000 Spark Plugs Per Day

By L. V. Spencer

TOLEDO is the second automobile city in America. It acknowledges premier position to Detroit, first automobile city of the world. Toledo's rank as second city in automobiledom, to-day the fourth industry in the country, is unique in divers respects. Toledo owes its present automobile status to one manufacturer. Detroit's greatness is in the number and variety of its automobile factories, but Toledo's is in the immensity and concentration of the few. Toledo rose to second place in the last six years; Detroit has held its leadership for more than double that time.

A Rapid Rise

In six brief years Toledo has risen from semi-obscurity as an automobile city until to-day when one-third of its entire army of 75,000 workers is engaged in building automobiles, automobile components and automobile accessories. To-day one-fifth of Toledo's entire army of wage earners is employed by the vast Willys-Overland organization, operating the largest individual automobile factory in the world and occupying second position as the world's greatest producer of automobiles.



Toledo's automobile production since 1910. Note the sharp upward trend in 1915. This is chiefly owing to the expansion of the Overland output

Official figures establish Toledo's rank in second place as an automobile city. In 1915 there were 95,650 automobiles built within its boundaries. Toledo has thirty-five factories connected with the automobile industry, their payrolls constituting a large percentage of the $52,000,000 paid to Toledo wage earners and salaried employees in 1915, although thirty-six new manufacturing institutions of different lines came to the city during the year to help swell the wage and salary total. During 1914, which was somewhat of a time of depression, eighteen plants started operations, whereas in 1913 there were twenty-five.

Population Gains 75,748

Since the automobile industry began to exert its influence on Toledo in 1910 the population of the city has jumped from 168,497 to 244,245, a gain of 75,748.

Bird's-eye view of the great Willys-Overland factories. From a plant of only 300,000 sq. ft. floor area, employing 250 men, in 1908, this 103 acres, employing 15,000 men and building 1000 cars a day

On this basis the growth by 1920 will be about four times what it was for the period from 1900 to 1910 which was 36,675, or from 131,822 to 168,497. In other words, Toledo's population in 1920 may be 390,945. The automobile industry and the business that is allied with it have contributed more than any other single factor to this remarkable growth in population, while Toledo's wealth as well as its population have increased in the past six years far more than they did in any previous period of twice that length.

The increase in the value of the products of Toledo factories almost doubled in the period from 1913 to 1915 as indicated in the tabulation on this page. This increase is largely due to the progress of the automobile and its allied industries although other lines of business in the city have enjoyed somewhat similar growth. The value of Toledo-manufactured products in 1909 was $61,230,000, this practically doubling in 1913, attaining a total of $111,599,000, while the magnitude of increase is shown by the 1915 total of $210,000,000 the value having nearly doubled in the two years' period.

Bank clearings have increased consistently from $186,169,000 in 1908 to $331,579,324 in 1915; while the cost of building construction in the city gained steadily each year over $1,000,000, varying from $2,092,873 in 1908 to $7,622,244 in 1915.

95,650 Cars in 1915

Toledo's increase of production of automobiles has been steady, the ratio of gain rising each year. In 1910 its contribution to the industry was 12,100 cars, increasing to 18,200 in 1911, then to 22,200 in 1912; in 1913 its factories produced 33,250 which was increased to 45,600 in 1914. In 1915, however, the biggest gain took place, the total output being 95,650 or a gain of over 100 per cent as compared with the 1914 figure. For 1916 a production of over 150,000 automobiles is predicted.

Excellent Shipping Facilities

The advantageous position attained by Toledo in an industry that ranks fourth in the United States to-day is not due to any over-night growth, but to steady and solid expansion of its motor car and parts factories that have thrived on the most advantageous kind of manufacturing conditions. Toledo's favorable location as a shipping point, its close proximity to a majority of the markets of the country and the co-operative boosting spirit of its people are factors that are drawing the attention of automobile business men and attracting new industries continually.

Big Accessory Production

There might have been a time several years ago when other motor car producing centers could dispute Toledo's claim to second position, but now the Ohio city has so far outdistanced its nearest rival that such rivalry is a thing of the past. No one now thinks of any automobile city in the world as a sort of understudy to Detroit except Toledo, which during 1915 contributed 95,650 machines to an eager public. Nor is this all. One thousand starting and lighting systems, 25,000 spark plugs and many other parts and accessories were made each day during 1915 by specialists in their lines whose businesses have grown to enormous proportions. Even now these big accessory producers have practically doubled these daily figures of a year ago.

So far as its automobile industry is concerned, at least, Toledo impresses you the same as Detroit. You see enormous factories that only half a dozen years ago were scarcely in

1915	7,622,244

organization has grown until it occupies factory buildings aggregating

business at all. You see on all sides evidences of a marvelous growth that is so busy taking care of its very bigness that it has not the time to stop and tell you how it was done. Toledo does not care much about the past; does not deal in post mortems, but is looking ever ahead and striving to keep pace with the prosperity and progress that are coming to it in ever-increasing quantities.

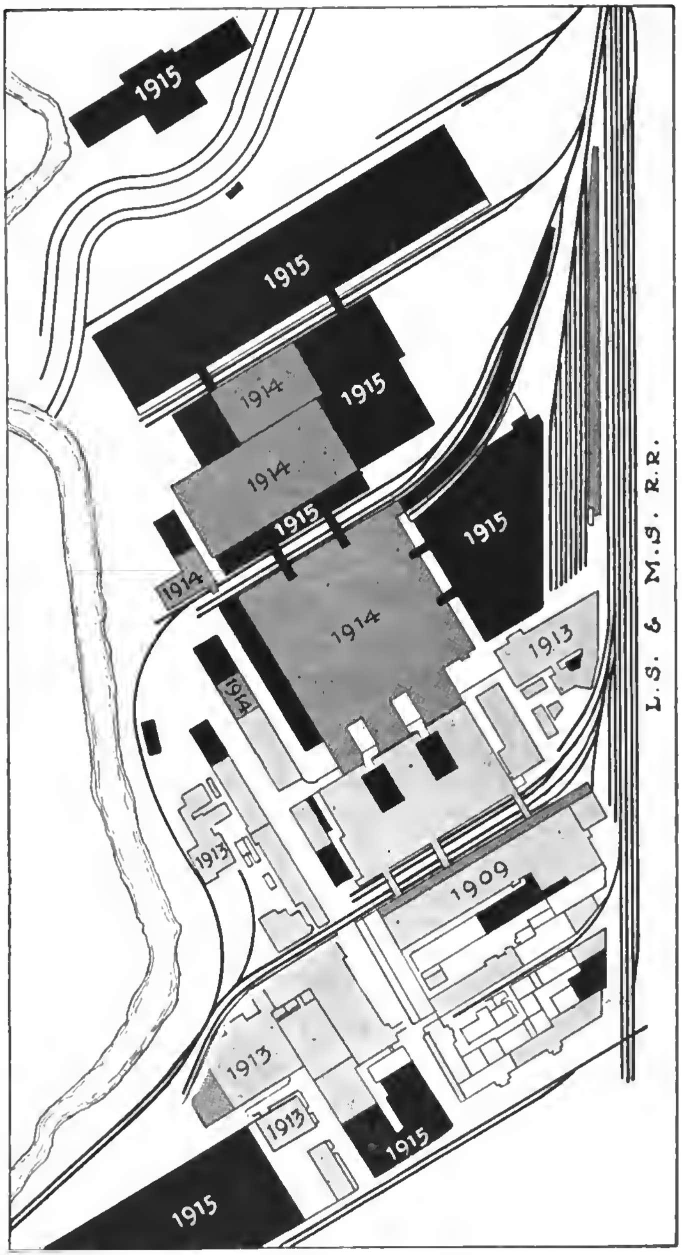
Overland's Phenomenal Rise

From these statistics it will be seen that it was a most fortunate day for Toledo when John N. Willys, wizard of finance and automobile, took serious notice of the thriving Ohio center. It was in 1909 that he purchased the old Pope-Toledo plant and used it as a nucleus around which was destined to be developed the largest single automobile manufacturing institution in the world.

The history of the Overland automobile is like a tale from the Arabian Nights, the only difference being that it is a true story. The name Overland was first applied to an automobile in the fall of 1902, at which time the Standard Wheel Co., Terre Haute, Ind., completed the design of and built a 3½-hp. runabout. A number of these were sold, perhaps a dozen. The following year, the concern succeeded in building and selling seventy-five cars—a large output for that year. But matters did not go very well, and in 1907 the sales of Overland cars, then made in Indianapolis, did not exceed forty. But in January, 1908, Mr. Willys acquired control and took the presidency and the company name was changed to the Willys-Overland Co. This was the beginning of the present great business, and under the able direction of its head the whole administration was reorganized, the first year's business under the new management totaling 465 cars.

1000 Cars a Day

Looking about for a new factory site, Mr. Willys saw the possibilities of Toledo and of the few Pope-Toledo buildings scattered over a 7-acre lot. When he took it over this plant boasted of 300,000 sq. ft. of floorspace and employed 250 men, a factory of no mean size, by the way. Each year since then has seen new buildings spring up in the Overland group until now they have an aggregate floor area of 103 acres, house 15,000 employees and possess a production capacity of 1000 cars a day. Undoubtedly this output will be attained during the present year, for even now the average daily schedule is 700 cars, the record being 722 cars in 24 hr. Some definite idea of the strides which this great factory has made may be gathered from the following:



Diagrammatic view of Willys-Overland plants, showing the yearly additions and the excellent railroad facilities

OUTPUT BY CALENDAR YEARS—OVERLAND CARS

Year	Cars
1907	40
1908	465
1909	4,000
1910	12,000
1911	18,000
1912	22,000
1913	33,000
1914	45,000
1915	94,437
1916 (planned)	150,000

The diagrammatic map of the Overland factory will perhaps best illustrate how the expansion has been kept up steadily to meet the increasing demand for cars. The greatest single year's increase was during the last twelve months, when 1,765,840 sq. ft. were added.

Naturally such an enormous industrial organization has a big influence upon Toledo, employing as Overland does at the present time one-fifth of the total working population of the city. It has not only been a big factor in the rapid advancement of the population, but it has logically served to attract other factories making parts and accessories, and has served to show what the latent possibiilties of the city as a manufacturing center are.

The result has been a gradual increase in the number of establishments dependent either wholly or in part upon the automobile trade, for they know that here they can get experienced automobile labor, can secure co-operation from others in the industry and can have adequate shipping facilities. The same economic reasons are back of the growth of Toledo as an automobile center as are back of the concentration of the rubber goods and tire-making industry at Akron, and the centering of the iron and steel industry at Pittsburgh.

Thirty-five plants are now operating in Toledo that are allied with the automobile. Not all of them are to be regarded as exclusively motor vehicle or parts factories, but a majority are dependent upon the automobile business entirely. In them are working approximately 24,000 persons—one-third of the whole working class of the city. Is it any wonder the industry has meant much to Toledo?

50,000 Spark Plugs Daily

There is, for example, the Champion Spark Plug Co., which has made a striking success of concentration upon one thing alone—the spark plug. The daily output now ranges from 40,000 to 45,000 plugs requiring 300 persons with the aid of the most modern kinds of special machinery to do it. Beginning in a minute plant in May, 1910, with twenty-five employees and pushed to its utmost to make 2000 plugs a week, this concentrated organization has now outgrown a modern four-story factory building and is erecting a six-story addition as well as adding two stories to its main plant, so that, when completed 55,000 sq. ft. will be provided.

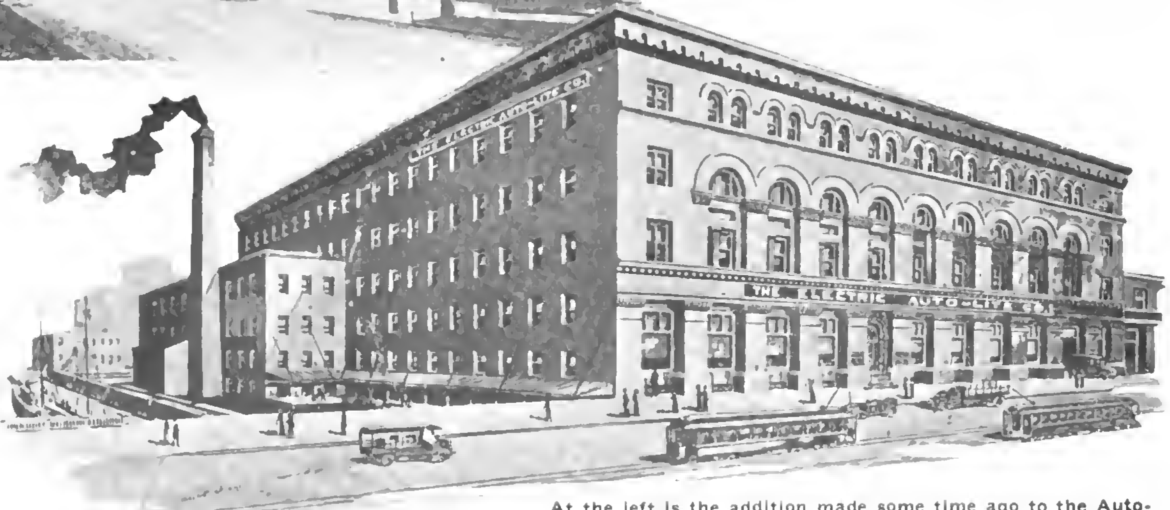
Toledo has two other big makers of motor vehicles. These are Milburn and Ohio concerns, both of which build electric cars. The Ohio Electric Car Co. began in 1910, and strangely enough, occupied at the start a part of the factory of the Milburn Wagon Co., which has long been one of Toledo's big industries. That first year Ohio succeeded in building twelve cars and had ten men on its payroll. In 1912 the present large plant was built which has a three-story main building 60 by 340. Later other buildings were added, each two stories high, one measuring 60 by 240 ft. and the other 80 by 160. The factory has a yearly output of 600 vehicles, and employs 250 men.

The Milburn Wagon Co. launched into the electric automobile business December, 1914, and during last year turned out 600 cars. These are of the light type and have struck out in a new direction so far as electric design is concerned. This year, the Milburn production plans call for 1200 cars, and judging from the business reported for January and the month previous, this figure will be readily attained. Although Milburn makes wagons as well as electric cars, the addition of the motor vehicle has meant an increase in the payroll from 400 to 800 men, and at present they are working 14 hr. a day.

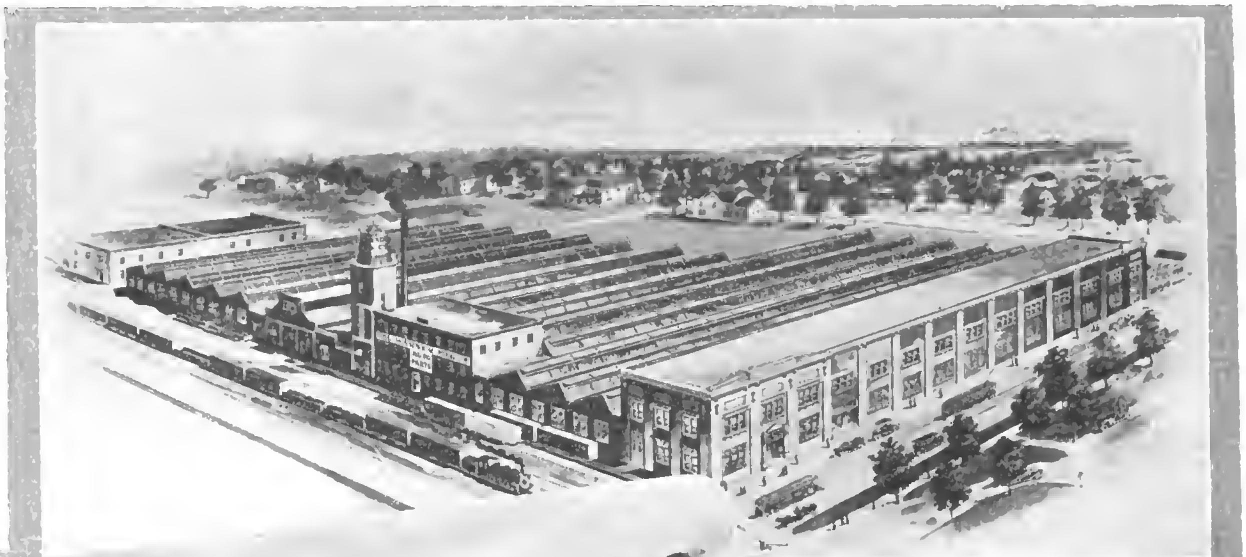
2500 Electric Systems a Day

Concentration has also played an important part in the wonderful growth of the Electric Auto-Lite Co., which now has a daily output of 2500 complete electric starting and lighting systems. Close to the Overland plant, one of its main users, this factory has grown from an original production of ten lighting generators a day, at that time no starting units being built. Fifteen men drew their pay from Auto-Lite then. Production was stepped up to twenty-five generators early in 1912, then to fifty generators and fifty starters in 1913. But the original plant was soon outgrown and in 1914 Auto-Lite moved to larger quarters, with the result that in 1914 the daily output was 350 complete systems with 700 employees. Before the end of 1914 production had jumped to 600 a day, and in June, 1915, when the big plant of 150,000 sq. ft. formerly occupied by the General Electric Co., was added, output took another boost to 800 a day and 1300 persons were employed. Last fall production was again increased to 1000 sets daily, requiring the services of 2100 persons. Since then a new factory building has been completed which makes possible the present enormous output, 2500. The new building is 105 by 380 ft. and four stories, swelling the Auto-Lite concern's space to over 400,000 sq. ft.

Another of Toledo's big automobile concerns is the Warner Mfg. Co. which does a big parts business, such as gearsets and similar components. Since its



At the left is the addition made some time ago to the Auto-Lite plant, illustrated below, more than doubling its facilities



Upper—Plant of the Warner Mfg. Co. This company is a large producer of gearsets and similar components. Its working force is now 600 to 700 men

Middle—Plant of the Champion Spark Plug Co., an organization which has grown from a small establishment, employing twenty-five persons in 1910, with a weekly output of 2000 plugs, to a large plant with 300 employees, turning out from 40,000 to 45,000 plugs per day

Below—Factory of the Ohio Electric Car Co., which manufactures 600 electric cars per year and gives employment to 250 men

inception seven years ago this factory has enjoyed a 75 per cent business increase. The start was made with 200 men, but now it employs 600 to 700.

As an example of intelligent management, and good product in combination with Toledo's facilities for the manufacturer, the case of the McNaull Tire Co. can be cited. Starting not over one year ago, this concern is now located in a 50 by 220 factory with a capacity of 100 tires a day and employs seventy men.

Others that are growing rapidly and which have wisely chosen Toledo in which to cast their lot are the Bock Bearing Co.; Dewey, Anderson Mfg. Co.; Mather Spring Co.; Bunting Brass & Bronze Co.; Doehler Die-Casting Co.; Miller Storage Battery Co.; Seiss Mfg. Co.; Gendron Wheel Co., etc.

From these superficial glimpses of some of the thriving plants that have helped to make Toledo's name known wherever automobiles are sold, it is at once evident that they have played a big part in the making of the city. Yet while this is undoubtedly true to a very large extent, the fact must not be overlooked that Toledo also made them, in a sense. The city offers them its excellent manufacturing advantages, and the factories repay it for what it gives by helping to add to the corporate wealth, to the prestige and to the size of the community.

Big Center of Population

For Toledo is really most advantageously placed on the map of the United States. To realize this examine its strategic manufacturing position. Located at the western end of Lake Erie where the big lake freighters can reach it with no trouble at all, and offering a good terminal point for the meeting of rail and lake lines, it is actually the peer of almost any city of the country in this respect. Half the population of the United States is within a radius of 500 miles, and it is perhaps this fact as much as anything else that has attracted manufacturers.

But this great central location could be discounted somewhat were it not that Toledo is blessed with twenty-three steam and electric railroad lines, tapping nearly every section of the country. A salient point about the entire railroad situation is the terminal belt railroad that extends entirely around the city and has direct track connections with all roads that enter. The advantage of this for quick transfer of shipments from any spur track to any main line is apparent.

Five Steamship Lines

But in addition to this remarkable array of railroads, Toledo also is fortunate in being the terminus of five regular steamship lines of the Great Lakes, besides having a dozen interurban trolley lines whose main business is passenger traffic.

As a further indication of Toledo's industrial position, the

Where Toledo's land and water shipping meet. The New York Central freight house, with a view of some of the wharves

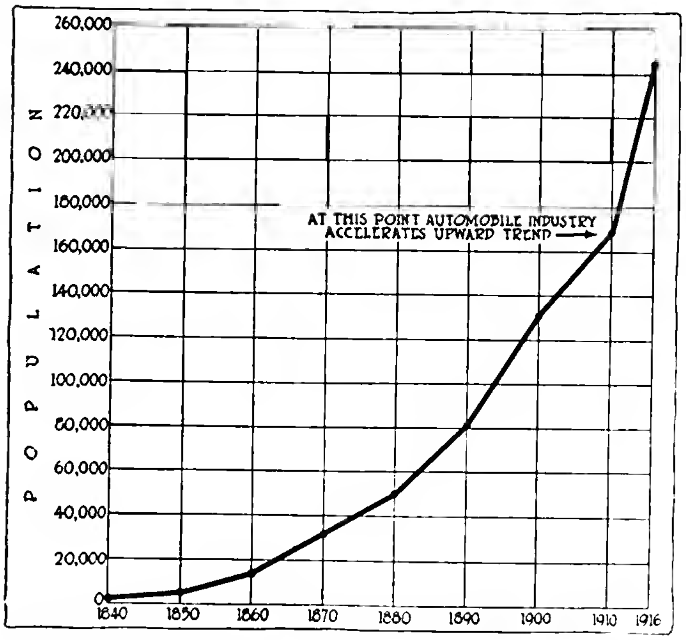
harbor is of special interest. A natural haven, it has been made of immense commercial value by extensive improvements so that the straight channel now is 21 ft. deep and 400 ft. wide, sufficient for the largest freighter. Being the connecting link between lake and rail, the city has received a wonderful coal-and-iron-ore-carrying trade, as well as an enormous grain jobbing business, which during last year swelled to a value of $90,000,000.

These facts are cited to show why the city has been picked as a logical location for centralization of automobile production. The railroads have been quick to realize the strategic position of the city, and they have built adequate dock and terminal facilities, some of them combining their land freight sheds with their lake dockage facilities.

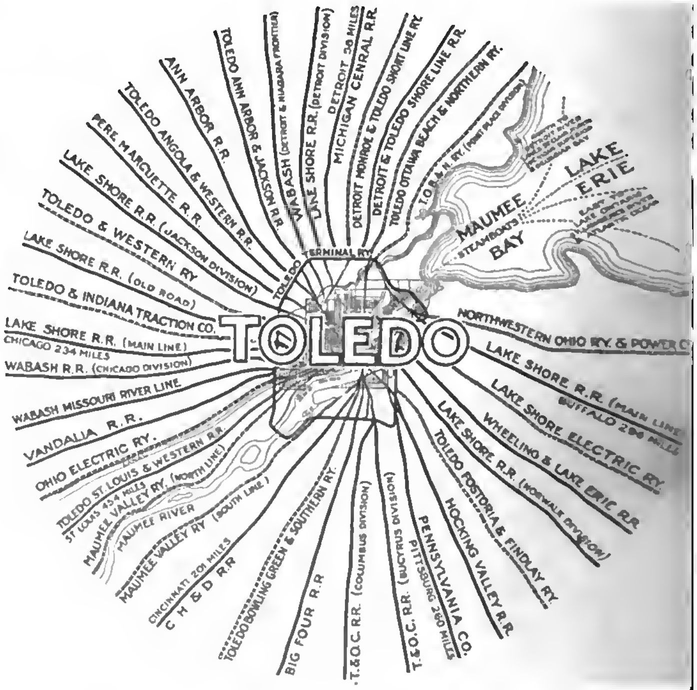
As a retail center, particularly for the sale of automobiles, Toledo is well situated. The same shipping facilities, commercial advantages and wealth that make it an ideal manufacturing community, work to the distinct advantage of the dealer or distributor of cars. That Toledo is a logical center for the distribution over a wide territory is proved by the fact that some of the largest automobile builders have allotted big areas to their distributors here. The five largest distributors alone have contracted for 15,850 cars to sell in their Ohio territories in and around Toledo during 1916. The largest distributor in the city, for instance, who handles a popular-priced car, has a territory covering all of Ohio with the exception of Cleveland, and including West Virginia, Kentucky, four counties in Michigan, nine in Indiana and eight in Virginia. Thus, so advantageous does his factory, which is in another city, consider Toledo as a distributing point that it has allowed him an enormous field radiating from it. This distributor, by the way, has contracted for 5000 cars this year.

Further Facts Are Needless

It is needless to go further with facts and figures to show the great advantage of Toledo as a commercial center. It speaks much for the farsightedness and business acumen of men in the automobile industry that they have picked out a city which is destined to play so important a part in the industrial history of our country, and these will help Toledo as Toledo helps them, for as the city grows so shall develop the men who are a part of it.



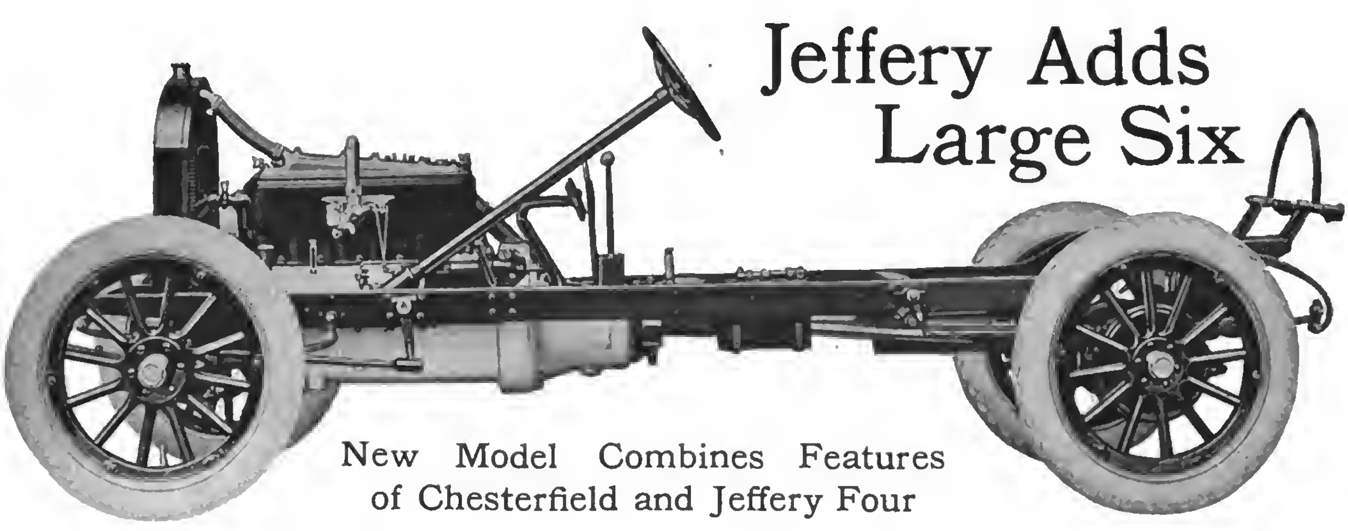
Illustrating Toledo's increase in population since 1840. Note the recent rapid growth, largely due to the automobile industry



Toledo is the terminus of twenty-three steam, twelve electric rail road lines and five steamship lines

Jeffery Adds Large Six

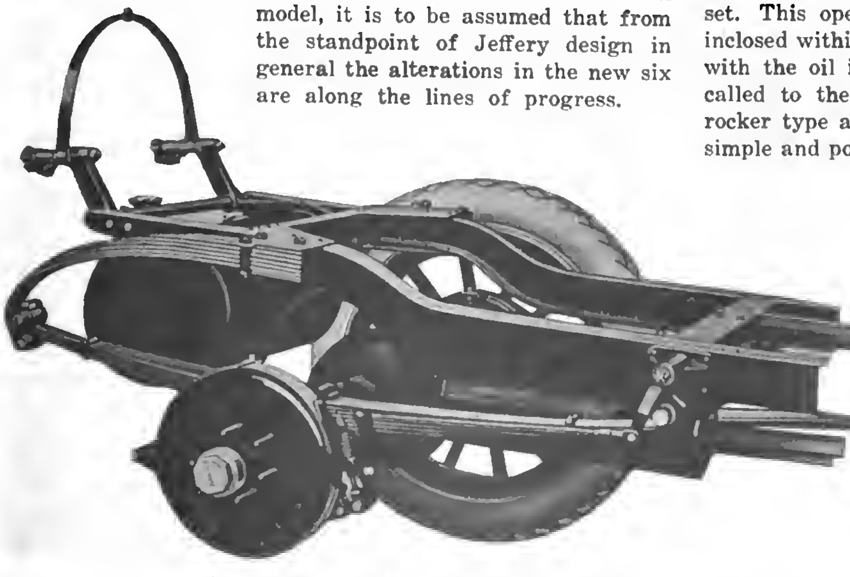
New Model Combines Features of Chesterfield and Jeffery Four



THE Thomas B. Jeffery Co., Kenosha, Wis., has just begun delivery of a new six-cylinder car, model 661. This is more modern in design and larger in size than the Jeffery Chesterfield, the previous six, and with the Jeffrey four, which has been on the market for some time, will comprise the chief unit in the Jeffery passenger car program.

The new six to be marketed as a seven-passenger tourist at $1,450 is externally a very up-to-date car, having a much more pronounced roll inward to the sides than has been characteristic of previous Jeffery designs, and with a straight line from radiator to windshield and smooth hood and cowl becomes the very latest exemplification of the marine motif in motor car superstructure. The radiator is narrow and unusually high, so that it is possible to combine the modish horizontal hood line with a downward sweep to the roll edge of the passenger compartments and at the same time provide a very roomy car. With the wheelbase of 120 in. a very roomy tonneau is provided and one which is uncluttered by spare seats, for when the latter are not in use they fold forward into the backs of the forward seats. The latter are divided, giving the vestibule type of seating arrangement, which permits unimpeded communication between forward and rear compartments.

As compared with the previous six, the new car incorporates a number of changes mechanically. In most of these a design which has been found to work out well with the four has been followed, rather than that incorporated in the Chesterfield six, and as the four is a much more modern model, it is to be assumed that from the standpoint of Jeffery design in general the alterations in the new six are along the lines of progress.



Hotchkiss drive used with three-quarter spring

There is an increase in motor dimensions to 3½ by 5¼ in., which is ½ in. greater bore and a ¼ in. longer stroke than possessed by the former six and gives a piston displacement of 333 cu. in., which is 50 per cent greater than that of the former six.

The new six, too, marks the complete conversion of the Jeffery passenger cars to spiral bevel drive, a design employed in the four and a departure from the practice in former six which included a worm drive in its specifications. Likewise cantilever springing which was a feature of the earlier six-cylinder car has given way to three-quarter elliptic rear suspension. In this respect the new six is similar to the four.

Braking incorporates a design which has proved successful in the four-cylinder car, namely, that is the location of the emergency brake on a drum at the rear of the gearset operating directly on the drive shaft. This gives a very direct and positive application of the emergency brake through short linkages and goes very far toward making an exceptionally clean looking chassis. With the connections to the service brakes carried outside of the frame and springs where they are accessible for adjustment and oiling, there is nothing left within the rear of the exceedingly clean frame except the propeller shaft.

A feature is the very neat arrangement of the drive to the Van Sicklen speedometer. Instead of the two pulleys and belt from the driveshaft previously used, a special gear is provided which meshes with the secondary gear in the gearset. This operates the speedometer drive and is completely inclosed within the gearbox where it is supplied automatically with the oil in the latter. Special attention, too, should be called to the unusually neat accelerator pedal which is a rocker type and provides not only easy foot action, but very simple and positive connection with the throttle.

Details of Engine

To take up the design of the car in detail: The block cast, L-head, motor has both the upper and lower halves of the horizontally split crankcase made of aluminum. The valves and consequently the camshaft are on the right side and the lay shaft, which drives in succession the water pump, air pump, generator and magneto, is utilized along every inch of its length but without such crowding as to make any of the accessories inaccessible.

The pistons are iron 5½ in. in length with pins 1 5/64 in. in diameter; eccentric piston rings are used. Connecting rods are forgings 11¼ in. long, their caps being fastened by

Jeffery Big Six

two chrome nickel steel bulbs. Phosphor bronze piston pin bearings are located within the piston. The crankshaft is 35 to 25 carbon steel and turns on four die-cast babbitt bearings, the two center ones being 2 by 2¼ in. The front 1¾ by 2⅞ and the rear 2⅛ by 3¼ in. The valves have a lift of 5/16 in. in the clear, both being 1 11/16 in. in diameter and made of tungsten steel. The camshaft is a forging with the cams intregral and tappets of mushroom type.

The valve timing of the motor is as follows:

Inlet opens 5 deg. late.
Inlet closes 45 deg. late.
Exhaust closes 5 deg. late.
Exhaust opens 55 deg. early.

The timing gears are helical with a 26-deg. helix and a 10 pitch. The gears all 1⅛ in. across the face, which should be sufficient to give long life before backlash or wear develops. The motor complete with its control parts, complete with fan, carbureter, magneto, starter and generator weighs 700 lb. according to factory specifications. The firing order of the engine is 1, 5, 3, 6, 2, 4, and ignition is cared for by a Dixie magneto.

Lubrication is a circulating system maintained by a gear pump, from an oil reservoir which is located beneath the crankcase and forced through a pipe to the top of the main bearings. From the main bearings, the oil overflows into the bottom of the crankcase into which the connecting rods dip. These pockets have overflow holes in one side which allow the oil to drain back into the reservoir beneath, so that a constant level of oil is maintained. An indicator which shows at all times the level of the oil in the reservoir is placed beside the combination breather and filling tube. The oil pump and strainer are removable from the bottom of the crankcase for cleaning without disturbing the other parts. A separate lead to the timing gears provides a constant stream of oil from the pump for these. The circulation of cooling water is by means of a pump on the lay shaft and a two-bladed aeroplane propeller type of fan is employed.

Vacuum Fuel Feed Used

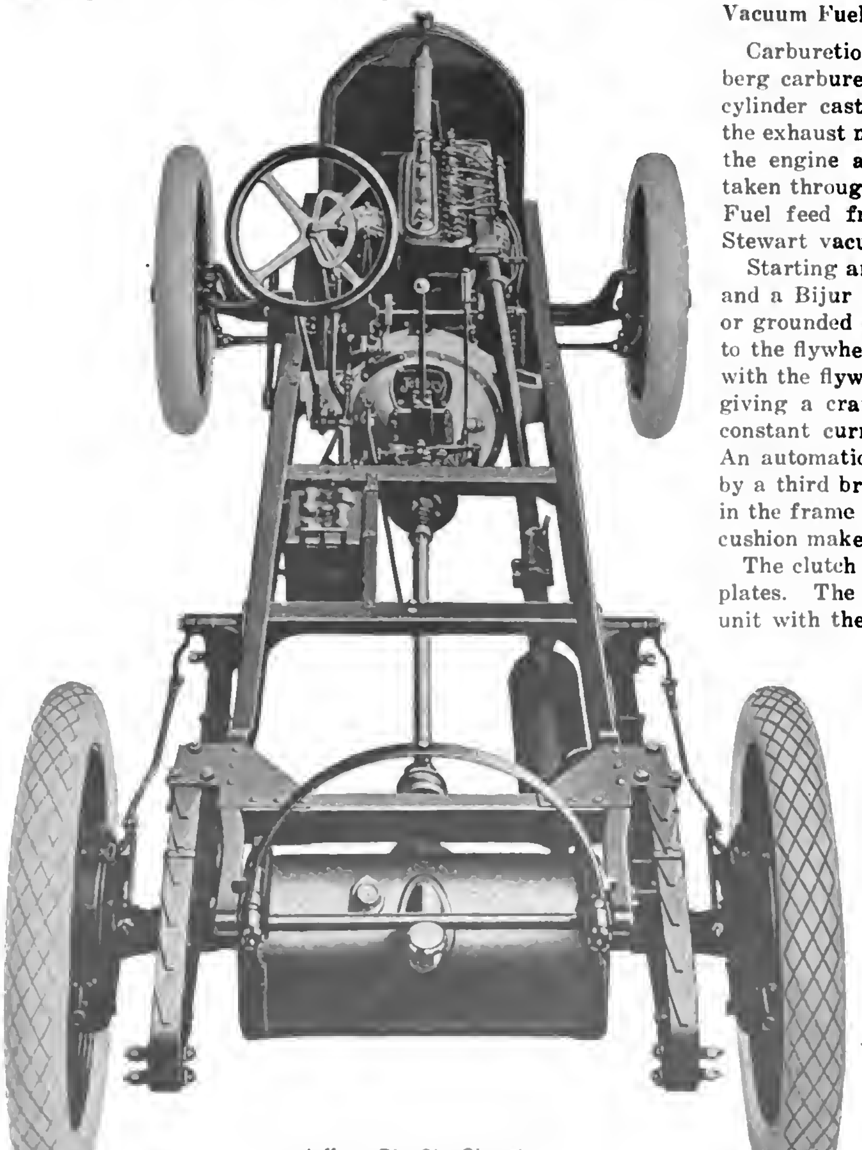
Carburetion is by means of the new model L. B. Stromberg carbureter of the horizontal type bolted directly to the cylinder casting and heated by hot air drawn from around the exhaust manifold. As the exhaust header is on one side of the engine and the carbureter on the other, the hot air is taken through a pipe which goes over the top of the cylinder. Fuel feed from the rear tank is supplied by means of a Stewart vacuum gravity system.

Starting and lighting is taken care of by a Bijur generator and a Bijur motor, which are separate units. A single wire or grounded system is used and the starting motor is geared to the flywheel by a sliding pinion which is shifted into mesh with the flywheel teeth when the starting switch is depressed, giving a cranking speed of 165 r.p.m. The generator is a constant current type with a maximum output of 12 amp. An automatic switch located inside the generator is operated by a third brush. The battery is mounted in a special cradle in the frame in such position that removal of the driver's seat cushion makes it accessible for filling. It is a 6-80 U.S.L.

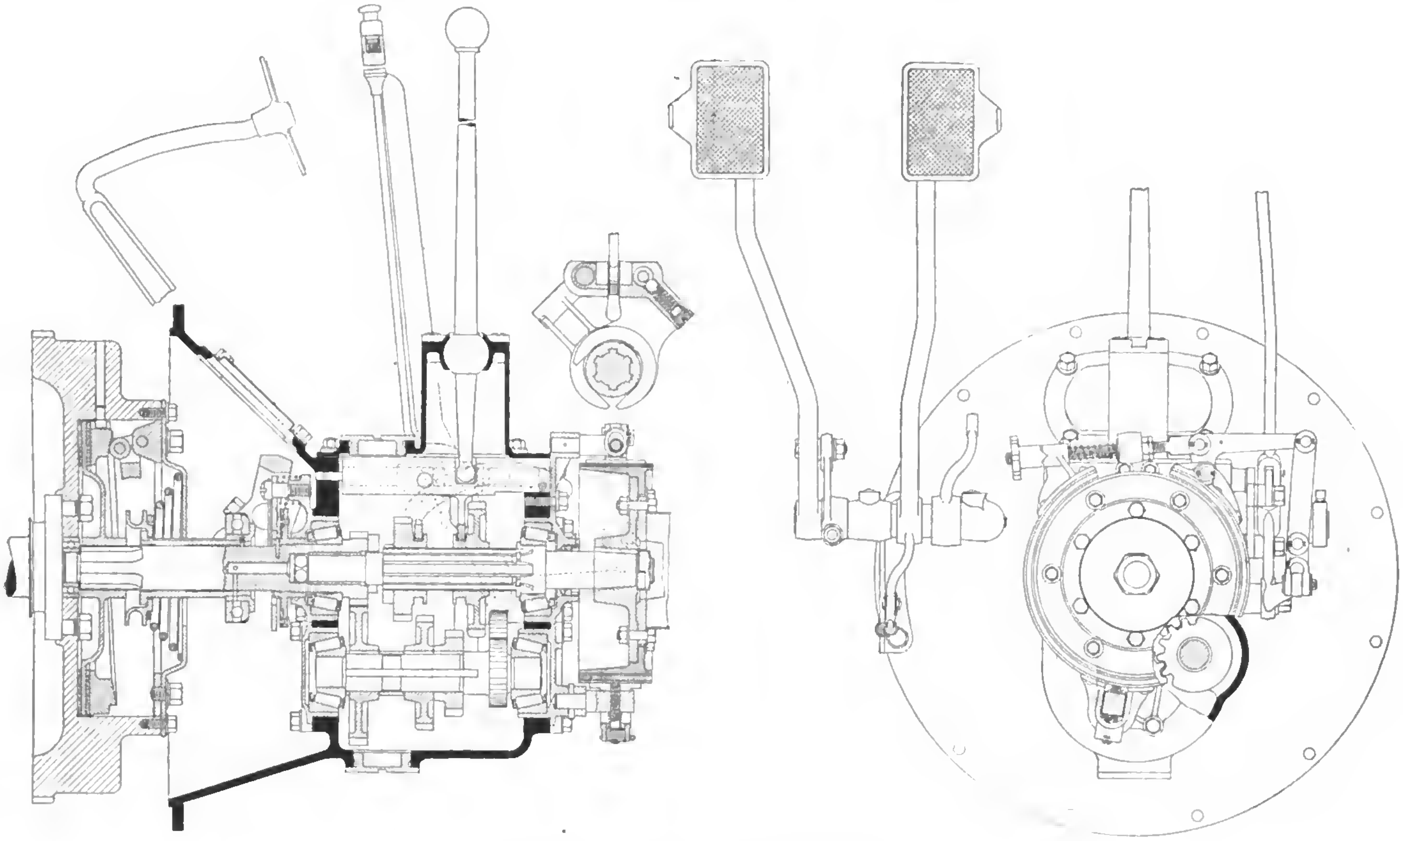
The clutch is a three-plate type, one steel and two asbestos plates. The gearset gives three speeds forward and is in unit with the motor, the whole power plant being suspended on three points. The gears have a ⅝-in. face and the shafts are mounted on taper roller bearings.

The rear axle is semi-floating, having a malleable iron center with alloy steel tubular ends. With this construction it is not necessary to use a truss rod. Removal of a large cover over the differential housing makes the differential readily removable and accessible for adjustment. The pinion and large driven gear are provided with adjustments for taking up wear.

The frame is pressed steel and provided with four cross members which make it very rigid. The side rails are extended to the rear to provide a support for the gasoline tank and a spare tire. The spare tire carrier is a semicircle instead of the usual complete circle and is held by two quick operated hand locks, one at either end of the horizontal diameter of the tire carrier.



Jeffery Big Six Chassis



Details of Gearset and Transmission Brake

Provision for locking the spare tire with a padlock is made, a detail likely to be much appreciated.

Tires are 35 by 4½ straight side on Stanwell demountable rims. The equipment is all that is to be expected of a car of this size and includes the electric lighting instrument board on which are located the Van Sicklen speedometer, electric generator indicator, oil sight feed gage, ignition and lighting switches and fuse box. Double bulb head lamps are mounted directly on the front frame with the wiring carried through the lamp standards.

Another convenient detail is that the ignition switch is operated by a key in the center of the lighting switch and can be locked in any position. All the electric wiring is carried in conduits. The horn is a Hartford Machine Screw Co. product.

As to the actual performance of the car, factory tests have shown that the engine develops 53 hp. at a speed of 2000 r.p.m., although according to the N. A. C. C. formula it is rated at 29.4 hp. at 1000 feet per minute piston speed. Factory tests have shown a speed of 55 m.p.h. with a high gear low limit of 3 m.p.h. Gasoline mileage is given at 15 to 16 and oil 300 to 400 per gallon.

McKeen Highway Coach

The illustration at the bottom of this page shows a type of vehicle put into service some eight months ago. The makers are well-known for their gasoline railroad cars which are similar in appearance, though, of course, somewhat larger than the road automobile car.

Left—McKeen-United Highway Coach. A luxurious chair car on a 3½-ton chassis, intended for interurban transportation. Right—Chair used in Highway Coach. Observe the very long coil spring which supports the weight

Determining Frame Sections

Automobile Frame Section Modulus and Section Characteristics

By A. L. Nelson

THE need of a frame section modulus table for the study of section characteristics is becoming more and more urgent as engineers progress in placing frame design on a rational basis in co-relation with actual road service tests of frames. The purpose of this article is to present a reliable section modulus table covering ⅛, 5/32 and 3/16-in. stock in all sizes of sections likely to be used in pleasure cars; also to call attention to the study of frame section characteristics for comparative analysis. It seems necessary to mention some of the general methods of design, but details of the design are aside from the purpose of this article, so consequently they will not be given.

General Considerations in Design

In designing a frame the bending moments at the most important sections, particularly around the location of the axle center lines where the depth of the sections are decreased for spring clearance, must be determined, and the frame sections designed to resist the corresponding moments. Just what gage of frame stock, depth and width of section is best at each point is a problem well worth considering carefully. A table of section modulus is an important item in aiding the engineer in selecting proper frame section dimensions to resist a given moment for a given stress. (Section modulus equals the bending moment in lb.-in. divided by the allowable stress in lb. per square inch.)

However, a frame section is called upon to withstand a wide range of conditions practically undeterminable in a direct way. To overcome this difficulty a standard of analysis is selected which will give conditions easily analyzed and, at the same time, will be closely proportional to the average actual conditions met in road service. The proportionality factor may then be determined from analysis of frames giving satisfactory service, together with the aid of general engineering experiences. The allowable unit working stress of the frame material is directly related to its physical properties and to the characteristics of the size of sections, thickness of stock used, etc., as will be pointed out later.

Standard Conditions of Analysis

For comparative analysis the loading of the frame may be taken as that resulting from the car with normal passenger load, under static conditions. For instance, such loads as the radiator, motor at supports, transmission, gasoline and tank, body weight at points of support, etc., can be closely approximated and considered as concentrated loads. Furthermore, since the interval of spacing of these loads is somewhat uniformly distributed the miscellaneous loads as fenders, etc., can be distributed with the above principal loads. Having the loading of the frame established, the reactions of the chassis spring and the bending moments at each load may be determined analytically or graphically by standard methods.

Frame-Section Characteristics

As has already been mentioned, the allowable working stress should not be based alone on the physical properties of the material used, but also on the thickness of stock and general characteristics of the sections. Surface defects in ⅛-in. stock bear a larger ratio to the nominal thickness than they do to 5/32 or 3/16-in. stock. Furthermore, the thickness of stock has an important bearing on how much reliance may be placed on the theoretical section modulus. Obviously, for an extra thin stock and a large section the complex stresses set up by simple bending could not even be estimated; hence care must be used in making allowance for complex stresses not accounted for by the methods of computation that are in general use in engineering. It is for such reasons as the above that stresses for ⅛-in. stock used in large sections should be chosen lower than the stresses allowable in heavier stock.

Although the heavier stock makes the more stable section in resisting complex stresses, it does not follow necessarily that it is the most desirable, for the weight per unit length of section may be very great compared with the strength. The thinner stock for the same weight per unit length has its metal placed more effectively to resist bending—that is, the section may be made of more liberal depth and width for the same weight. However, a part of this gain is sacrificed to the lower stresses imposed by the thinner stock. The theoretical gain from using the thinner stock, as for instance ⅛-in., is best studied by graphical comparisons with the heavier stocks, a few of which will now be presented for particular cases.

Effectiveness of Metal Distribution

The effectiveness of metal distribution may be taken as the ratio of the section modulus to the area of the section. Figs. 1 and 2 were constructed for illustrating this property in a comparative way. In Fig. 1, 6-in. depth of section of various widths is compared with 4-in. depth of section, ⅛-in. stock. Curves No. 1 and 2 were plotted by taking values of the section modulus from the frame table for a few widths, and dividing by the corresponding areas of the sections. These ratios were plotted as ordinates and the frame widths as abscissa. Then the smooth curves were drawn through the plotted points. Curve No. 3 gives the results represented in per cent gain in effectiveness of metal distribution of the 6-in. depth of section over the 4-in. for various widths. With widths as used in practice, say above 1½ in. the per cent gain increases with the width of section. The mean gain in this particular camparison is about 38 per cent, a very material increase in effectiveness of metal distribution in favor of the deep sections.

Most of our current frames have comparatively shallow sections, excepting those of some of the cars of recent design. To account for shallow sections, it seems that the designers have been seeking for "looks" rather than actually seeking for the best utilization of metal distribution. Designers trying to use ⅛-in. stock without adopting deeper sections are expecting more than can possibly be realized. As has before been pointed out the ⅛-in. stock should be stressed lower than 5/32 or 3/16-in. stock. This can be done by increasing the section depth of the ⅛-in. stock and still gain in the lightness of construction due to the better distribution of metal. The lower stresses are also advantageous in that the accompanying deflection of the frame is less. The latter necessitates less camber of the frame to take care of the initial deflection;

also lessens body door troubles caused by excessive frame deflections.

Returning to the figures: Fig. 2 is the same as Fig. 1, except variable depths of sections of 1 and 3-in. (⅛-in. stock) were selected. The 3-in. width shows a gain of 26 to 35 per cent over that of 1-in., increasing with the depth of section. Effectiveness of metal distribution is shown by Figs. 1 and 2 to increase both with the depth and with the width of section.

Weight per Unit Length and Strength Comparison

In order to compare the weight per unit length with the strength of section, the section moduli of various sections are plotted as abscissa with their corresponding areas as ordinates. The area is chosen for convenience, since it is proportional to the weight per unit length. Figs. 3 and 4 are given for this comparison.

Fig. 3 is for constant width of sections (2-in.) of ⅛, 5/32 and 3/16-in. stock. The curves were plotted by choosing section moduli at random, then referring these to the section modulus table to obtain the size of the sections and then their corresponding areas were computed. Curve No. 4, Fig. 3, gives the results in per cent increase, 14 and 19, in weight of 5/32-in. stock over that of ⅛-in., while curve No. 5 gives the per cent increase, 26 to 35, for 3/16-in. stock over the ⅛-in.

Fig. 4 is the same as Fig. 5, except for giving variable widths of section with constant depth of 5 in. Here the increase in weight of 5/32-in. stock over the ⅛-in. is from 8 to 12 per cent, and that of the 3/16-in. is from 15 to 24 per cent.

Figs. 3 and 4 tend to show that within reasonable limits of section sizes the lighter gages of stock are the most economical for the same strength of section.

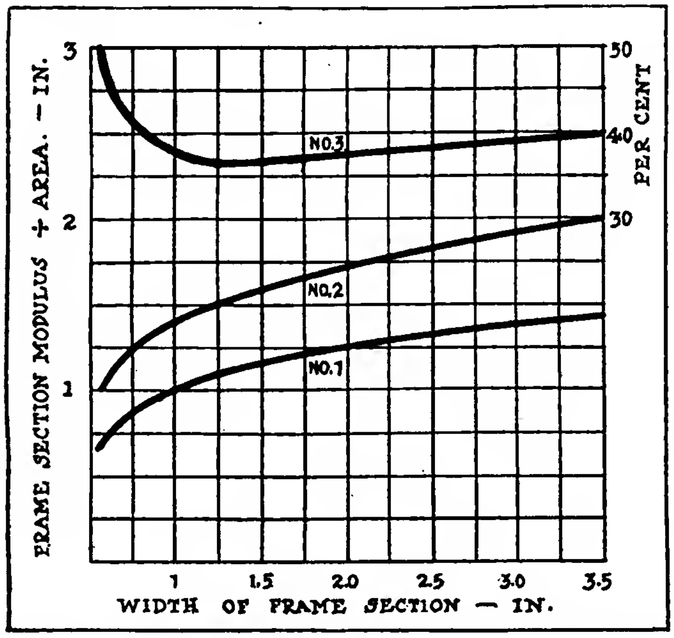


Fig. 1—Effectiveness of metal distribution, 4-in. depth of section compared with 6-in-⅛-in. stock. No. 1, 4-in. depth, No. 2, 6-in. depth, No. 3, % gain 6-in. depth over 4-in.

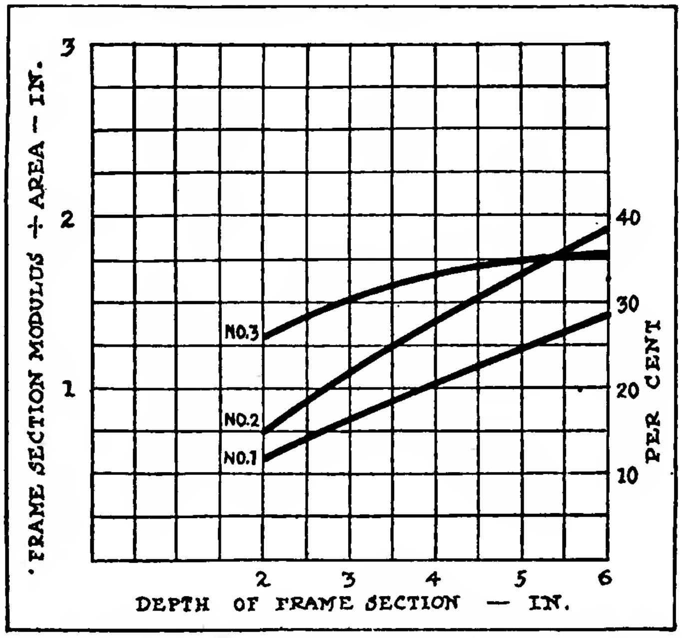

Fib. 2—Effectiveness of metal distribution, 3-in. width of section compared with 1-in., ⅛-in. stock. No. 1, 1-in. width, No. 2, 3-in. width, No. 3, % gain 3-in. width over 1 in.

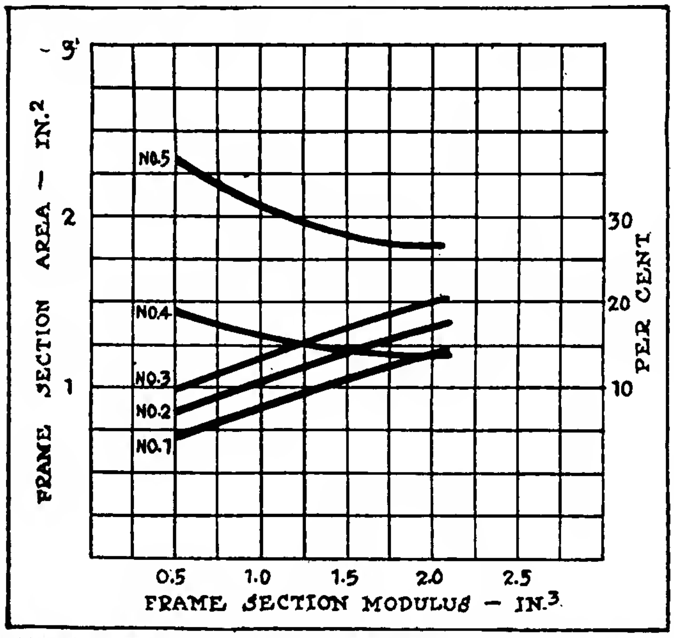

Fig. 3—Weight per unit length—strength comparison. Sections 2-in. wide. No. 1, ⅛-in. stock, No. 2, 5/32-in. stock, No. 3, 3/16-in. stock, No. 4, % increase in weight of 5/32-in. stock over ⅛-in., No. 5, % increase in weight of 3/16-in. stock over ⅛-in.

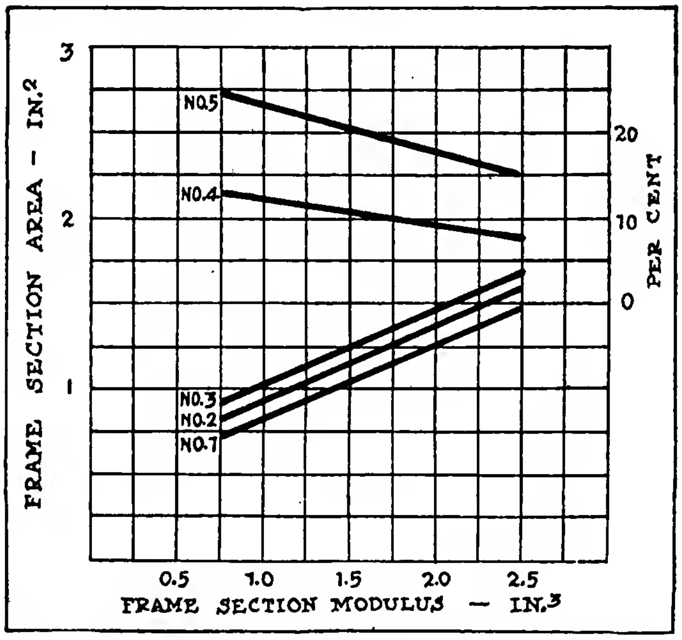

Fig. 4—Weight per unit length—strength comparison. Sections 5-in. deep. No. 1, ⅛-in. stock, No. 2. 5/32-in. stock over ⅛-in., No. 5, % increase in weight of 3/16-in. stock as compared with ⅛-in. stock.

Detroit S. A. E. Holds Big Meeting

K. W. Zimmerschied Receives Presentation—Short Discussion Follows Paper on Trend of Automobile Design

DETROIT, Feb. 16—In the paper read here to-night before the Detroit Section of the Society of Automobile Engineers on the "Trend and Possibilities of Automobile Design" by A. Ludlow Clayden and L. V. Spencer, editorial department Class Journal Co., the large audience was particularly impressed with the plea made for the development of engines which would efficiently use cheaper and heavier fuel. This was suggested as the logical means of combating the advancing cost of gasoline. Extracts from the paper were published in the Feb. 17 issue of THE AUTOMOBILE.

Before the presentation of the paper by Mr. Clayden, Russell Huff, President of the Society, made an address in praise of the work of K. W. Zimmerschied, metallurgist of the General Motors Co., who resigned as chairman of the Standards Committee of the Society, owing to the press of other work. In token of appreciation of his work a framed copy of a resolution of thanks, which was passed by the council, was presented to Mr. Zimmerschied, and on behalf of the members of the Council and of the Standards Committee he was given a leather desk set as a further mark of their high regard for his work and for himself.

Large Attendance

The attendance was perhaps the largest yet enjoyed by the Detroit Section, and several of the automobile centers near Detroit were represented by good-sized delegations. Fifty student members of the Michigan University Section of the Society also came in from Ann Arbor for the occasion.

Discussion Short but Animated

A. P. Brush, Brush Engineering Association, stated that he believed Mr. Clayden had come to an erroneous conclusion when he said:

"I must preface my remarks in connection with certain points in Mr. Clayden's paper, from which I differ, by expressing a profound admiration for the able manner in which Mr. Clayden has handled an exceedingly difficult subject, an admiration which I am confident I share with everyone present this evening.

"Mr. Clayden makes some remarks regarding the future of heavy oil engines for automobile service, and concludes his remarks in this connection with this statement: 'But it has got to be done somehow, the thing has got to be faced and the sooner it is faced squarely the sooner it will be over.'

"Mr. Clayden's reason for this conclusion is expressed in a previous paragraph in this language: 'A practically inexhaustible supply of fuel from which to draw.'

"I believe Mr. Clayden has come to an erroneous conclusion, because he considered only one of the two obvious solutions; that is, the origination of a new type of engine capable of using satisfactorily less volatile hydrocarbon fuels with equal satisfaction to the operator.

Expects Chemical Solution

"It is a well-known fact that the less volatile hydrocarbons are made up of the same two elements, hydrogen and carbon, but with an excess of carbon, and if, or when progress in synthetic chemistry enables us to add the necessary hydrogen and secure a molecular reconstruction, a greater amount of more volatile fuel will be secured than the original amount of the less volatile crude product.

"Mr. Clayden refers briefly to a somewhat unusual use of the conventional leaf spring for car suspension. Being somewhat familiar with this construction, I ask your indulgence for the purpose of amplifying Mr. Clayden's remarks somewhat and correcting an erroneous impression which some engineers and laymen have formed regarding it.

"Because the construction referred to is a compounding of two semi-elliptic springs arranged transversely to the axis of the car, the two springs being attached to each other at the center, it is commonly assumed that, owing to this center attachment, this suspension will not resist the tendency of the car body to roll from the effect of centrifugal force on turning a corner, as much as the more common arrangements of springs arranged longitudinally at the sides of the car.

"A mathematical and geometrical consideration of this suspension will readily show what the most exhaustive tests have demonstrated in practice, that it is better adapted to resist this rolling tendency than any of the other leaf spring arrangements now in use. I might also add that any riding characteristics achievable with any of the other known types of leaf spring arrangements can be at least duplicated and with a lesser amount of spring steel and a much better loading of the rear axle structure.

Detachable Cylinder Head Best in One Piece

"Mr. Clayden calls attention to the advantages of the detachable cylinder head, but comes to some conclusions regarding it, which in my judgment are not sound, in that these conclusions seem to be based upon an over-valuation of certain hypothetical advantages.

"For example: it does not seem to me sound logic to overemphasize the need of extreme rapidity in removing and replacing a detachable cylinder head.

"There are normally only two reasons for removing the cylinder head in service. They are carbon deposits and deterioration of the exhaust valves. Primarily the use of a properly controlled oiling system instead of the horribly unscientific compromise systems which are still too common, and, secondarily, a little care to avoid running the engine with too rich a mixture would eliminate the need of cleaning carbon oftener than once per year of average service.

"Exhaust valve deterioration decreases rapidly and the power output per cubic inch of piston displacement increases rapidly with a proportionate decrease in cylinder and valve sizes.

"If, therefore, as I am confident, cylinder head removals can be reduced to an average of not more than one per season, I fail to see how the saving of *all* of the time necessary to remove a bolted-on head can be any large advantage to the user.

"I must also take exception to the conclusion of Mr. Clayden expressed in the following quotation on page 11: 'In nearly every case half the advantage is thrown away by making the detachable head in one piece.' Where the detachable head carries with it the valves, thus permitting valve grinding at the bench instead of in the car, I believe the one-piece head is a distinct advantage, inasmuch as all cylinders and all exhaust valves will need attention, in a well-designed and constructed engine, at least approximately at the same time, and this construction permits a quick interchange of heads, giving the user the maximum of service in the minimum of time and allowing the garage mechanic to do his valve grinding between times.

"Mr. Clayden calls attention to the inherent accessibility advantage in the adjustable fulcrum overhead valve mechanism, but goes on to say: 'There are many pros and cons for the valve-in-the-head construction.' In this matter I am frankly a partisan, so much so, in fact, that I am quite incapable of appreciating the 'cons' of the overhead construction of the type referred to.

"Of course, I realize that the older types of rocker actuated overhead valves have been so badly carried out that the kinetic energy of the reciprocating valve parts was so high as to seriously interfere with the quietness and flexibility of the engine. Not only that, but the failure to understand the possibilities of proper rocker construction has prevented the securing of other important advantages in the whole valve mechanism.

"Considering the adjustable fulcrum, multiplying rocker valve train in which the multiplication ratio of the rocker is two to one, several things are apparent.

"First, the cam form is such that the flat surface cam rider or tappet may be used with safety. Second, the adjustment of valve train backlash disappears from the moving parts, permitting the use of the thimble type of cam rider or tappet in its best and lightest form. Third, the kinetic energy of the cam rider or tappet and the push rod is only one-quarter what it would be without the use of a multiplying rocker. Fourth, the weight of the reciprocating parts is lower than it could be without the use of the adjustable fulcrum for the rocker.

"These four characteristics are the prime reasons for the quietness and durability of this type of mechanism, particularly at high speeds. It is a fact that the flat-ended cam rider or tappet with a proper co-acting cam has characteristics which make it inherently better adapted for high speed work than the more expensive and heavier roller type of tappet, but for reasons clearly apparent in the second diagram, the flat-ended cam rider calls for a cam form which does not work out advantageously without the use of the multiplying rocker or its equivalent.

"I believe that the overhead valve engine, if properly designed and constructed, is from every standpoint the superior of any other type of poppet valve engine, especially in the hands of the average automobile user. So naturally, I cannot agree with Mr. Clayden that 'There are many pros and cons for the valve-in-the-head construction.'"

McCulla Likes Seat Back Straight

W. R. McCulla, engineer of the Packard company, in commenting upon the criticisms in the paper of the straight backs to the seats in the average car, he said that he had noticed a great many high speed cars recently, both in France and England, and in the majority of cases where they have some form of sway-back seat, such as is advocated in the paper, the driver always had a cushion behind him. Europeans have quite universally known and adopted the low-seated car, said

(*Concluded on page* 379)

New Headlight Mountings Are Rigid

Conditions of Heavy Lamp and Sightly Support Met by Scientific Distribution of Material—Vibration Must Be Dampened by Bracket System

CASUALLY it would not seem that the mounting of the headlamps had a marked effect on the satisfactory condition of the car, and yet if the work is done improperly the headlamps can be the first parts of the car to cause trouble and to indicate that the vehicle has passed its first stage of youth. In mounting the headlights it is necessary for the sake of harmonious appearance of the car that heavy and unsightly brackets do not protrude themselves to such an extent that they catch the eye as something apart from the general lines of the car. At the same time the lamps which are of considerable weight must be rigidly supported.

Bad Effects of Vibration

These two opposing conditions, the heavy lamp and the slender support, give rise to the damaging vibration which oftentimes causes a rupture of the lamp support and necessitates a patchwork job to again restore the lamp to its normal position. When the car passes over the road, striking all sorts of obstructions, vibration is set up which is transmitted particularly to rigid bars in the form of a pillar supported at one end and free at the other. It is in this condition that maximum vibration effects are obtained, and when the lamp is mounted on such a pillar, the full effect of its weight is felt and the supporting structure is soon broken down unless it is so rigid that it is unaffected by the shocks imparted to it.

It is not uncommon, where the lamp has been supported by a bracket bolted directly to the flange of the channel bar frame side member, to see the entire part of the flange of the channel beam broken away due to fatigue brought on by the continued stresses set up by vibration of the lamp support carrying its relatively heavy load.

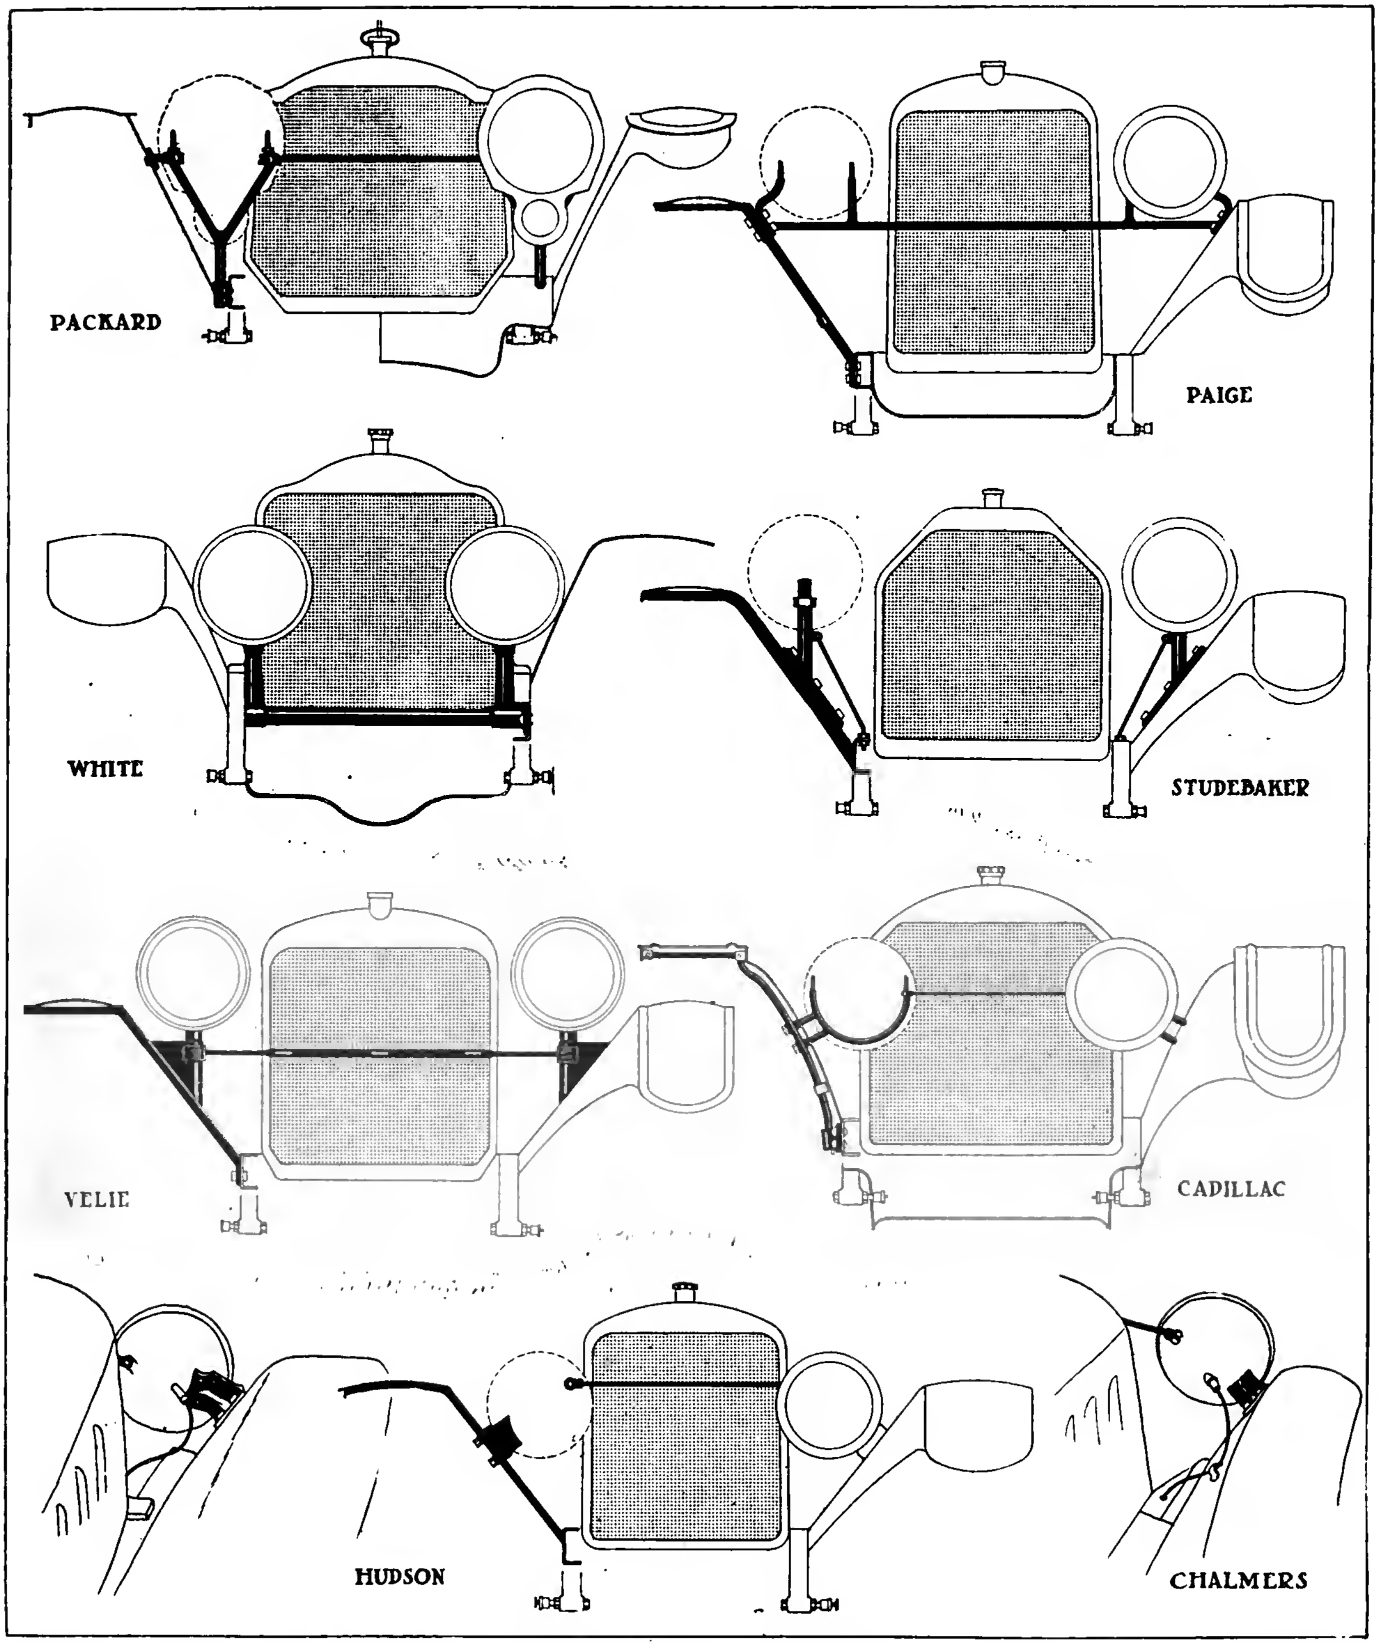
There are two ways in which the stresses can be met and an analysis of the sketches shown on the opposite page brings these to light very clearly. First: The vibrations can be described by eliminating the pillar effect by a cross bar between the two supports. The vibration will then be destroyed, because it would be impossible on account of the differences in synchronism between the two pillars which offset the vibrations by means of the cross support. The second method is by making the lamp supports so rigid that the vibrations are not capable of fatiguing the material.

Examples of where the cross bar method is used are shown in the Packard, Paige, Velie, Cadillac and Hudson cars, while the stiff structure which in itself is capable of resisting vibration is shown in the White and Studebaker. In the White care a stiff tubular structure gives rigidity and at the same time, although there is no cross bar between the lamps, there is a cross connection at the bottoms of the lamp pillars.

High Mounting Favored

There are some very interesting installations also, that are not shown in the accompanying group, although these are quite typical and are indicative of the basic methods of rigid bracing with a minimum amount of metal. It will be noted in passing that there is quite a tendency to keep the lamps high to give a good spread for the cone of light, and there is very little tendency to tilt the lamp downward in order to bring the rays below the eye level of pedestrians. The tilted lamp is at best a makeshift and not a scientific method of meeting the glare problem. It is not surprising, therefore, that it has not found favor and the dimming bulb still retains its popularity with the main lamp designed to cast a beam far in advance of the car.

Headlight Bracketing on Typical Cars



As shown in the above illustrations, there are two systems of headlight mounting, one in which a cross bar is used, which not only breakes the synchronism of vibration of the two headlight pillars, but also acts as a transverse stiffener and the rigid pillar support in which sufficient metal is used and so disposed as to give perpendicular rigidity without cross bracing. Packard, Paige, Velie, Cadillac and Hudson are good examples of different systems of cross bracing, some of the transverse bars being attached to the lamps themselves and others to the supports. Typical supports which are rigid enough in themselves not to require a transverse bar are shown by the illustrations of the White and Studebaker.

Thomas Aero Motor Compact and Powerful

New Small-Bore, High-Speed Eight-Cylinder V-Type Develops 135 hp.—Crankshaft Speed 2000 r.p.m.—Valve Caps Water-Cooled—Aluminum Intake Manifold

SMALL-BORE high-speed motors are going to be the ultimate power plants in aviation work as well as in automobile practice, according to the views of the Thomas Aeromotor Co., Inc., Ithaca, N. Y., which has recently brought out a new eight-cylinder V-motor of this description. According to the claims of the manufacturer, it will develop 135 hp. and yet its dimensions are but 36 in. in length between front and rear gear cover plates and 28 in. in maximum width. The crankshaft speed is 2000 r.p.m. and the propeller shaft operates through spur reduction gears at 1200 r.p.m.

Aeronautical and automobile practice are paralleling each other in simple and accessible grouping of accessories, and in this respect the Thomas motor is thoroughly up to date. In general appearance the new motor is not unlike the conventional eight-cylinder 90-deg. automobile motor. The cylinders are L-head design, 4-in. bore, 5-in. stroke with 1⅛-in. valves of tungsten steel. A feature in the cylinder design which stamps the motor as different from automobile practice is the water-cooling of the valve caps, access to them being by the removal of aluminum cover plates.

The valve springs are of large diameter and of fairly heavy section to prevent floating of the valve at top speeds. Other details of the cylinder design which are worthy of attention are the generous proportions of the cylinder feet and the closeness of the studs to the cylinder bores. The method of holding the push rod guides in an extension of the cylinder feet is also interesting.

High Volumetric Efficiency

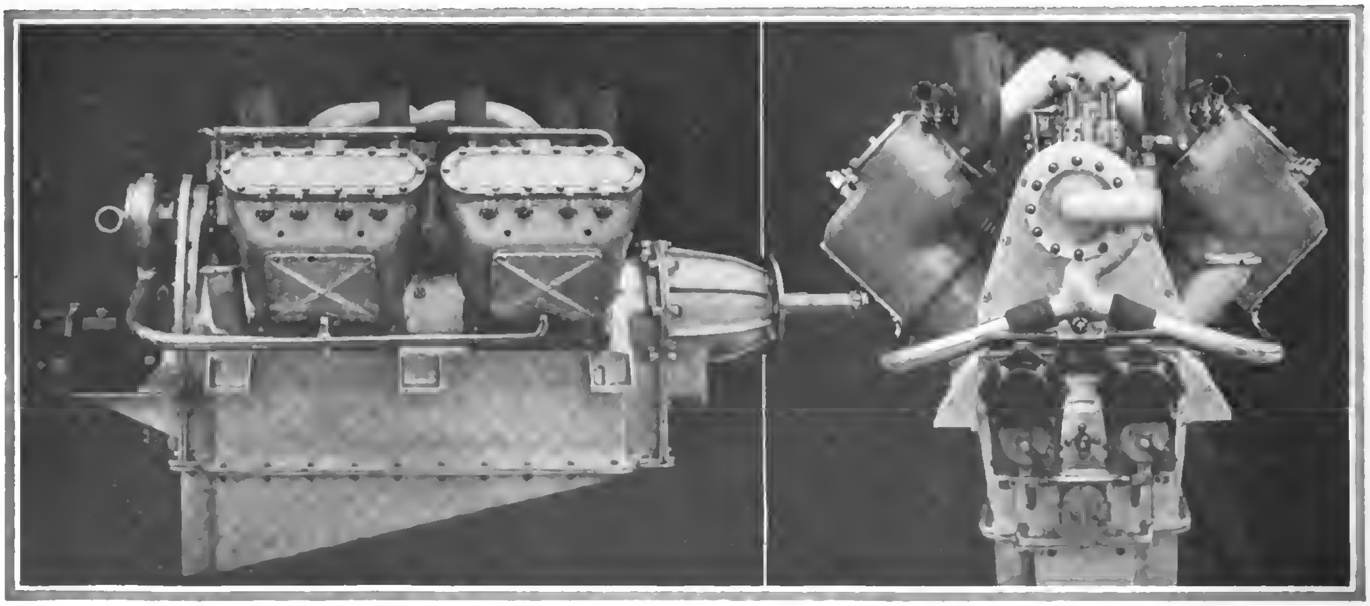
In working out the design of the valves and manifolds particular attention has been given to secure accurate action and high volumetric efficiency. The push rods are of square section and work in broached aluminum guides. They are acted upon directly by the cams without intermediate rockers or followers and are drilled hollow to secure light weight.

An aluminum intake manifold is used which is fitted to a 2-in. double-barrel Zenith carbureter. One nozzle and jet takes care of one block of cylinders and efforts have been made to eliminate bends in the gas passages. The result of this installation is shown in the economy which is claimed to be a consumption of but 13½ gal. per hour. One water pump is used with a siamese outlet to the cylinder jackets. The starter is located in the V with its shaft extending through the gear housing and carrying on its outer end the centrifugal water pump rotor. Two Dixie magnetos are run at crankshaft speed, with four plugs per cylinder.

Force-Feed Lubrication

Oiling is by force feed with the lubricant delivered at 60-lb. pressure. Crankpins, webs and main journals are drilled so as to carry oil to the lower connecting-rod bearings which are side by side arrangements. The pistons, which are of a special aluminum alloy, are lubricated by oil thrown from the crankpins and in order to maintain the oil temperature within the proper limits there is an oil cooling system with a circulating gear pump entirely independent of the lubricating system. The oil in the sump is taken by this separate gear pump and passed through cooling coils exposed to the air stream from the propeller and this again delivered to the sump. Means are provided for shutting off this oil-cooling system in cold weather.

As would be expected in aeronautical use, light-weight reciprocating parts are a necessity. The connecting-rods are of H-section made of chrome-nickel steel machined on all sides. They are 11⅜ in. between centers and the webs and flanges are but 5/64 in. in thickness. A complete assembly of piston, piston pin, connecting-rod and connecting-rod cap weighs but 3¾ lb. The babbitt is applied directly to the steel at the lower end of the connecting-rod. The crankshaft is supported on three bearings.



Two views of the new Thomas eight-cylinder aeroplane motor. The valve caps are water-cooled, being rendered accessible by the removal of the aluminum cover plates

The FORVM

THE AUTOMOBILE'S SUGGESTED IDEAL BODY PROPORTIONS MEET WITH GENERAL APPROBATION—FURTHER CONSIDERATION OF THE TRACTOR PROBLEM

Public Must Be Considered in Body Design

By R. W. Strickland

Chief Engineer Peerless Motor Car Co.

IN regard to Mr. Schipper's article in THE AUTOMOBILE for Feb. 3, such publicity is excellent, but may be misleading unless all the factors in the case have been considered.

For instance, the doorway from which the measurements are taken is not the regular entrance door and is suitable only as an emergency entrance and exit. Of course, the greater distance allowed there the better for the driver, who occasionally gets out in the middle of the street and not on the sidewalk.

In our design we gave what we considered sufficient clearance for entrance and exit without deforming the side of the body and relative proportion of the front and rear doorways, and also without making the right-hand door and front pillar different from the left-hand side. If the left-hand door is widened to give the extreme clearance called for it will be out of proportion with the possibilities of the rear door width unless the front pillar is retired. This is impossible on the right-hand side, as the distance between the front of seat cushion and the front pillar has to be kept at a fixed minimum to facilitate normal entrance.

In regard to the position of the levers, the point of reaching for the levers has been exaggerated. Also the position of the driver which you assume, as most real drivers prefer an upright position to the reclining one. Furthermore, in retarding the change speed and brake levers when located in the center of the car for right-hand control with left-hand drive, the further they are retired the less foot room is left for the driver getting into the seat from the curb side.

Bent Levers Undesirable

A comparison, of course, may be suggested in the way of bent levers, but such things nowadays are being avoided from a manufacturing and service standpoint and I have no doubt that most of the manufacturers have weighed these conditions carefully in locating their levers.

In regard to the brake lever, other difficulties enter—that is, plenty of throw is required in order to set the brakes with power and at the same time provide sufficient clearance to prevent dragging. This means that if the forward position is moved back within very easy reach the "on" position will be past center and a great inconvenience to people getting in and out of the car with the brakes set.

As for engineers getting together on fixed set of dimensions for these points, I believe it would be well-nigh impossible, owing to the balancing of the various points brought out in your article and the points above, which call for compromises to suit the general public.

I believe we sent in the dimensions of our Model 56, which is probably one of the cars measured mentioned in your article.

In regard to folding wheels, we have noted carefully on one model which adopted them that the drivers never used them in spite of the fact that it was a little difficult to get out on the "off" side, but it was more difficult to fold the wheel, even though the device was fairly simple.

Working on Adjustable Seats, Toeboards, Door Locations, Etc.

By G. G. Behn

Chief Engineer Hudson Motor Car Co.

MR. SCHIPPER has covered a good many important points in connection with the design of automobile bodies in his article appearing in THE AUTOMOBILE for Feb. 3.

Undoubtedly, the reason that so many bodies are designed with improper seating space or entrance space is because the the body is usually the last item which is given any consideration. A chassis is first designed and wheelbase determined, and after this has all been done then the body is designed. In a great many cases insufficient space is allotted for the body, which brings about the crowded conditions mentioned in Mr. Schipper's article.

We have been working for some time on a scheme of determining sitting positions and door openings which will enable us to get conditions exactly as they will be reproduced in the finished body, including the upholstering. In other words, the seats, toeboards, door locations, etc., will all be adjustable. When completed, we believe that the device will be very valuable, as it will eliminate all guess-work as to what is correct in the way of body dimensions.

To Develop Light-Weight Ploughs

By Marius C. Krarup

IN this column, issue of Feb. 10, I mentioned some reasons for the belief that the development of light tractors and the use of light motors for farm work, to take the place of the heavy machinery or of the animals now employed, depends wholly upon the simultaneous development of soil-milling tools and methods, by which the movements for working the soil are made to assist in the propulsion of the machine.

You omitted, however, my closing paragraph, for the sake of which the rest was written. No doubt, the omission was due to the exigencies of your space. What I suggested was that the most practicable way for developing light soil-milling machines for use on farms, where they cannot be adopted unless they are sure to pay for themselves from the start, is to gain experience by designing and building them in sizes and types suitable for suburban gardens, whose owners are not so closely bound to either economy or ownership of the machines. While my suggestion was not worded more explicitly, I assumed that every American familiar with suburban and village life in the United States would at once see a picture projected on the movie-screen of his own mentality to the effect of some enterprising young business man in the locality making suitable arrangements with a maker of soil-milling machines, on one side, and with owners of gardens and garden truck farms, on the other side—enabling all to get their soil tilled at a fair price and in quick order, each successive year getting the advantage of improvements in the construction of the machines without the burden of individual investment. I could go much farther with this suggestion, as regards construction as well as in the industrial and sociological features, but fear to encroach on your space with a subject in which only a minority of automobile manufacturers, engineers and users are interested.

Where would the automobile industry be to-day, however, if the public had not carried the main burden of experimental work from 1895 to 1903? And—assuming that soil-milling as distinguished from plowing, is necessary to let the automobile industry into the manufacture of farm motors and tools—how many years will it be likely to take before good results are reached, unless the burden of constructive experimentation is distributed somewhat, as may be done on the plan suggested? The new-born enthusiasm for fancy farming and gardening under the auspices of city people, for which the automobile is largely responsible, should be like mother's milk for the infant soil-milling machine.

Detroit S. A. E. Has Big Meeting

(Concluded from page 360)

he, but he noticed the drivers all hanging on to the steering wheel, sitting up quite straight. He also remarked that he has sat in a few cars himself at high speed which had a low back seat and does not like it.

E. T. Birdsall, Kosmath company, speaking on the matter of body comfort, heartily endorsed a recent article in THE AUTOMOBILE entitled, "Drivers Lot 99 per cent Discomfort." He agrees with the idea of making an effort to put more comfort into the bodies. At the Detroit show, Mr. Birdsall remarked, he went around with a friend who was going to buy a car and tried four of the very well-known makes, and in not one of them could he sit in the front seat, put his feet on the pedals and keep his knees away from the steering wheel. He said that comfort is a point that designers would do well to pay a great deal of attention to.

Chase Favors Transmission Brake

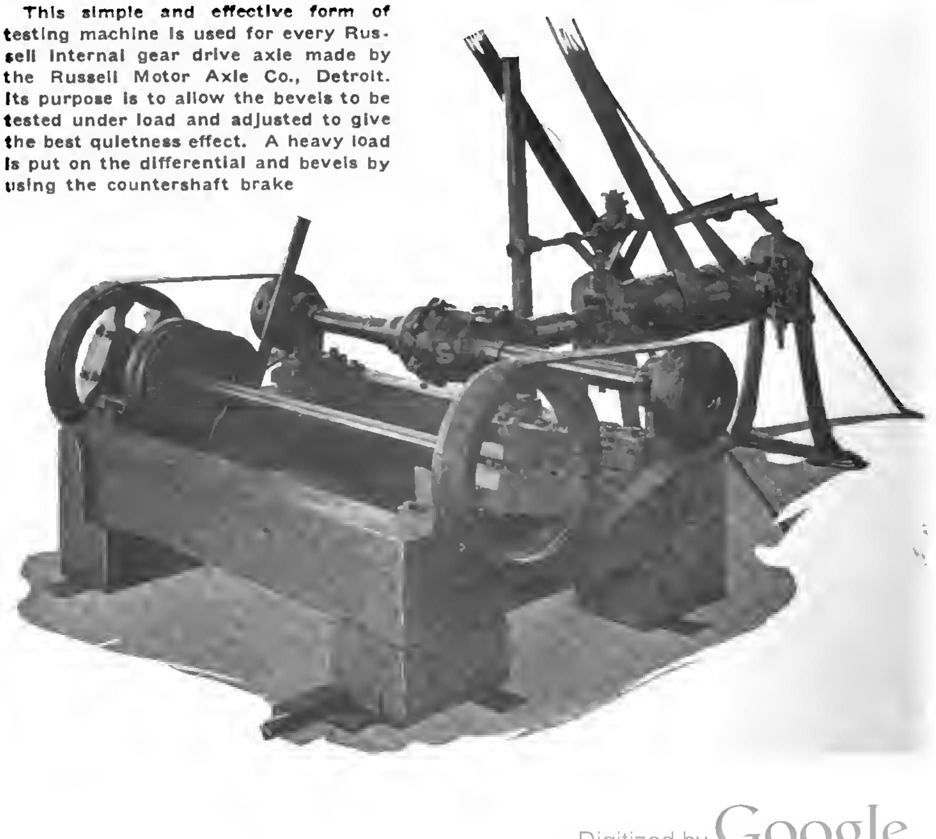
Regarding brakes, which were also dealt with in the paper, Herbert Chase, laboratory engineer A. C. A., spoke in favor of the propeller shaft type. "It is not very much seen in American cars, but it has some possibilities which warrant more consideration. There is also another point which, perhaps, should have quite a little emphasis, and that is the very poor average carburetion that we have on cars. I think it is safe to say that perhaps 10 to 15 per cent of the fuel that is used is never fully burned, and the products of combustion contain large quantities of CO which in itself is a mark of decided inefficiency in carburetion. I look for improvement in that line.

J. G. Vincent, chief engineer of the Packard company, touched upon the body-seating matter and said that while he personally was in favor of the low arm-chair type of seats, it is his experience that the higher seated cars sell more readily. For rough roads he thinks the fairly straight seat more comfortable because it allows one to brace himself to better take the bumps. The remarks regarding brakes, Mr. Vincent thinks, are very timely and that engineers must put more study on them. He thinks front wheel brakes are fine in theory, but they have the objection of increasing the turning radius which, of course, is not desirable. On this point Mr. Vincent said that someone may get up a mechanism to operate a front wheel brake and still keep a short radius, and it would certainly be a good thing. He also commended the steering qualities of the average high-grade car to-day.

As to the matter of transmissions, Mr. Vincent said that he could not possibly agree with the paper where it says there is going to be any tendency toward hydraulic or electric transmission. After looking the situation over thoroughly he believes the answer to be along the lines of a flexible motor. As to the aluminum motor, he said, this is certainly a very interesting development. There are no doubt some things to be solved in it, such as keeping it properly warm in the winter time, not having to take too much time to warm it up, and so forth. Regarding the statement in the paper that power falls off badly in a motor of small cylinder bore, he stated it to be his opinion that the power falls off in a larger percentage in a larger cylinder, on account of the larger valves and the inability to keep the valves in good shape.

Importance of Heavy Oil Experiments

There was very little time left for the author's reply, and Mr. Clayden confined his attention to the question of heavy oil experiments. He stated that he had observed so many disappointments in the development of chemical methods for making gasoline from heavy oil that he had lost faith in chemists. If the high price of gasoline is due to shortage the heavy oil engine is a necessity, and if the price is not due to shortage, then the coming of heavy oil engines will force those responsible for holding up gas prices to ease them off again. Either way there is advantage in developing heavy oil automobile engines as rapidly as possible.



This simple and effective form of testing machine is used for every Russell internal gear drive axle made by the Russell Motor Axle Co., Detroit. Its purpose is to allow the bevels to be tested under load and adjusted to give the best quietness effect. A heavy load is put on the differential and bevels by using the countershaft brake

Milwaukee—Le Roi Motor Designed for Simplicity

Few Moving Parts with Integral Construction Used Wherever Possible—Thermo-Syphon Cooling, Unit Crankcase and Cylinders with Detachable Heads

UNDER the model name Le Roi, the Milwaukee Machine Tool Co., Milwaukee, Wis., has brought out a motor which it has designed especially for simplicity. The motor is for light work, and the brake-horsepower curve shows the motor to reach its peak at about 2300 r.p.m. at which speed it develops about 28 hp.

Moving parts have been cut to the minimum possible with present design and what moving parts there are are completely inclosed when the engine is in the car. The cylinders and crankcase are cast in one piece, and in addition to the rigidity which this construction gives to the engine, tending to prevent cramped bearings and crankcase warping, the bearings themselves are of ample dimensions. This gives a simple rigid structure which is a sample of the policy followed throughout the entire design.

Convection Cooling Employed

Cooling is by thermo-syphon with special attention given to the water spaces around the valves and cylinders. An example of this is that there are no less than fourteen openings between the cylinder and cylinder head through which the water circulates, the head itself being detachable in order to give access to valves, pistons, combustion chamber, etc.

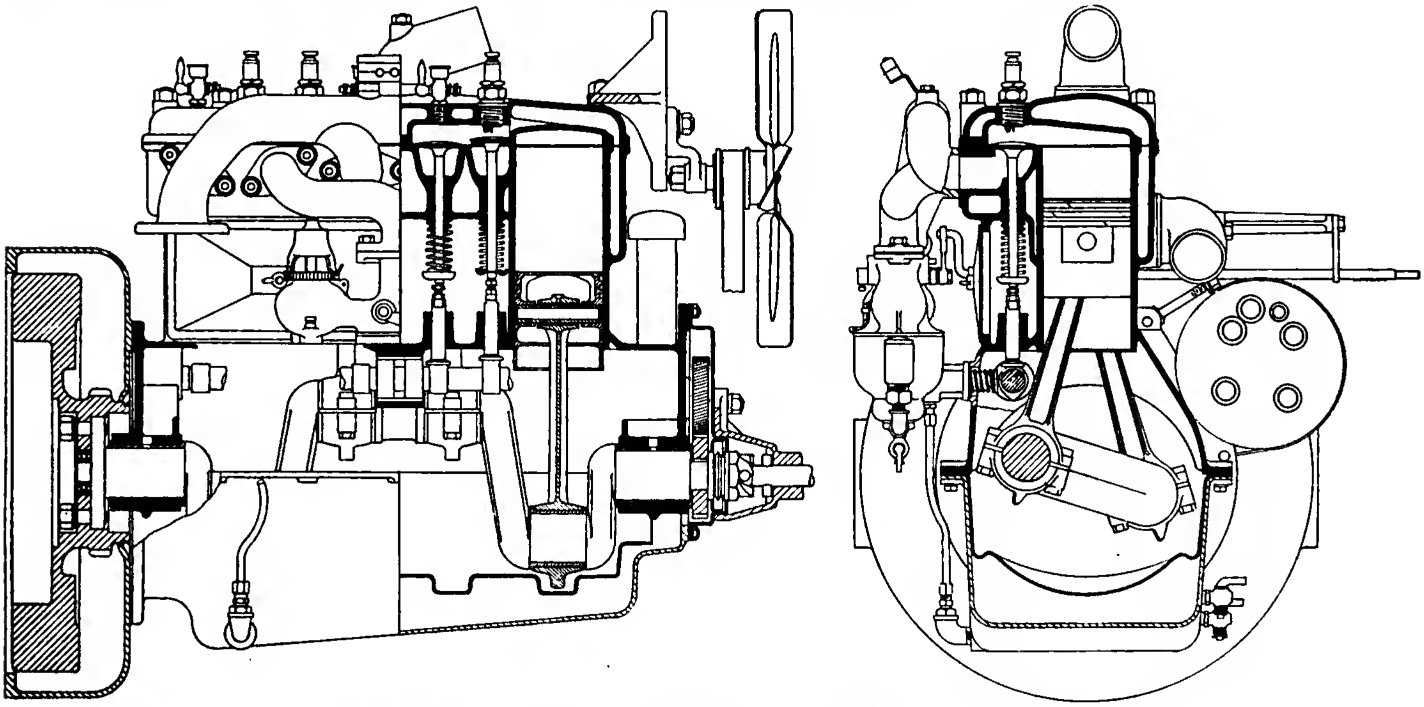
Equal simplicity is found in the lubricating system which is a combination pump and splash. Oil is pumped from the reservoir by a simple positive plunger pump to pockets over the camshaft bearings, whence it flows through the channels provided to pockets over the main crank bearings and from there to the constant level splash troughs and back to the reservoir. The pistons, wrist pins, and timing gears are all lubricated by the spray of oil formed by the connecting-rod splashing into the constant level tray.

Direct Valve Action

Referring to the sectional illustrations, it will be noted that the valve action is simple and direct. The valves are of large diameter and are actuated directly from the camshaft through a mushroom type push rod. Adjustment for clearance is provided in the usual manner between valve stem and push rod. In the sectional illustration the ample water-jacketing space around the valve stem guide is clearly shown.

The cylinders are 3⅛ by 4½ fitted with gray iron pistons closely machined and by careful distribution of the metal as light as possible. The pistons are flush top with three rings above the wrist pin and the piston pins driven into the bosses in the casting. The connecting-rods are I-beam section of light weight and the crankshaft is supported on two main bearings. A spiral gearset drives the camshaft which is of integral construction.

The bell housing for the flywheel is No. 4 S. A. E. standard and there is a ball bearing in the flywheel to support the front end of the transmission driveshaft.



Part longitudinal and transverse sections though the Le Roi motor made by the Milwaukee Machine Tool Co.

The Rostrum

Oil Geology of Goshen Valley, Utah

EDITOR THE AUTOMOBILE:—I notice in THE AUTOMOBILE the price of gasoline steadily advancing, some people giving as a reason scarcity of crude oil. This prompts me to ask a question which I confess is out of your line of work, but since you are interested in automobiles and gasoline you might give me the desired information.

I am living in a valley where there are a number of springs that at times show traces of oil, also an abandoned well on my ranch has shown oil at times to such an extent that stock would not drink from it. Some well diggers have tried to dig wells here and find a layer of rock so hard they cannot get through it with a common drill. One man who had worked with a drill in oil fields said he thought if a person could drill through this layer of rock he would strike oil.

I am told that these indications are very similar to those in the Big Horn Basin, Wyo., where they drilled and found large quantities of oil. This country, to my knowledge, has never been examined by an expert oil man, and any information whereby someone could be induced to make an honest effort to test it out would be very much appreciated. T. L. S.

Elberta, Utah.

—Elberta is located about 9 miles east of Eureka, Utah, in a district which was mapped in detail in 1897 by the United States Geological Survey. The map and associated description are embodied in the Tintic special folio, No. 65, of the U. S. Geological Survey, which is obtainable from the director of the Geological Survey at Washington, D. C. for 25 cents.

The rocks of Goshen valley, in which Elberta is situated, consist of sands and gravels in terraces, bars and deltas, comprising the lake bed series of the extinct lake Bonneville; and they are underlain by andesite and rhyolite lava flows in sheets of uncertain thickness.

As far as it is possible to tell from the general geology, as described in the folio, the area in and around Elberta does not appear to be favorable to the occurrence of quantities of oil.

THE AUTOMOBILE is indebted to the Department of Geology, Columbia University, for assistance in tracing down this inquiry.

Formula for Flow Through Pipes

Editor THE AUTOMOBILE:—I should like to know the principle of operation of a gear pump. Will one operate against a pressure of 5 kg.?

2—What is the formula for determining the flow of a liquid through a pipe? Given a pressure of 5 kg., a pipe diameter of 15 mm., a Saybolt viscosity of 300 sec., please explain fully how to determine the number of liters of oil delivererd per second.

3—Is it possible to make an accurate fit in a dog coupling as shown in the sketch, Fig. 3. I wish to use such a construction in the divided center bearing of a two-piece crankshaft. What method of procedure would it be necessary to employ to make and fit same accurately? F. H. W.

New York City.

—The principle of a gear pump is simple, as it consists merely of two gears rotating within a chamber. The pump chamber is so arranged that the side of the two gears coming into mesh are in the intake compartment and coming out of mesh in the exhaust compartment. The oil is led in, and as the gears come into mesh it is picked up in the clearance space between the teeth and thrown out on the other side. By a pressure of 5 kg. it is presumed that you mean a pressure of 5 kg. per square centimeter. This is equivalent to about 70 lb. per square inch, which is slightly above the capacity of the usual gear pump.

2—Unless you give the pressure in kilograms per square centimeter or some other square unit, it is impossible to interpret your inquiry. There are a great many formulæ for flow of liquids through pipes, depending on the nature of the pipe and various other factors. The theoretical formula for quantity discharge is $Q = ac\sqrt{rs}$, in which a is the area in square feet, c the coefficient of flow, r the mean hydraulic depth or the area over the perimeter, and s equals slope or head divided by length of pipe. To obtain definite values in this formula to substitute in order to secure a definite result, it will be necessary for you to take a hydraulic table and secure your head from your kilograms per square centimeter figure and your other variables from the kind of pipe you are using, etc.

3—It would seem possible to make an accurate fit on the clutch you have sketched in Fig. 3 by grinding the engaging surfaces of the jaws.

Oil Used Probably Too Light

Editor THE AUTOMOBILE:—What is the address of the Northway Motor & Mfg. Co., which manufactures the four-cylinder motor of the model 43 Oldsmobile?

2—Which is the best oil to use in the transmission of the model 43 Oldsmobile? Some tell me to use same as in the motor.

3—What causes the first two cylinders to have poor compression and the spark plugs to be coated with carbon and oil? I use a light oil. It is a valve-in-the-head motor, and the car has run only 1100 miles since it was bought last Fall.

4—Please give me the horsepower curve of the four-cylinder 3½ x 5 valve-in-the-head Northway motor.

5—Does it shorten the life of a storage battery more if it is used for ignition as well as for starting and lighting, or only starting and lighting, if the battery is always kept charged and supplied with water?

6—Which gives the brighter light—a 6-volt lamp or a 7-volt? The battery is a 6-volt storage, and what is the right candlepower to use? Does it harm the battery to use 7-volt lamps? Will a 7-volt lamp burn out as easily as a 6-volt?

7—What per cent difference will a speedometer show that is driven by the driveshaft over one that is driven by the front wheel on the average country roads?

8—Can you give me a sketch or description that will show me how the oil is fed into the different troughs under the connecting-rods, and does it make any difference if machine stands lower in front, as my floor is 2 in. lower? Does it feed an equal amount of oil into each trough? T. A. F.

Kenosha, Wis.

—The Northway Motor & Mfg. Co. is located in Detroit.

2—A heavy oil should be used in the transmission. The oil should be poured in up to the countershaft.

3—Try a medium oil in place of the light. It is hardly possible that the rings are worn as yet.

4—The horsepower curve of the Northway 3½ x 5 overhead valve motor is not at present available.

5—No.

6—On a 6-volt circuit the 6-volt lamp will give the brighter light, although its life will not be as long as the 7-volt. The candlepower can be anything you choose, but the greater the candlepower the more current will be consumed. Lamps which are up-to-date burn about 1 watt per candlepower. It does not harm the battery to use 7-volt lamps, and a 7-volt lamp will not burn out as quickly as a 6-volt on a 6-volt circuit.

7—This figure cannot possibly be given, on account of the great number of varying factors which enter. No doubt, however, if the same car could be equipped with independent speedometers with the two methods of drive, an average figure should be secured, but of this THE AUTOMOBILE has no record.

8—The fact that the car stands on a slope should not affect the oiling system as each trough is fed independently. You can readily test the oil level in the well yourself, as there are four plugs on the right side of the crankcase near the bottom which may be removed and the oil level ascertained.

Hudson Uses Three-Brush Regulation

Editor THE AUTOMOBILE:—Please describe and give advantages and disadvantages of semi-floating, three-quarter floating and full-floating axles.

2—Kindly publish wiring diagram of the new Delco system, third brush regulation, as used on Hudson super six.

New York City. F. W. W.

—See THE AUTOMOBILE for Dec. 2, page 1004.

2—This is shown in Fig. 1.

Connecting Trouble Lamp on 6-42 Kissel

Editor THE AUTOMOBILE:—I have a 1916 6-42 Kissel, and would like to know the best way to connect the wiring to attach a socket on the motor side of the dashboard for an electric trouble extension lamp, the Westinghouse lighting system being used on this car.

Newark, N. J. L. S. H.

—The trouble lamp should be a two-wire type with one wire run directly to the ground and the other wire connected to the tail light circuit. This will leave the socket alive whenever the tail light is in operation and the consumption of current will only occur when the trouble light actually needed is inserted in the socket. If you desire to use the equipment already on the car the instrument light is connected with a removable shelf so that the lamp bulb can be taken out and the plug connection of the trouble light inserted. Therefore, an extra socket is not needed unless you really desire to install one.

Use Graphite Paint to Prevent Rust

Editor THE AUTOMOBILE:—What is the paint to use on the rim of the wheel to keep it from rusting? G. W. C.

Portland, Me.

—Graphite paint is probably the best to use on the rim of a wheel to keep it from rusting.

Information on 1912 Model Everett

Editor THE AUTOMOBILE:—I have recently come into possession of a 1912 Everett model 36 and would like to know what the original equipment was as to ignition, carburetion and transmission systems. I also would like to know the bore, stroke and rating of this engine and the maker's name.

Haverhill, Mass. E. E. S.

—The standard ignition equipment on this car was the Splitdorf and the carbureter was a model H. Holley; the starter system was a Deaco-Prest-O-Lite. The transmission system was an integral part of the rear axle housing manufactured by the Everett company.

The bore and stroke are 4 by 4¾ with four cylinders and a rating of 38 hp. They were manufactured in the Everett company's shop. The cylinders are cast in a block.

Wiring Diagram of Moline-Knight

Editor THE AUTOMOBILE:—Kindly show me by diagram the lighting and starting system of the 1914 series of Moline-Knight.

2—Where is the proper place to connect a spotlight in this car?

3—Could this light be connected to the wires leading directly from the storage battery, if a 12-volt bulb is used?

4—Where should an ammeter be connected in this wiring system?

5—Whenever I refill the battery to the proper level with pure rain water and then charge it by allowing the motor to run, the water in four of the cells starts rising and then almost overflows. I then remove the excess water in these cells after which it does not rise any more. Does this prove these four cells defective or is the water chemically impure; might it be that these four cells are filled up too much, thereby preventing the gas to escape, and then cause this expansion?

Chicago, Ill. E. D.

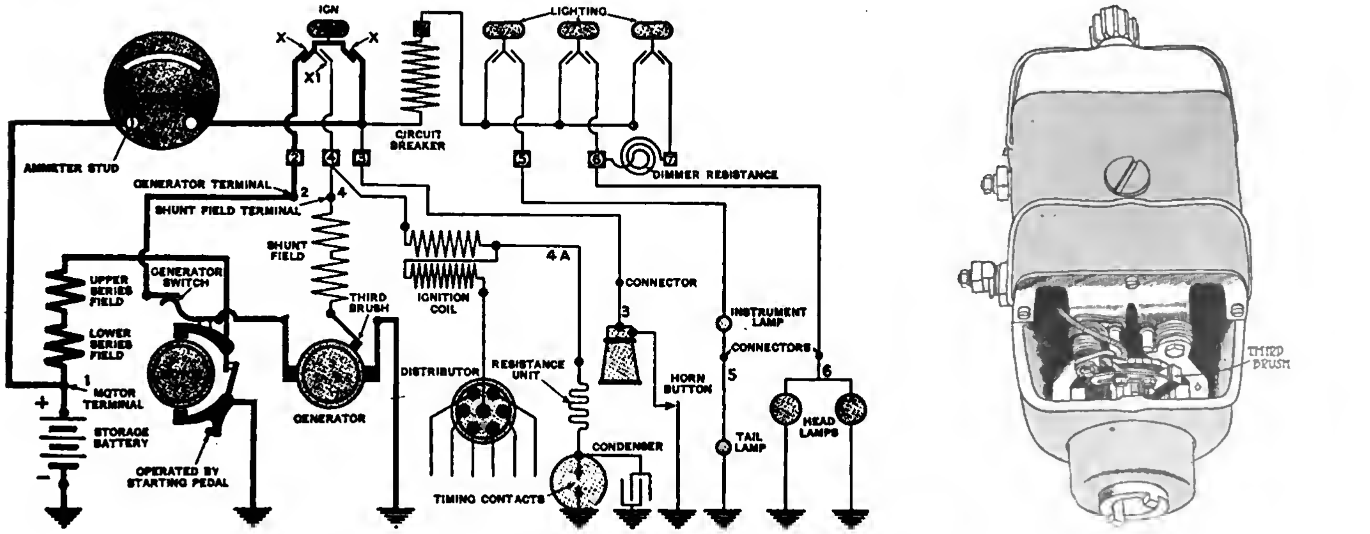


Fig. 1—Wiring diagram and sketch illustrating Hudson-Delco third brush regulation

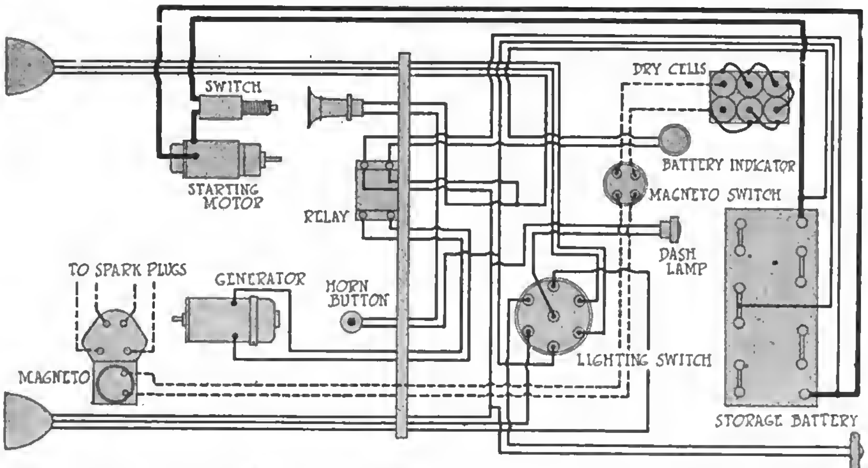

Fig. 2—Wiring diagram of the Moline-Knight with 12-volt storage battery

—The diagram for the lighting and starting system of the 1914 series Moline-Knight is shown in Fig. 2.

2—As there is a 12-volt battery in this car in using a 6-volt bulb the proper thing to do is to connect one side to the neutral side of the switch and the other side to the green or negative wire on the battery.

3—If a 12-volt bulb is to be used it can be connected to the main lead from the storage battery. This is a three-wire cable and the connection should be made on the red and green wires back of the panel board and lighting switch.

4—The wiring diagram shows where the battery indicator should be connected. If an ammeter is to be used in place of the battery indicator the same connection can be utilized. If both are wanted, put the ammeter in series with the indicator.

5—The Moline company uses a six-cell 12-volt battery in this model. If the battery is run down and filled to the proper level with pure rain water the expansion of the plates will cause the water to rise and does not indicate that the cells are not in normal condition. If the water in the other two cells does not act similarly and they contain the same amount of water as the others, it indicates that the solution in these two may be too weak.

Reasons for Slipping Clutch

Editor THE AUTOMOBILE:—I am owner of a six-cylinder car equipped with a disk clutch. The car is geared about 3.3 to 1 with a large wheel and I have experienced trouble in clutch slippage.

Not taking into consideration whether the clutch is too small or not properly constructed, would a lower gear ratio have a tendency to keep the clutch from slipping, or not?

When giving answer will you please give reasons why condition would not be changed or why it would be made better or worse?

Martinsburg, W. Va. C. E. G.

1—A lower gear ratio would tend to keep your clutch from slipping. The reason for this is that the amount of energy through any given period of time transmitted through the clutch is less with the lower gear ratio for a given car speed.

There are two factors in the transmission of horsepower. One is the foot pounds of energy and the other is the time. If the time is increased the foot pounds energy is decreased. Since the revolutions per minute can be considered as a time factor it is quite evident that in transmitting a given horsepower through the clutch the energy at the clutch will be less when the speed of the crankshaft is higher.

Bulbs for Ford Magneto System

Editor THE AUTOMOBILE:—I have a 1916 Ford and am desirous of changing the headlamps. I have a new pair of headlights wired for two bulbs, head and dimmer. I find on taking these lamps apart that the upper bulbs are marked 6.5 volts and the lower ones are 9 volts. I bought these lamps with the understanding that they were for a 1916 Ford. What I wish to know is this: How can I wire these new lamps in series, as the old lamps were, when I bought the car? There are only three wires coming from each lamp. Kindly give diagram.

Allentown, N. J. H. R. D.

—The lamps you have purchased are not the standard Ford lamps and the Ford company has no intention of installing equipment such as this upon its cars. The 9-volt bulbs of your lamps may be wired in series with the magneto but it would be impossible to wire the 6.5 volts to the magneto on account of the low voltage of the lamps which would cause the bulbs to burn out. Storage batteries could be used for the smaller lamps. This is a rather clumsy arrangement, however, and much better results could be obtained by using the standard Ford lamp.

Freezing Point of Charged Battery

Editor THE AUTOMOBILE:—Will a charged storage battery freeze in cold weather? If so, at what temperature?

2—How low does the battery have to be run down before it freezes?

3—How often should a battery be charged when not in use, say, stored for the winter? Some have taken their batteries out of their cars and put them in the cellar. Is it advisable to put them in cellars, or not?

4—Does it injure a battery to let it run clear down.

Plainville, Ill. A. A.

—A charged storage battery will freeze in cold weather an the temperature at which it will freeze depends upon the stat of the charge.

2—Storage batteries will freeze in accordance with the fol lowing table:

Specific Gravity 1.150	Battery empty, 20 deg. below zer
Specific Gravity 1.180	Battery three-quarters discharged zero.
Specific Gravity 1.215	Battery one-half discharged, 2 deg. below zero.
Specific Gravity 1.250	Battery one-quarter discharged 60 deg. below zero.

3—Storage batteries should be recharged at least once a month. Putting a battery in a cellar will not damage i if it is placed in a dry place and where the temperature i known not to go below 20 deg. above zero, and kept full charged.

4—A storage battery should not be discharged below point of 1.7 volts, per cell. A battery is not injured if di charged to this point and immediately recharged. The plate will deteriorate more rapidly if discharged below 1.7 vol per cell and is also injured if left standing in a discharge condition for any length of time.

Ammeter Connection on Chalmers 24

Editor THE AUTOMOBILE:—In your issue of Jan. 2 E. O. H. C. asks about installing an ammeter on a model Chalmers. I have installed on my machine, of the sa model and make, a Weston double scale ammeter reading 10 amp. on charge and 40 amp. on discharge, voltage to 20

By measurement I have found that the maximum dischar on throwing the lever to start is 70 amp. which is only for instant, the needle immediately dropping to below 35. I ha had this installation on my car for two years with perfe success. The circular that comes with the ammeter shows how it should be cut in.

San Francisco, Cal. N. A. Robinson.

Clock to Match Stewart Speedometer

Editor The Automobile:—Could you tell me where I can get a clock to put on my 1916 Maxwell to match the Stewart speedometer that is on it. It is a flush face with narrow nickel rim. It requires a very thin clock, for the space is small between the cowlboard and gas tank. I wish to pay about $6 to $10. The Waltham people supply the Cadillac with a type that would fit only it is too expensive.

Providence, R. I. F. J. R.

—The Stewart-Warner Speedometer Corp. manufactures an electric clock which matches the speedometer. This sells for $15. It is an electric device by means of which one small dry cell will keep the clock wound automatically for six months. It can be installed face flush with the dash and it is believed that there is sufficient room between the cowlboard and gasoline tank on this Maxwell to make its installation possible.

Thomas 35 a 1907 Model

Editor The Automobile:—When was the model 35 four-cylinder Thomas built? What is its bore, stroke, power, weight and speed?

2—I am considering remodeling one into a racer. Is it sufficiently modern to have high grade materials in it? Will two-point ignition from a Bosch double magneto increase the speed?

3—Where can I obtain aluminum pistons for this car?

4—Where can I obtain the right grade of channel steel to strengthen the frame which is continually cracking?

Gallon, Nev. A. D. D.

—The model 35 four-cylinder Thomas was built in 1907. Its bore was 5½, stroke 5⅛ and rated horsepower 60. The Automobile has no record of weight and speed.

2—Yes.

3—Aluminum pistons can now be ordered through any large garage and machine shop as there are now a number of manufacturers.

4—Any low carbon steel will be sufficiently strong to strengthen this frame as the frame in itself must be almost strong enough to sustain the stresses.

Adjusting Willys-Knight Worm Drive

Editor The Automobile:—Will you kindly advise the proper means of adjusting the wheel on the worm drive of a Willys-Knight 1914 car when no index is available?

2—Can the ball bearings of the front wheels be replaced with Timkens without buying new spindles and hubs?

Port Henry, N. Y. F. E. B.

—The adjustment of this wheel is taken care of on each side of the differential by means of shims. It is an adjustment that a repair man should be able to determine readily. The Willys-Overland company states that an allowance should be made of at least 0.005-in., as if the adjustment is too tight a severe binding occurs resulting in the early destruction of the gears. If excessive allowance is used it will result disastrously in that the gears would pound themselves to pieces. In making the adjustment it is suggested that just enough play be allowed to be perceptible between the mesh of the two gears.

2—The Willys-Overland company advises that this can be done.

Lever Slips Out on Rough Roads

Editor The Automobile:—I wish you would publish through the Rostrum a solution that would help me out.

1—My 1914 Packard 2-38 slips out of high gear about every 5 miles if the street is rough, while on country roads it is much worse. I have tightened the top and lower springs that hold the pinion, without results. I have examined the gears and found them as good as new, the connections on the gearbox are all right and it goes in high into full mesh but seems to work out.

2—I have had the crankcase taken off and a 3-in. square piece was broken out behind the starter. Because of the mechanics' failure to take off one of those nuts I had it welded by an expert and the job looked good but in drilling the hole it was cracked about 1½ in. down the side and I am using the car. I don't want to have the car tied up for a couple of days so can you recommend a way that I can temporarily repair it. I have tried shellac but the oil seems to work through.

3—I also have a 1916 Ford. Can a battery be charged from this car's magneto by changing the current to direct? If so, please give full explanations and mention objections if there are any.

Reading, Pa. C. E. A.

—The strongest probability is that the two plungers that drop into grooves in the gear shifter shaft to retain it in any of its four positions are not operating properly. It may be that these plungers have frozen in their guides or that their points have been badly worn, but it is more probable that when the shift to high is made the second speed pinion bottoms in the internal clutch of the direct drive gear before the proper lock groove on the shifter shaft has come squarely under the plunger. If this is the case the rear rod to the shifter shaft may be disconnected and the shaft screwed into the shifter fork until there is left 1/16 in. for travel of this mechanism after the lock plunger has dropped into the clutch but before the second speed pinion bottoms as above described.

If any of the above possibilities should exist it is very possible that in going over uneven roads the driving pressure on the gears might stop momentarily at the sudden slackening of the motor speed just when a sufficient jolt to throw the gears out of mesh was received.

2—From the description given the exact location of this crack is not evident, but the chances are all for its being readily accessible although the motor is in the frame. If so, it would be but a half hour's job for an experienced man to warm up the spot to the proper temperature, clean it and fill the crack very nicely with aluminum solder. Care in using the solder must be taken to avoid oxidization.

3—Yes, by installing a rectifier, but this would be so expensive and troublesome that it would not be worth while. It is not a practical thing to do.

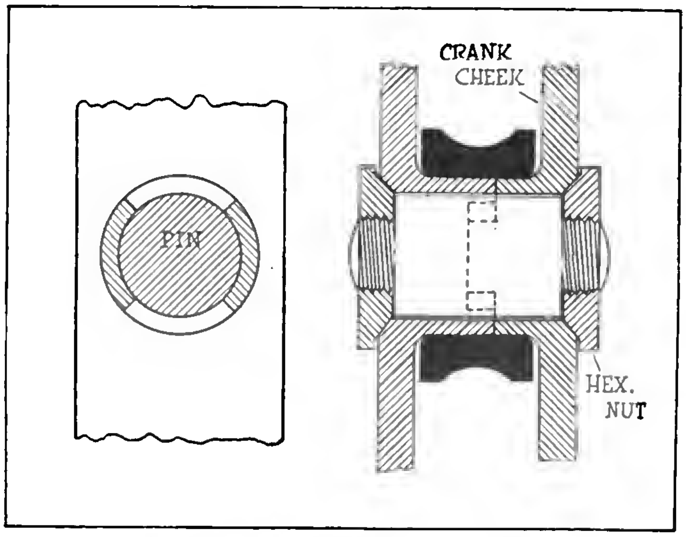

Fig. 3—Suggested jaw clutch for crankshaft connection

The History of the American Automobile Industry—18

Use of Hot Tube and Catalytic Ignition—Perry's Double-Acting Engine Which Resembled a Steam Design—First Induction or Step-Up Coil Invented by Ruhmkorff in 1852 Wins Napoleon's Prize

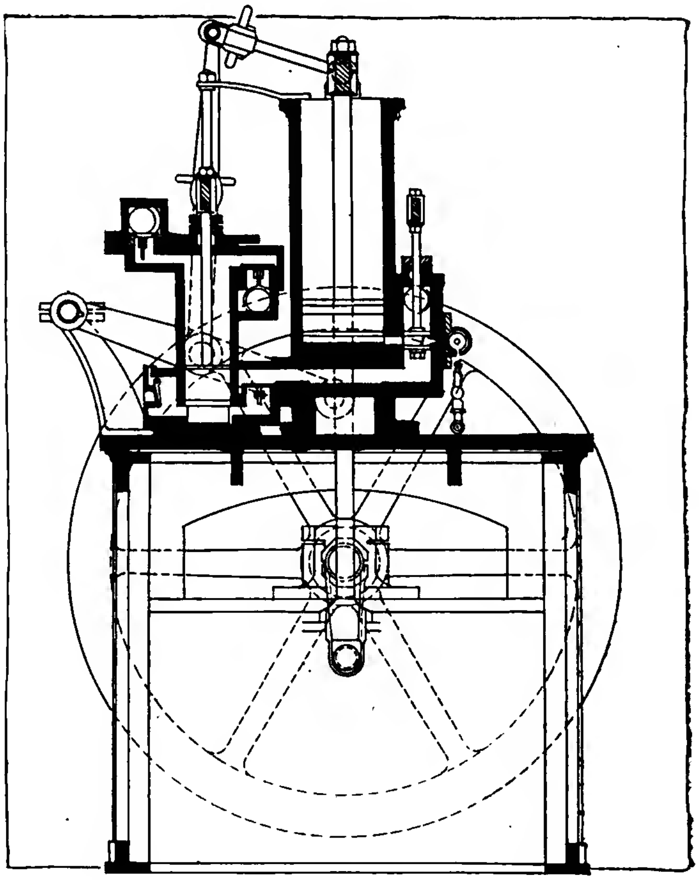
By David Beecroft

IN his British patents, 1615 to 1838, William Barnett shows several valuable ideas. He tried to introduce compression, although it is doubtful if he succeeded in securing much compression in the cylinder, owing to some delay between the ignition and the closing of the admission mechanism, during which time the piston was moving away from the ignition end, and thus reducing the compression.

It was common to ignite the non-compression engine by a flame on the outside of the cylinder and a hole through the cylinder wall, which was uncovered by the piston, after it had moved far enough to get in a partial charge. Some power naturally escaped through the hole, and Barnett, by his devices overcame this objection. He introduced the igniting plug or cock which would be filled with gas from the cylinder, turned round to the flame and ignited and again turned back to the cylinder, where it transferred the flame to the working charge. This igniting device was much used in later years, sometimes as a rotating plug and sometimes as a sliding one. Barnett also shows catalytic ignition and seems to have employed fine platinum wire or sponge for this purpose.

Beginning about 1835 a very persistent American worker, Dr. Alfred Drake of Philadelphia, began experiments which lasted for more than 20 years. During this time he developed an engine that is best known abroad, probably because more widely marketed in England and France by Lenoir. Instead of the jump spark as used by Lenoir he ignited by internally placed hot tubes, these tubes being kept hot by a flame blown into them by a pipe entering from the outside and igniting the mixture which surrounded them by their red heat. One of these engines exhibited at the Crystal Palace in New York in 1858 was seen by many people, who, later learning of the Lenoir, pronounced it the same as Drake's.

Another inventor whose patent descriptions give us much information and whose advertisements appeared in the magazines of that time, was Stuart Perry of New York, whose patents, Nos. 3597 of 1844 and 4800 of 1846, show what even to-day seem to be practical internal combustion engines. He used turpentine for fuel, but mentions that other liquid fuels were usable. The older patent described an air-cooled engine, whereas the later one shows water cooling.



Barnett Gas Engine

Double Acting Engine Tried

Perry's engine was double-acting, being built much as a steam engine. Its action was that of a two-cycle much like the Lenoir of later years, except that the air and vapor were forced into the working cylinder by pumps instead of being drawn in by the piston movement. The new charge was ignited by flame ignition when the piston had traveled about one-eighth of its stroke, which gave considerable length of stroke yet remaining for expansion and, therefore, must have been fairly economical; in fact, it much excelled Lenoir (years later) in this respect because Lenoir did not ignite his new charge until well toward the center of the piston movement.

Perry says that sliding or other valves may be used but he shows rotating cylindrical valves with ports cut in the sides thereof, like the Duryea of 1906 and the Darracq of 1907. His liquid fuel was vaporized by the heat of the cylinder and of the exhaust gas after the engine was started.

Of his air cooling, Perry said: "I prefer to inclose the cylinder and its immediate appendages in a case through which cold air may be blown by means of a rotary fan or other blowing apparatus which may be operated by the engine in any convenient manner." This air-jacket idea for the cylinder is still in use.

In his water-cooled engine he not only surrounded the cylinder with water, but lubricated the piston and inside of the cylinder with water, which both prevented wear and overheating.

In this engine Perry introduced platinum ignition, a form that received much attention from gas-engine inventors about that time. One of the most important features of his patent of 1846 "consists in the employment of a receiver containing condensed (compressed) atmospheric air for starting the engine, in combination with another receiver and with an air pump, . . . said pump being operated by the engine." Thus do we find both from Perry and from Cayley of 9 years earlier, that the self-starting of an air or gas engine was a matter worthy of their consideration. The starter idea is not new to the twentieth century, but is one more example of the grasp inventors had of the problem in 1840.

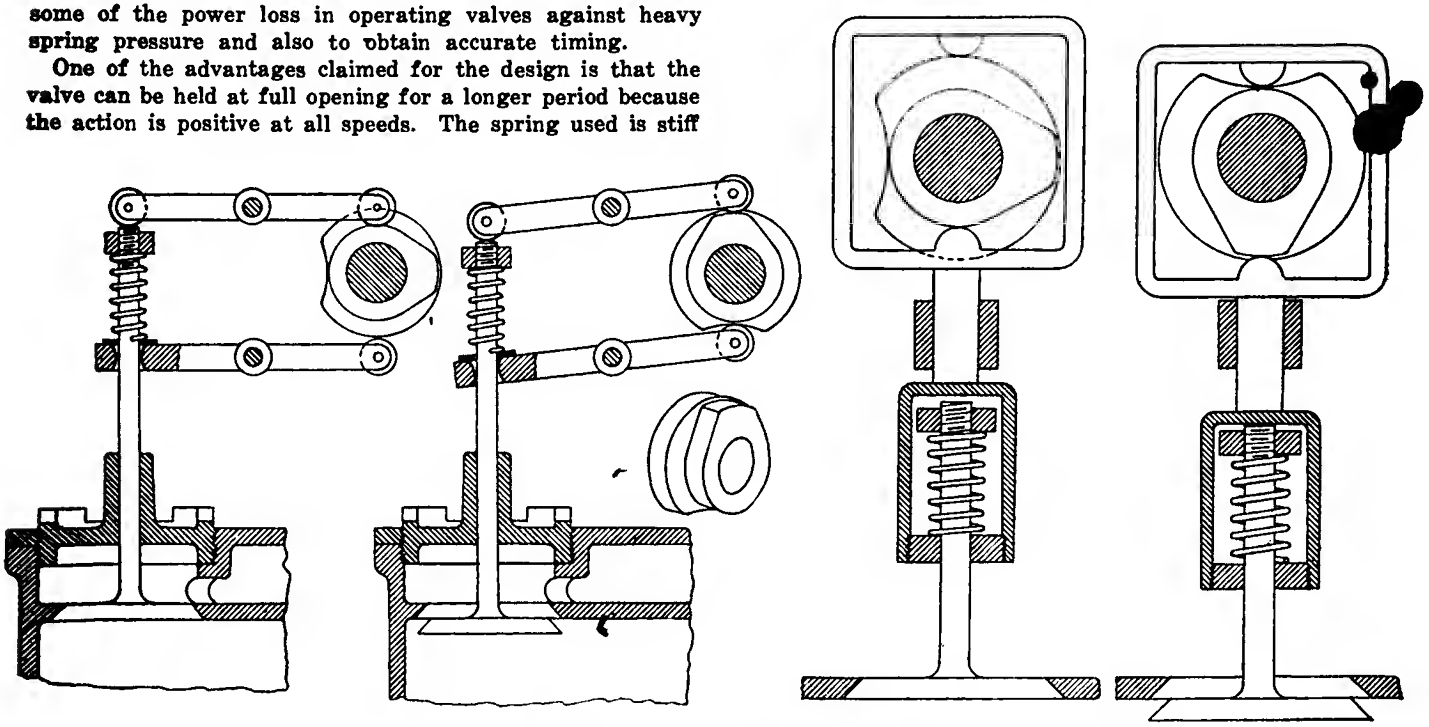
Start of Coil Ignition

Coincident with the work of Drake was the development of the step-up induction or double-coil now used in connection with all jump-spark ignitions. This coil is commonly termed a Ruhmkorff coil, because in February, 1852, the Emperor Napoleon of France offered a reward of 50,000 francs to the man who could produce the most important electric invention during the next 5 years, which period was extended later to a further 5 years. This award was finally given to H. D. Ruhmkorff, a Paris instrument maker, for inventing this coil. It was, however, first developed by Prof. Chas. G. Page of Washington, D. C., following the researches of Faraday, Joseph Henry and W. Sturgeon, about 1831. It should, therefore, more properly be termed Page's coil. As early as 1838 Professor Page and J. H. Abbott built some large induction coils, and in 1836 N. J. Callan described the jump or induction coil having a vibrator or interrupter. This coil was, therefore, well known in America before the award to Ruhmkorff, or its use in a gas engine by Lenoir.

Valve Action Designed to Reduce Power Loss

IN view of the recent controversies on valves and valve spring pressures, a design which was originated by F. F. MacVicar of Syracuse, N. Y., in 1907, is of interest. As the illustrations indicate, the action was designed to overcome some of the power loss in operating valves against heavy spring pressure and also to obtain accurate timing.

One of the advantages claimed for the design is that the valve can be held at full opening for a longer period because the action is positive at all speeds. The spring used is stiff enough to insure the cam acting on the valve, but is arranged to give only slightly when the valve regains its seat, thus preventing the closing cam from bottoming.



Methods of utilizing MacVicar valve mechanism with direct and finger following actions

Dodge Motor Assembly Progressive

System Follows Modern Method of Detail Building Up in Stages

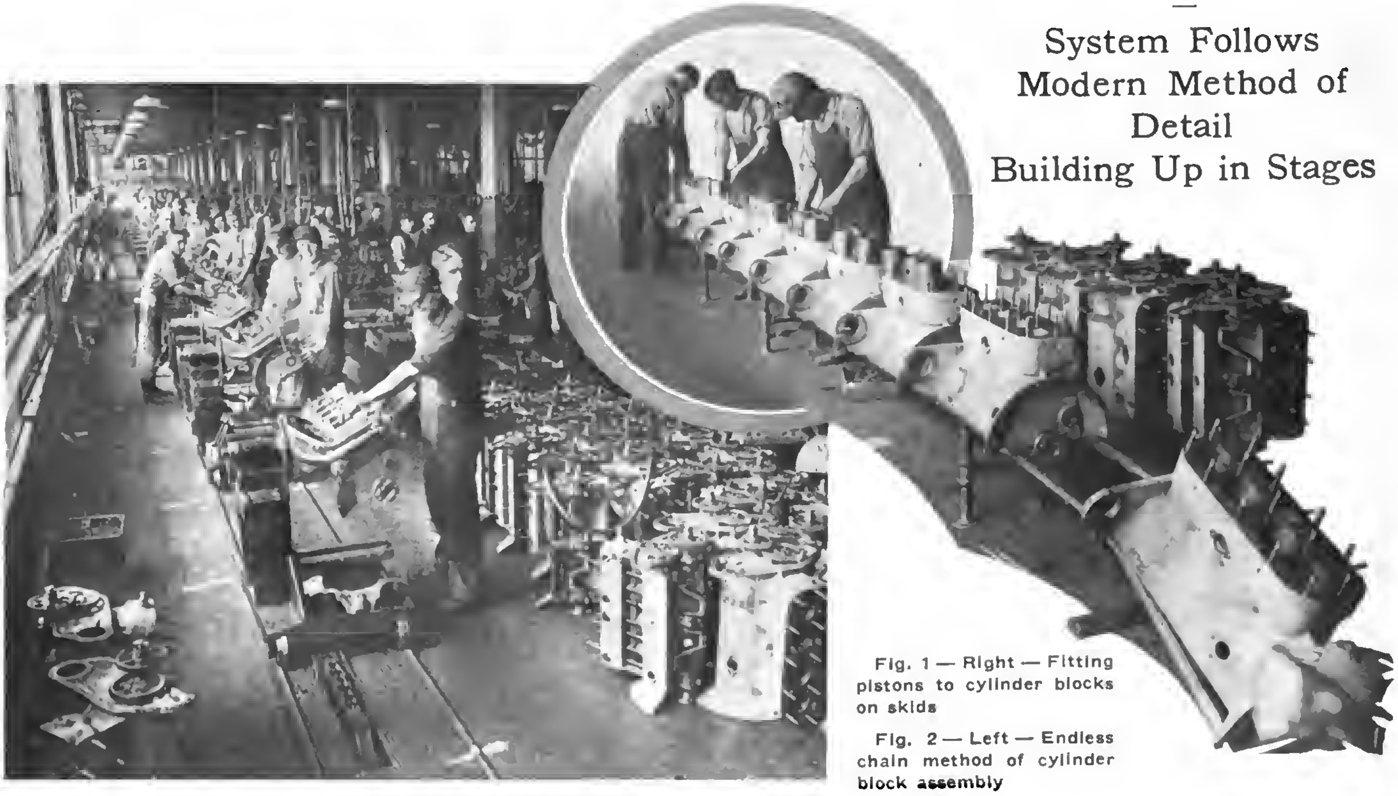


Fig. 1 — Right — Fitting pistons to cylinder blocks on skids

Fig. 2 — Left — Endless chain method of cylinder block assembly

THE two views here shown give some idea of the extensive manufacturing facilities now used by Dodge Bros., Detroit, Mich. They illustrate two phases of the progressive motor assembly department where over 400 motors are assembled daily.

Fig. 1 shows the cylinder blocks after the crankshaft and camshaft have been installed, and the crankshaft bearings properly fitted. The valves have been fitted and ground into their seats, each one being numbered, so that if they are removed at any time, they will be properly replaced. The cylinder blocks are slid onto skids so as to be in the most accessible position for fitting the pistons. The connecting-rods have already been fitted to the crankshaft which is in the cylinder block, and have been numbered properly, so that they can be reassembled in the motor when the proper sized pistons are attached to them.

Correct Balance Insured

Racks of pistons are placed conveniently beside the skids and so arranged that each bin contains pistons of exactly the same weight, so that for each cylinder block, pistons are taken from the same bin, thus insuring a proper balance of the reciprocating parts, as the connecting-rods are also matched in the same way. Each cylinder is then fitted individually, so that the clearance between the cylinders and the piston is exactly the thickness of a 0.003-in. ribbon feeler. The pistons are then stamped on the top to insure their being assembled in their proper places. After they have been fitted in the cylinder blocks the pistons are sent over to an assembly bench, where piston rings of the proper sizes are fitted to them and where the connecting-rods are attached to them and the wristpins locked in place.

With the assembly of the connecting-rod, wristpin and piston complete, all these parts which have been fitted separately for the cylinder block are ready to be installed in it as a unit. This is done after the cylinder block has been placed on the line of the universal assembling stands.

Fig. 2 shows the double line of the cylinder block assembly. Each block is clamped in place in one of the universal assembling stands, which run on tracks and are propelled by an endless chain. After the block has been clamped in place it can be turned over to any one of four positions.

On the universal assembling machine are placed a cylinder head, gearcase cover and piston and connecting-rod assemblies. The smaller units are arranged in bins along the tracks of the assembling line, where the different groups of workmen perform their particular tasks in turn.

The mechanics in the center foreground are installing the valve springs. The next group of men are about to install the piston and connecting-rod assembly, which has been previously fitted.

The third group is mounting and adjusting the starter generator, and connecting up its silent chain drive to the crankshaft sprocket. Similarly, all the way down the line, each group of men has its particular task to perform.

Each Operation Is Checked

Inspectors are stationed along the assembling lines so that each operation of the assembly is carefully checked up. Also each following inspector has an opportunity of seeing that nothing has slipped by the attention of the previous inspection. Thus, by the time the engine has been completed, an extremely thorough inspection of the cylinder block and its parts has been made. When the end of the cylinder block assembly line is reached, the completely assembled gearsets are brought up to the cylinders and bolted on. The power plant is then removed and conveyed upon a special truck to the block test, to be run in and tested under its own power. The universal assembling stand is then returned to the start of the line by a third chain and track.

ACCESSORIES

THE accompanying illustration shows the latest type Van indicator, a Van speedometer with an Elgin watch. This type of speedometer is named the Spedistemeter by its manufacturer. The speed and distance recording part of the instrument is identical with the regular type of Van speedometer, but the Elgin watch is incorporated in a rather unusual manner. The watch dial is set in the main dial of the instrument and connected by a shaft with the watch works in the back. These works are at the back of the instrument and can be removed by unscrewing a cap. The winder and reset, as illustrated, is operated from a watch stem in the same manner as the ordinary watch. The winder and reset can also be operated from a knurled button which projects through a collar directly under the watch dial.—Van Sicklen Co., Elgin, Ill.

Van Sicklen Spedistemeter including Elgin watch

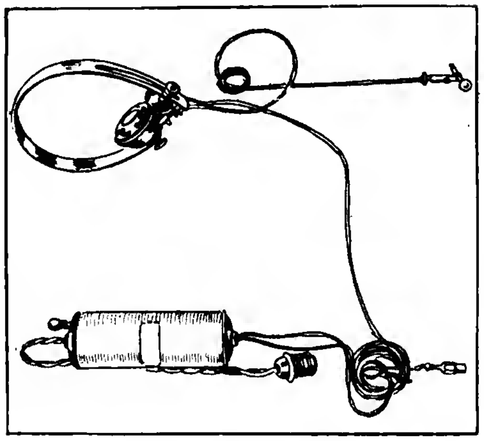
Evergood Channel Bumper

Under the name of Evergood a channel bar bumper has been brought out for the special purpose of taking care of the needs of Saxon four owners. The streamline design of the Saxon car is carried out, the bumper arms being curved in such a way as to seem to lengthen the wheelbase of the car.

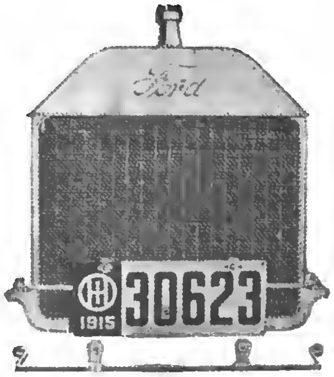
The bumper can be installed in 20 min. according to the manufacturer without the use of any drills or other implements outside the tools which are regularly in the repair kit. The arms are malleable castings and the springs which absorb the shocks are inclosed in tubes.

The round bar with nickel finish retails for $5.65; the combination black and nickel finish for $5.05. The channel bar bumper retails for $6.45. The diamond shape bumper with nickel retails for $7.05 and the combination black and nickel finish $6.45.—Emil Grossman Mfg. Co.

Evergood channel bumper for Saxon four



Boss electric circuit testing outfit



Tomarin license holder for Fords

Nodelay for Sealing Punctures

The Nodelay puncture-sealing compound is in the form of a liquid which is injected into the inner tube where it forms a coating over the inside and the balance of the compound remains in the tube as a liquid. The reason for this is that the compound does not adhere to itself but has a great affinity for rubber. It is claimed that, should a puncture occur, thus baring the rubber, the Nodelay liquid in the tube immediately forms a coating which seals the puncture. The compound is said to be unaffected by changes in temperature or weather conditions and to be soluble in water, so that, should any of it get on the clothes or any part of the car during the process of injection, it may be readily washed off. Injection can be done by any car owner or repairman. A 12-oz. bottle sells for $2, which is sufficient for a 30 by 3½ tire. A 20-oz. bottle or sufficient to treat a 37 by 5½ tire, sells for $3.—Nodelay Mfg. Co., Chicago, Ill.

Boss Circuit Tester

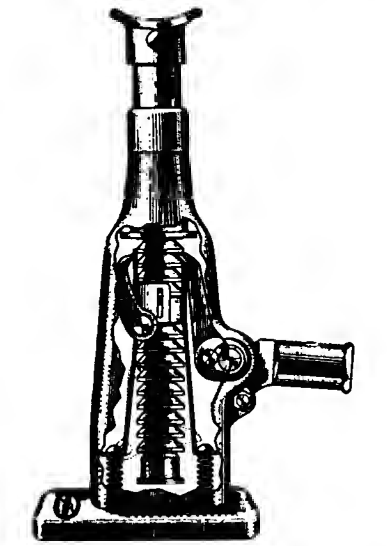
Any electrical circuit may be tested with this apparatus for grounds, short circuits or open circuits. A plug is screwed into any 110-volt alternating or direct current lamp socket, the telephone receiver placed on the head, where it is held by a band, and the terminal clips on the testing wires placed on the ends of the circuits to be tried out. A clear closed circuit is indicated by a clicking sound in the instrument. The amount of current consumed is so small that it will not affect the meter, the makers state, and the device cannot burn out. It sells for $12.75.—Maroa Mfg. Co., Maroa, Ill.

Tomarin License Holder

This license holder is a stout steel bar arranged to be bolted down by the radiator holding bolts of the Ford and extends across the lower part of the radiator. Sliding clamps are adjustable to any width of license plate. The bar adds to the stiffness of the radiator, the makers state, and holds the license plate where it does not interfere with the air coming through the radiator. The holder sells for 75 cents.—William Tomarin, Cincinnati, Ohio.

Peteler Jack

An ingenious feature of this jack, which operates by means of pawls on a stepped lifting bar, as shown in th[illegible] [illegible]llustration, is the automatic dr[illegible]ar. When the car is to be lowered, th[illegible]oper-



Peteler jack with automatic drop bar

ator presses the button on the side of the jack and it flies to reverse and the moment the weight of the car is removed the lifting bar drops automatically, rendering any pumping of the handle unnecessary. The jack is durably made, a large pressed steel shell forming a base reinforced by a wooden block. All parts of the device, in fact, are of pressed and hardened steel, including the pawls, while the lifting bar turns freely, distributing wear. The round swivel lifting bar allows greater freedom in placing the jack than is ordinarily possible. Another point is that the fulcrum is placed very low, giving greater upward play to the handle and preventing the operator's knuckles from striking the ground. For cars with low hung axles, a special head with a low step is provided. The jack is finished in black enamel and nickel. With the regular head it sells for $3.50 and with special drop head, for $4—Moreau & Pratt, Inc., New York City.

Roller-Smith Ammeters

Ammeters and voltmeters made under the name Roller-Smith are for dash installation, the case being of heavy brass with rubberoid finish which is said to be dust and moisture proof. The overall diameter of the instruments is 3⅛ in. and the depth 2⅝ in. Prices run from $5.30 to $7.—Roller-Smith Co., New York City.

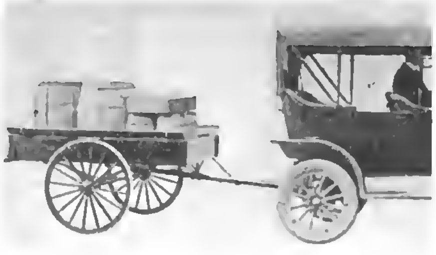
Lion Economy Trailer

This trailer has a capacity of 1000 lb. and is mounted on two wheels 34 in. in diameter with 1¼ in. solid rubber tires and running on Timken roller bearings. The axle is of 1¼-in. steel. The body is 42 by 72 in., of box form and has 8-in. panels and heavy hard wood sills, braced and ironed. Hard wood flare boards and a tailgate are fitted. A coupler is used fo[illegible]ttachment to the rear of the car, an[illegible]s is done without injuring the finish of the machine. The weight of the trailer is 375 lb.—Lion Buggy Co., Cincinnati, Ohio.

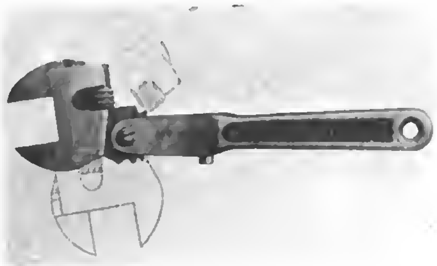
Kelco Batteries

This starting and lighting battery, in which an effort has been made to obtain greater efficiency by improving on the plate design, has been brought out under the name of Kelco. It is pointed out by the makers of this battery that while in charging the current is stored in all parts of the plate it is drawn out through but one point, and that is A at the corner of the plate. Accordingly, the makers have made the lines on metal ribs converge toward this corner, with the result that more metal is concentrated at the outlet. According to the theory of construction of the Kelco battery this puts the material where it is necessary. Other refinements of this battery include an incased handle to guard against corrosion and in a corrosion-proof terminal connector.—Storage Battery Appliance Co., Baltimore, Md.

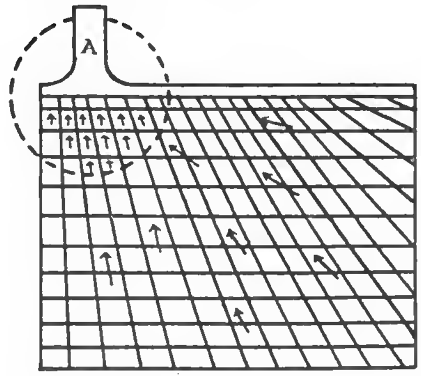
Roller-Smith ammeter for dash installation



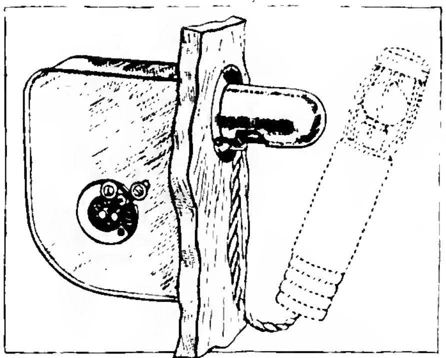
Lion 1000-lb. Economy trailer



Imperial angle wrench, showing some positions



Kelco battery plate, showing converging ribs



Cuno dash and inspection lamp

Imperial Angle Wrench

This is an end-opening, adjustable wrench, but the head, instead of being integral with the handle, is swiveled to it so that it can be turned through a very wide range and locked automatically in any one of eight different positions. A retaining ratchet, released by a button, holds any adjustment. The tool can be used as a ratchet wrench under certain conditions by pressing the button to permit the ratcheting action. The adjustable jaw will take any size up to 1¼ in. —Imperial Tool Co., Bloomington, Ill.

Cuno Dash Lamp and Timer

The Cuno dash lamp is combined with a trouble lamp, the handle of the latter disappearing into the dash together with a 15-ft. cord. The cord is automatically wound by a spring-operated reel in a sheet steel housing at the rear of the dash. Dash and trouble lamp combined sell for $4.25 without bulb; without bull's-eye for $4; and with reel and housing only $2.25.

The Cuno timer for Ford cars is made of steel enameled to prevent rusting, the fiber ring being of specially-heated, hard gray bone fiber, while the spring wire terminals guard against loose connections. The roller is carried in a slide, a large flat spring pressing it directly against the contacts. Price, $1.50.—Cuno Engineering Corp., Meriden, Conn.

Mansfield Top Dressing

This is called Never Leak Waterproof Dressing and is said to be impervious to water and dampness. No paint, varnish, shellac, linseed oil or asphaltum are used in its composition and it does not become stiff. A quart suffices for a roadster top and a half gallon for a five-passenger touring car. A pint sells for 60 cents, a quart $1, ½-gal. $1.75 and 1 gal. $3.—Mansfield Mfg. Corp., Syracuse, N. Y.

The Automobile is a consolidation of The Automobile (monthly) and the Motor Review (weekly), May, 1902, Dealer and Repairman (monthly), October, 1903, and the Automobile Magazine (monthly), July, 1907.

Body Measurements

CRITICISMS on body design, as made in a recent article in THE AUTOMOBILE, have touched a responsive chord, if the correspondence received on the subject can be any indication. These letters from representative engineers in the industry show that the belief is general that the driver, who, in an actual majority of instances, is the owner, is neglected. Some of the letters are published weekly in the Engineers' Forum department over the signatures of their senders.

Owners have been so gratified to secure efficient performance that they have allowed the feeling of delight in acceleration and economy to completely hide their feeling of resentment at being compelled to double up, jack-knife fashion, in driving, and it is time that a remedy be found for this trouble. To paraphrase Lincoln's famous epigram, the way matters stand at present: All of the people fit some of the cars, some of the people fit some of the cars, but most assuredly all of the people do not fit all of the cars, nor will they until cars are ordered like suits of clothing, by measurement, or a considerable amount of adjustability is offered.

However, it is possible to go a step further and say that some of the cars do not fit any of the people, because they have 5 and 6-in. passages through which anatomies must be squeezed; because the shifting of gears is accompanied by a stretch which almost brings the chin against the steering wheel or because the foot cannot be put upon the clutch pedal without a collision occurring between knee and steering column.

It must certainly be admitted that body design cannot be standardized nor will it be until some mythical date when all human beings are cast in the same mould. Therefore the best that manufacturers can do is to meet the requirements of the man of average stature in working out the stock design. Surely one who is fortunate enough to be of normal proportions ought to reap the benefit of being as nearly standardized as a human being can be, by feeling comfortable in a car designed to meet the needs of average proportions.

Earlier Winter Bodies

IT is to be hoped that the error of delivering winter automobile bodies to dealers in January and February instead of in September, October and November will not be repeated next fall. Many dealers who specified deliveries on closed jobs for last October found them starting to come through in December. The same manufacturers in a few cases want to force the dealer to show closed jobs at such shows as Minneapolis, Kansas City and Des Moines. Dealers in these cities can sell many closed cars but not in January or February. They must make their sales in October, November and December. Buyers of closed winter cars want immediate deliveries, particularly in cities west of the Mississippi where they have not learned to place their orders in May for October delivery. For dealers to sell and make deliveries in October, the cars should be on the floor Sept. 15. It is unfair of manufacturers not to give this service. The dealer deserves every assistance in this new field in Western cities, and those makers who are most considerate in this respect will receive greatest results.

Supply and Demand

IT is frequently difficult to distinguish between cause and effect, and just at present it is hard to determine to what extent the features of automobile design which are now the rule are effects of public demand or causes of it. Occasionally it is possible to be positive, as for instance, in the case of the eight-cylinder engine, for this undoubtedly was not demanded till the first American eight had made its bow to the public. After that moment the increase in the number of eights was certainly due to demand for them.

The automobile itself was not demanded, but rather it was forced upon a distinctly unwilling public in Europe and America alike. So with many features of present-day chassis they were created by engineers and, proving good, made their own demand. The moral of it is that features which prove good when thoroughly tested may be incorporated without much regard for convention. Nothing is a freak to-day, provided it does the work.

Traffic Situation Unchanged

Shipments in Feb. Expected Will Be Equal or Larger Than in Jan.

DETROIT, Feb. 21—Although there is no improvement in the general freight car situation so far as automobile shippers are concerned, it now looks as if the shipments of cars during February, which is a short month, will be equal to or even greater than were the January shipments, which totaled more than any previous month in the history of the motor car industry. No actual figures are yet available bearing on the number of automobiles thus far shipped this month, but from his daily reports, J. S. Marvin, traffic manager of the National Automobile Chamber of Commerce, is able to predict a total for February that may even outdo January's record.

Thus it is apparent that even though the manufacturers are handicapped by lack of railroad equipment and are not able to produce as many cars as they would like to on this account, they are doing better than ever before. There is no telling what the total production and shipments would be if the makers were able to ship all the cars they could make and for which they have immediate shipping orders. But when it is realized that there are in the whole country not over 60,000 automobile freight cars, it is really a wonder that it is possible to move the great number of machines that are moved each day. It speaks well for the efforts of the Chamber's traffic department, as well as the co-operation between the dealers receiving the cars, the railroads and the factories. The 10,000 new automobile freight cars for which the railroads placed orders some months ago, and which have been held up in manufacture due to lack of wheels and other steel parts, are now just beginning to put in their appearance. There are probably 200 to 300 of them already in service and more are coming right along. This will undoubtedly help the situation somewhat.

Some interesting sidelights on the present shortage of cars and the shipments of the previous year are given by the figures herewith which show the number of cars shipped each month during 1915. It will be seen that the January, 1915 total was outdone by 9685 carloads by January of this year, and even September, the palmiest month of 1915, was 864 below the present year's start. If proportionate increases are shown during this year it is difficult to see what the September, 1916, shipments will be. But if the shortage of cars continues, it is very likely that a much greater number of automobiles will be driven over the roads to their destinations from the factories than ever before.

Carload Shipments of Automobiles for each month of 1915

January	8,369
February	11,273
March	16,442
April	17,112
May	13,642
June	15,325
July	12,517
August	15,359
September	17,190
October	16,138
November	15,000
December	16,050
Total	174,417
Add shipments reported late and not distributed in their month	30,000
Total carloads 1915	204,417
Carloads shipped during January, 1916	18,054

Lewis R. Speare Dies

NEWTON, MASS., Feb. 23—Lewis R. Speare, former president of the A. A. A., died at his home here to-day after an illness of several weeks. He was taken to a hospital in January and operated upon for cirrhosis of the liver. Early in February he was brought home, and the physicians in charge stated that he could not recover, his death being a matter of strength.

Lewis Robinson Speare was born at Boston, Mass., June 6, 1861. He came of Puritan stock, having been traced back to 1647, while others were officers in the Revolution.

Mr. Speare was one of the first men in this country to take up motoring. Like everything else he became interested in he proved a dominant force. When the Massachusetts Automobile Club was formed he was one of its early members.

When the Bay State A. A. was formed in 1905, Mr. Speare was chosen president. He was re-elected and did much to get it started along a prosperous career. His activities as head of that organization brought him into the limelight, for he attended all the meetings of the American Automobile Association.

So when the organization needed a strong executive officer in 1909 he was chosen for the position. It was one of the best moves ever made by the association.

Cline Sun Factory Manager

ELKHART, IND., Feb. 17—B. J. Cline will join the Sun Motor Car Co., this city, in the capacity of factory and production manager. Mr. Cline has been identified with the automobile industry since 1898, at which time he assisted in building the first Pierce-Arrow car. Since then he has been with the E. R. Thomas Motor Car Co., Buffalo, N. Y., and later the Chalmers Motor Car Co., Detroit. He then joined the Chandler Motor Car Co., Cleveland, which was just being organized at the time.

The Sun company is now producing cars and will build ninety cars during the month of March.

Thomas To Drive Peugeot

Winner of 1914 Indianapolis Race Will Appear May 30 on Hoosier Track

PARIS, Feb. 17—*Special Cable*—Rene Thomas, winner of the 500-mile race on the Indianapolis Speedway in 1914, will drive a Peugeot in the 300-mile contest scheduled for the Hoosier track on May 30.

The above cable was received as THE AUTOMOBILE for Feb. 17 was on the press, so that it was possible to print it in only part of the edition.

Three Speedway Events for Tacoma

TACOMA, WASH., Feb. 17—Three series of racing events for this season are announced by the Tacoma Speedway Assn.—the first on Decoration Day, the second on July 4, and the third and largest racing event on the Pacific Coast this year, the Montamarathon Aug. 5.

Coupled with this announcement was the further one that F. G. Fisher has been elected president of the association to succeed Frank Allyn, resigned on account of ill health.

A number of short racing events featuring Northwest drivers will be staged on Decoration Day, and which will include a 100-mile event.

The Montamarathon on Aug. 5 will be for a prize of $10,000, with a bonus to the driver finishing the first 100 miles in the best time, and a like bonus to the man finishing the 200 miles in the best time. The race distance will be 300 miles instead of the former 250 miles.

Stutz Denies Rumors

INDIANAPOLIS, IND., Feb. 21—Rumors to the effect that Stutz cars may be seen in racing again, have been denied by the Stutz Motor Car Co. As stated by Mr. Stutz immediately after the Sheepshead Bay race in New York, his cars will not enter racing again until someone breaks or equals the world's records that the Stutz now holds.

$100,000 Corporation to Manufacture Electric Steel

MILWAUKEE, WIS. — Another large corporation to manufacture electric steel has been organized in Milwaukee. It is the Pelton Steel Co., capital stock $100,000, backed by several large bankers. An electric steel foundry will be established at once. The incorporators of the new concern are Fred Vogel, Jr., president, First National Bank; Gustav A. Reuss, vice-president, Marshall & Ilsley

Bank, and William H. Schuchardt, architect and capitalist. The foundry will have a 3-ton furnace. Several large steel foundries in Milwaukee have recently installed electric furnaces of large capacity, and Leo G. Smith, well-known steel founder, is building a large foundry, the Electric Steel Casting Co. of Milwaukee, capital stock $300,000, having been organized for this purpose. Several other founders are contemplating the purchase of electric furnaces.

Gridley Adams Leaves Stewart-Warner

CHICAGO, ILL., Feb. 21—Gridley Adams, advertising manager of the Stewart-Warner Speedometer Corp., is leaving that company to join the Macavoy Advertising Agency of Chicago, having bought an interest in that company. This agency has just secured the Jeffery account. With Mr. Adams will be several other men well known in the automobile field, especially the advertising field, namely, Frank Morse of the Mahin Agency; Berry Rockwell, late of the Mahin Agency and formerly advertising manager of the Maxwell-Briscoe Co., and with *Saturday Evening Post*, and G. N. Bryant, formerly with the Locomobile, Franklin and Moline-Knight.

Mr. Adams has been advertising manager of the Stewart-Warner Corp. for three years. He was formerly advertising manager of the Stoddard-Dayton Co., the United States Motor Co. of New York, and also the Aeolian Co., New York.

Lane Motor Truck Co. Formed

KALAMAZOO, MICH., Feb. 15—The Lane Motor Truck Co., is being formed with a capital stock of $25,000 to make a 1200 to 1500-lb. truck, with four styles of bodies, express, open flare board, stake body and stationary top flare body.

Maxwell to Sell Light Delivery

DETROIT, Feb. 22—The Maxwell Motor Co. is entering the light delivery car field. No special car will be made, but as the company believes that its standard chassis is well adapted for such a purpose, it will furnish the touring car chassis complete with cowl, instrument board and electrical equipment, but without body, at $565, or $90 less than the price of the standard touring car. Purchasers will receive a scale of dimensions which will enable any body builder to fit any type of body to the frame.

McCulla in Aeroplane Work

DETROIT, MICH., Feb. 19—William R. McCulla, who recently rejoined the engineering staff of the Packard Motor Car Co., has been given charge of the aeroplane motor division of the engineering department.

Aluminum Castings Increase Output

Castings Made Jan., 1916, Total 1,709,000 Lb. More than in Same Period of 1915

DETROIT, Feb. 22—While new customers are finding it difficult to obtain aluminum at present, those who have contracts with the casting companies are being well served. A year ago the Detroit plant of the Aluminum Castings Co. was about the right size to care for the demands made upon it, and to-day it is running at so high a pressure that extension in the early future is planned.

For the company's three plants at Detroit, Cleveland and Buffalo, the output of aluminum castings for January, 1916, exceeds that of January, 1915, by nearly 2,000,000 lb., and well over 90 per cent of the whole output goes to the automobile industry.

Cadillac to Use Aluminum Bodies

Of this increase about 125,000 lb. was cast in the form of permanent mold pistons, since no less than 123,000 of these were shipped during January, and they weigh a trifle over a pound apiece. During 1916 it is expected that well over 5000 aluminum cylinder castings will be made, and it is possible that this number will be doubled if the opening of the Southern plant of the American Aluminum Co. in April has the effect on the supply of metal that is anticipated.

The Detroit plant of the Aluminum Castings Co. has lately been supplying the Cadillac Co. with thin panel castings for their coupe body, and it is understood that all future Cadillac bodies will be of this material. At present the limousine will be built as before, but it is planned to use cast aluminum for this body also as soon as the casting plant is able to handle the business. The system of construction employed is exactly tht same as that which has now been used for many years by Pierce-Arrow.

States Motor Car Mfg. Co. Formed—Capital $600,000

KALAMAZOO, MICH., Feb. 17—The States Motor Car Mfg. Co., with a capital of $600,000, has been organized and will immediately begin manufacturing a line of eight and four-cylinder passenger cars and a four-cylinder truck. The plant formerly occupied by the Michigan Buggy Co. will be used.

The officers of the new company are: President, J. A. Ply; first vice-president, B. R. Barber; second vice-president, J. H. Johnson; and secretary and treasurer, Samuel Hoekstra.

The board of directors are as follows: J. A. Pyle, H. E. Johnson, B. R. Barber, G. B. Pulfer, Ira Cadwallader, W. B. Smith, and J. H. Johnson.

The output will be 10,000 cars a year. About 5000 cars will be built the first year.

The Light Car Axle Co. has leased 20,000 ft. of floorspace in the east building of the plant and has entered into contract with that company to supply all the front and rear axles for its cars.

Two New Studebaker Trucks

DETROIT, MICH., Feb. 23—*Special Telegram*—The Studebaker Corp. has announced two new models of commercial cars of 1-ton and ½-ton carrying capacities. The intention is to build 10,000 of them during 1916, and although the corporation has been building commercial cars of ½-ton capacity for several years, it has never attempted production of business vehicles on so large a scale before.

There are three body types fitted to each of the chassis. On the ½-ton are fitted a panel delivery body at $875, an open express design at $850 and a station and baggage wagon at $875. The 1-ton chassis carries either an open express body at $1,200, a stake body type at $1,250 or a sixteen-passenger bus at $1,400. Among the features are an electric starter and lights and a speedometer.

Overland Breaks February, 1915, Record

TOLEDO, OHIO, Feb. 18—On Feb. 11 the Willys-Overland Co. had broken its February, 1915, shipping record by over 500 cars. In other words, during the whole month of February, 1915, the company shipped 5627 Overland cars, while this year this total was shipped in less than half the month.

To Tax Canadian Ford $2,000,000

FORD, ONT., Feb. 19—According to officials of the Ford Motor Co. of Canada, Ltd., the share to be paid by the company to the Canadian government if the new war budget is adopted by parliament will be at least $2,000,000, of the total of $30,00,000, which, it is expected, the special budget will yield. The tax covers the period beginning Aug. 4, 1914, to Aug. 3, 1917, when it is anticipated the war will be at an end. All Canadian corporations are to contribute one-fourth of all their profits in excess of 7 per cent of the capital invested.

Reo Ships 2000 Cars in January

LANSING, MICH., Feb. 16—During January the Reo Motor Car Co., shipped close to 2000 cars as compared with 1000 in January, 1915. More cars were ready for shipment but there were not sufficient freight cars available. Production averages 125 cars a day and this will be kept up and possibly increased to next August.

Pennsylvania S. A. E. Section Completes Organization—Hears First Paper

Officers Elected and Constitution Adopted—A. M. Dean Gives Views on V Motor—Lively Discussion of Paper—Minimum Cylinder Bore 2⅝ in.

PHILADELPHIA, PA., Feb. 16—The organization meeting of the Pennsylvania Section of the Society of Automobile Engineers was held here to-night at the Engineers' Club. The first action taken by the new section after it had been voted that a permanent organization be made, was to elect the temporary chairman, E. S. Foljambe, the temporary secretary, B. B. Bachman, and T. Y. Olsen, temporary treasurer as permanent officers to serve until the end of the administration year, Oct. 1. In addition, W. M. Newkirk was elected vice-chairman and W. H. Palmer, Jr., as held-over treasurer. This is in accordance with the constitution and by-laws as recommended by the council of the S. A. E. and which were also adopted by the Pennsylvania section. The section is affiliated with the Engineers' Club.

Paper on Eights and Twelves

A. M. Dean, engineer of the Ferro Machine & Foundry Co., read a paper on the development of the eight and twelve-cylinder V engine in which he particularly alluded to the development of his concern and outlined the considerations back of this development. In opening his paper he referred to the typical American as compared with the typical European design, stating that the American motor carries the valves in the head while European practice favors the L type, the American motor uses individual cams while the European employs the same cam for opposite cylinders. Another point of difference is in the unit crankcase on American motors while foreign practice inclines toward the employment of a separate cast aluminum crankcase.

Taking up the motor part by part, Mr. Dean first dwelt on the development of the overhead valve construction, showing how the advantages of good combustion chamber shape had been maintained while the objections of large and heavy parts which tended to become noisy had been eliminated. Speaking of the use of the offset rocker, he showed its great advantage in the high-speed motor because it allows advantageous cam shape and at the same time gives quick opening of the valves with a minimum amount of travel of the parts. As an example of the successful use of the offset rocker, the number of years of satisfactory performance of the Franklin valve system was cited by Mr. Dean. Throughout the entire consideration of the valve question, Mr. Dean brought out the fact that the high speeds at which motors are now operated have thrown into position of relative importance the details which were formerly regarded as being unimportant.

A good example of careful detail as brought out in the paper is in the threaded pin adjustment for valve clearance. This governs the position of the pivot point of the rocker arm and has the great advantage that the adjustment parts are stationary, permitting adjustment of the clearances while the motor is running. Another detail which is of relatively great importance, is in the design of the connecting-rod bearings. The rods are so arranged that the bearing split is horizontal, and the reason for this is found in the method of firing across the blocks giving a resultant which makes it necessary in order to secure the best distribution of materials and stresses that the division of the bearing be in a horizontal plane.

Good Lubrication Practice

Taking up the question of oiling, Mr. Dean again contrasted European practice with best American practice. He said that a great many engineers in this country had blindly followed the DeDion system of having high pressures with a short registering interval between the crankshaft opening and the oil lead in the main bearing. He stated that he had found it better practice to use lower pressures for the oil with a longer register in order to feed the oil in proportion to the bearing loads.

A motor operates at its maximum efficiency, according to Mr. Dean, when the jacket temperature is at about 170 deg. In the experiments carried out by the Ferro company with the overhead type of V motor, the author stated that the waterjacket temperature never went over 200 deg. and rarely reached that point except under the most adverse circumstances. In laying out the waterjacket it was pointed out that the water passage should run between adjacent cylinders leaving no blocks of uncooled metal in the casting.

As regards balance, the system used by Mr. Dean is to apply a counterweighting system in which each throw or unit is considered separately. For the eight-cylinder motor this means a four counter-weight balancing arrangement, and for the twelve-cylinder motor an eight-weight arrangement. The added weight to a crankshaft due to this system, he said, ran to about 34 lb., giving a total weight for the shaft of 84 lb., but he then went on to show that the evils which may arise from unchecked centrifugal force were far more serious than added weight to the crankshaft, and the use of the counterbalancing system is fully justified by results.

Fields of Eights and Twelves

Coming to the respective fields of the eight and twelve, Mr. Dean gave an answer as to where the twelve took up the work and where the eight left off. He stated that the minimum diameter for a cylinder should be 2⅝ in. Below that there is trouble due to leakage past the rings and difficulty in securing good piston fits. Not only these conditions arise, but poor thermal efficiency also results from such small diameters. This statement Mr. Dean checks up with the experiences abroad which have gone to show that 75 mm. is the limit for efficient motors. Even taking this bore as the limit, he showed that the smallest twelve is still a large motor. Mr. Dean went on to state that the unbalanced forces in an eight are 1.4 times as large as those in a four, and this naturally immediately limits the size of the eight. With the small bore and light parts the vibrations are so cut down that they do not become serious until the upper limits for eight-cylinder size are reached. This upper limit he sets at 3¼ in. with a stroke bore ratio of 1.4. This gives a piston displacement of just under 300 cu. in. The upper limit for the twelve is only the limit of the chassis, and the lower limit would be about 250 cu. in. Therefore, the field of the eights in the author's opinion ranges from 160 to 300 cu. in. and of the twelves from 250 cu. in. up.

In discussing the paper, B. B. Bachman, engineer of the Autocar Co., asked if difficulties are not found in the block cast motors if the waterjackets are not extended far enough below the piston travel. Mr. Bachman pointed out that the juncture of the waterjacket with cylinder wall created a virtual ring of metal around the cylinder which restricts its expansion at that point because of the amount of unheated metal. To this Mr. Dean replied that such a ring of metal exists and if it is not carefully placed so that the jacket is below the piston travel seizing troubles are sure to be encountered. For this reason it is the practice of the Ferro company to always extend the waterjacket well below the piston travel.

J. E. Schipper discussed the comparative merits of the side-by-side and V rod, stating that although the bearing area in the forked rod is greater than that in the side-by-side design, the advantage of the latter as regards repair work is so marked that it is well worth while to use it if life is not sacrificed. Another point brought up by Mr. Schipper is that in starting the motor with the aluminum pistons since the clearances run up as high as 0.006 in. unless special provision is made, oil is sure to accumulate in the combustion chamber during the first few strokes. Mr. Dean answered these comments by stating that his concern, while usually building the forked type of rod, has had some motors on the road with the side-by-side installation for about a year, and found no difference in bearing life which so far could be indicated. In regard to the oiling trouble, he stated that this is overcome by the use of longer pistons and by special rings which take up the clearance and prevent excess leakage. The slight slap of the aluminum piston, however, can be noticed for the first few moments of operation.

Those present at the meeting included E. S. Foljambe; W. E. Haupt, Engineer Haupt Auto Patent Co.; W. M. Newkirk, mechanical engineer William & Harvey Rowland; T. Y. Olsen, Tinius Y. Olsen Testing Machine Co.; Albert Sutthill, chief engineer James Boyd & Bros.; Russell Hoopes, Supt. Hoopes Bros.; J. E. Chalfant; P. J. Flaherty, general manager American Car & Ship Hardware Mfg. Co.; H. R. McMahon, president of the Standard Steel Spring Co.; J. E. Schipper, technical editor THE AUTOMOBILE; W. H. Palmer, Jr., engineer Electric Storage Battery Co.; B. B. Bachman, engineer Autocar Co. Several in attendance were not members of the S. A. E.

Goodrich Surplus $10,305,679

Equal to 17.17 on Common—Net Sales Equal $55,416,866.55—32½% Gain

NEW YORK CITY, Feb. 19—The B. F. Goodrich Co. in 1915 showed a surplus of $10,305,679, equal to 17.17 per cent on the $60,000,000 common stock, as against $3,371,927 in 1914, or equal to 5.62 per cent.

Net sales for the year ended Dec. 31, 1915, aggregated $55,416,866.55, as compared with $41,764,008.66 for 1914, representing a gain of 32½ per cent. Net profits amounted to $12,265,679, compared with $5,440,427 in 1914.

The directors of the company voted, subject to the approval of the shareholders, to retire 7000 shares of the preferred stock. This is in accordance with the provision of the company's charter, which provides for the retirement of a minimum of 9000 shares of the preferred stock each year, beginning with July, 1914. As last year the company retired 2000 shares in excess of the charter requirements, it was necessary to retire only 7000 shares additional prior to July, 1916.

The company has added to its plant account during the year 1915 extensions and equipment costing $1,332,146.70, and still further additions are now under way.

From the surplus at Dec. 31, 1915, the directors voted to set aside $1,700,000 to increase the reserve for contingencies from $300,000 to $2,000,000, together with a sum of $100,000, as an initial amount, for a pension fund. The directors were led to appropriate this amount for contingencies on account of the general unsettled conditions existing throughout the world and the consequent desire to reinforce the fund available to meet unfavorable conditions should they arise.

The income account in detail is given in tabular form on this page.

	1915	1914	1913
Net sales	$55,416,866	$41,764,008	$39,509,347
Manufacturing, selling and general administration expenses	42,825,908	36,189,642	36,451,234
Net profit from operation	$12,590,957	$5,574,367	$3,058,113
Miscellaneous income	467,690	562,930	491,317
Total income	$13,058,648	$6,137,297	$3,549,429
Depreciation	734,544	573,616	541,358

Belgian Trade Leaders Indicted

PARIS, Feb. 1—Van den Plass, the world-famed Belgian bodybuilders, Captain Masui, for many years a leading automobile agent in London, and two other Belgian subjects, are now before the military court at Calais on a charge of defrauding the Belgian Government. It is declared that the sum involved is $10,000,000 to $12,000,000, the case being so serious that the Belgian Government is acting as civil prosecutor. Soon after war broke out, the men involved were sent to England to make purchases of automobiles for the Belgian army. A little later they obtained other purchasing commissions for all kinds of material required by the Belgian army. It is declared that they have obtained enormous fraudulent profits on these transactions, and on an inquiry being opened a few days ago it was discovered that they had made cash deposits in a London bank totalling $340,000.

Before the war Van den Plass was at the head of an automobile body factory at Brussels, where he employed 4000 work people. He was generally recognized as one of the most artistic and best bodybuilders in the world.

Buick Prices Advanced $35

NEW YORK CITY, Feb. 21—An advance of $35 in the price of the Buick light sixes has been made by the Buick Motor Co., Flint, Mich. The roadster will sell for $985 and the touring cars for $1,020 f.o.b. factory.

The light six will carry 34 by 4-in. wheels and tires, instead of 32 by 4-in. as originally on this series. These prices and models will run through the entire 1916 season.

Anderson Joins Master Carbureter

DETROIT, Feb. 21—Raymond M. Anderson, for five years chief engineer of the Stromberg Motor Devices Co., Chicago, and later research engineer of the J. I. Case T. M. Co., Racine, Wis., has joined the forces of the Master Carbureter Corp., this city, in the capacity of chief engineer.

Year's Exports Show Huge Increase—Total for 1916 $111,180,139

Great Britain Much the Heaviest Buyer—French Imports Large—Value of Canadian Imports Drops Though Number of Cars Increases

WASHINGTON, D. C., Feb. 21—The wonderful showing the United States has made in the exportation of automobiles during the last calendar year, as compared with the corresponding period of 1914, is shown in great detail in the figures issued to-day by the Department of Commerce. During the first mentioned period there were 22,082 commercial cars, valued at $59,834,246; 41,869 pleasure cars, valued at $35,045,492, and parts, not including engines and tires, valued at $16,300,401, shipped to various portions of the globe. Of course, a large proportion of these went to the warring countries in Europe.

For the same period of 1914, the figures show that 3430 commercial cars, valued at $8,985,756; 22,335 pleasure cars, valued at $19,521,708, and parts, not including engines and tires, valued at $5,664,104, were exported.

The exports for December last amounted to 1664 commercial cars, valued at $3,920,533; 3664 pleasure cars, valued at $2,710,758, and parts, not including engines and tires, valued at $1,791,805.

These are the figures for the same month of 1914: Commercial cars, 1279, valued at $3,387,729; pleasure cars, 1297, valued at $998,698; parts, not including engines and tires, $1,791,805.

The figures show that the United Kingdom was our best customer in both 1914 and 1915, the purchases of that country increasing from 6799 cars, valued at $6,891,511, in 1914, to 24,355 cars, valued at $35,055,097, in 1915. The December purchases increased from 850 cars, valued at $1,097,007, in 1914, to 1366 cars, valued at $1,969,048, in 1915.

France a Heavy Buyer

The war has likewise made France a good buyer of American cars, no less than 6304, valued at $15,922,313, being shipped there during the calendar year 1915, as against 2816 cars, valued at $5,099,452, imported in 1914. However, during the monthly period the shipments dropped from 969 cars, valued at $2,588,622, in December, 1914, to 423 cars, valued at $1,034,581, in December last.

We shipped 235 cars to Italy in 1914, the value of which was $160,058. In 1915 the number was 257 and the value $160,368. There were no shipments of automobiles to that country in December, 1914, but in December last 31 cars, valued at $15,494, were exported there.

Germany Cut Off

Our export trade in automobiles with Germany amounted to 1063 cars, valued at $799,552, in 1914, while in 1915 the number was only 4 and the value $2,800. There were no shipments to that country either in December, 1914, or in December last.

Under the heading, "Other Europe," a large increase in exports is indicated, no less than 8630 cars, valued at $22,330,357, being exported to those unnamed countries in 1915, as against 2785 cars, valued at $3,411,100, exported in 1914. During the December period these shipments increased from 27 cars, valued at $29,436, in 1914, to 608 cars, valued at $1,272,807, in 1915.

While more cars were shipped to Canada in 1915 than in 1914, the value was less. In 1914 the number was 4214 and the value $5,347,547, while in 1915 the number was 5796, while the value was $4,622,931. In December, 1914, 128 cars, valued at $189,466, were shipped across the border, while in December last the number was 348 and the value $259,110.

The West Indies and Bermuda are developing into good customers for American cars, the exports showing an increase from 646 cars, valued at $525,062, in 1914, to $1,877,680 in 1915. South America's imports of American cars likewise increased from 1149 cars, valued at $863,360, in 1914 to 3537 cars, valued at $1,862,326 in 1915.

The shipments of cars to British Oceania increased from 3475 cars, valued at $2,955,825, in 1914, to 4818 cars, valued at $4,075,299, while the exports to Asia and other Oceania increased from 1454 cars, valued at $1,425,656, to 4319 cars, valued at $6,278,813, during the same period.

Ford Will Not Build at Wichita

KANSAS CITY, MO., Feb. 19—The Ford Motor Co. will not open an assembling plant at Wichita, Kan., as had been announced by the officials of the plant here. That decision came as the result of grants made to the Ford company by the city council that will permit further enlargement of the plant here. Between 7000 and 10,000 cars a year would have been assembled at Wichita if the plant had been built.

Bimel Automobile Co. Now

SIDNEY OHIO, Feb. 21—The Bimel Buggy Co. has reincorporated as the Bimel Automobile Co., increasing its capital to $500,000. The buggy company was established in 1844. The present company took charge of the plant in this city in 1905.

The company has closed out its vehicle line and will concentrate on four- and six-cylinder cars. The four has been built during the last year for $585.

The latest development is a six-cylinder model with a motor, 3⅛ by 5 in., selling at $1,000 and up. This car will be ready for delivery by April 1.

White Resigns from Lozier

NEW YORK CITY, Feb. 21—W. McK. White has resigned as sales manager of the Lozier Motor Co., Detroit, Mich., to form the company of Holden and White, 320 New York Life Building, Chicago. This company will act as general sales agent for four manufacturers of railroad supplies.

S. A. E. Summer Trip Four Days on Lakes

Start Monday June 1—Noronic Again Chartered—Many New Members Admitted

DETROIT, Feb. 16—At the regular monthly meeting of the council of the Society of Automobile Engineers, the date of the annual summer session was arranged for and will be a four-day one beginning Monday, June 12, and ending Friday evening, June 16. The session will be held on the Great Lakes on the Steamer Noronic. Accommodation for over 500 members will be provided. There will be the usual professional sessions, work of Standards committees, and in addition the trip through Lake Huron and Georgian Bay will afford good opportunity for fishing, picknicking and various out-door sports.

The following applications for membership were approved: Charles R. Bissel, New York City; David W. Burke, Pittsburgh, Pa.; Andrew K. Brumbaugh, Ardmore, Pa.; Richard A. Leavell, Ames, Iowa; Harrold S. Edwards, Madison, Wis.; Frederick S. Elett, Elmira, N. Y.; Hugh M. Harris, Detroit, Mich.; Wm. A. McCosh, Indianapolis, Ind.; Nicolas G. Koutznetzoff, Petrograd, Russia; Eugene J. Ney, New York City; Glen Muffly, Chicago, Ill.; John F. Wade, Bristol, Conn.; W. J. Murray, Newark, N. J.; R. E. Plimpton, New York City; C. A. Obermaier, Harvey, Ill.; Ed. H. Rembe, Cleveland, O.; Westcott J. Smith, Detroit, Mich.; Alfred T. Sturt, New York City; O. P. Stehn, Cleveland, O.; Edw. W. Thurston, New York City; W. R. Vogeler, New York City, and R. L. Heberling, Philadelphia, Pa.

It was decided to move the office of Recorder of the Standards Committee from Detroit, where it has been located since its inception, six months ago, to New York where it will be located in the general offices of the society, 29 West Thirty-ninth Street.

The complete personnel of all of the members of the various Standards committees was passed upon and other routine work carried out.

Testing Symposium for Metropolitan S. A. E.

NEW YORK CITY, Feb. 19—At the meeting of the Metropolitan Section of the Society of Automobile Engineers to be held in this city at the Automobile Club of America next Thursday, Feb. 24, at 8.15 p. m., there will be a symposium on motor testing. The topic will be introduced by Peter Payne Dean, M. A. I. E. E., with a paper entitled "Late Developments in Chassis and Motor Testing." Mr. C. F. Scott, engineer of the Sprague Electric Works, will discuss the topic and the laboratory side of the matter will be presented by Herbert Chase and Ferdinand Jehle of the engineering department of the Automobile Club of America.

This is the last meeting of the fiscal year of the Metropolitan Section and the report of the secretary and treasurer will also be presented. The incoming officers are Leonard Kebler, president of the Ward Leonard Electric Co., chairman; Harry Tipper, advertising manager the Texas Co., secretary, and H. G. McComb, engineer the General Vehicle Co., treasurer. The held-over officers will be R. McA. Lloyd, consulting engineer and J. Edward Schipper, technical editor THE AUTOMOBILE.

Stewart Body Plant to Be Doubled

FLINT, MICH., Feb. 19—The plant of the W. F. Stewart Co., body manufacturer, will be practically doubled, according to an announcement made by president S. S. Stewart. The plant consists of half a dozen large factory buildings and some minor buildings. Additional floors will be put up on some, while in other instances additions to the buildings will be erected. A large number of dry kilns will be added, which will add at least 36,000 ft. of lumber per day to the plant's capacity. About 15,000 sq. ft. of floor space will be added to the sheet metal department.

Lighter Acme Truck

DETROIT, MICH., Feb. 17—The Cadillac Auto Truck Co., Cadillac, Mich. will commence deliveries May 1 on its new 1-ton model. The new truck will resemble the 2-tonner in appearance and will be priced at $1,290. It has a 3½ by 5 Continental engine incorporated in a unit with a Warner dry-disk clutch and three-speed gearset, driving through a Timken worm-driven rear axle. It will have a Rayfield carbureter, Eisemann fixed-spark single ignition and a Pierce governor set at 22 m.p.h. maximum.

Briscoe to Absorb Jackson Motor Shaft Co. July 1

JACKSON, MICH., Feb. 18—A deal has been closed between the Jackson Motor Shaft Co., and the Briscoe Motor Co., whereby the former concern will become part of the Briscoe organization beginning July 1, the Briscoe interests having purchased the plant and business.

The Jackson Motor Shaft Co. succeeded to the Hastings Motor Shaft Co. several years ago. There are now 180 men on the company's pay roll.

Leight C. Bloomfield, who has been with the company since it succeeded the Hastings company, will remain as general manager.

Elgin Plans Week of Racing

Promoters Hope for Vanderbilt, Grand Prize and Two Elgin Classics

ELGIN, ILL., Feb. 19—Elgin has been given the opportunity of becoming the exclusive road racing center of the world for 1916. The four highway classics of America, the Vanderbilt Cup, Grand Prize, Elgin National trophy and the Chicago Automobile Club trophy, may be run over the Elgin course next August. Promoters of the Elgin road races, the Elgin Motor Club and the Chicago Automobile Club, have determined to land the speed carnival for Elgin. Their action followed the announcement of the Motor Cups Holding corporation, that no sanctions of the Vanderbilt and Grand Prize will be issued for speedways. To secure the classic it will be necessary for Elgin to raise $15,000. This will probably be done by selling 1500 tickets at $10 each, entitling the holder to admittance to all four events, Elgin guaranteeing that one-half will be sold.

Want 8-Day Meet

Although Elgin enthusiasts believe that the Classic could be held here in four days, Chicago promoters favor eight days, commencing on Saturday and ending on the following Saturday. The plan of the Chicago enthusiasts is to have an entire week of racing, opening with the Vanderbilt Cup and closing with the Grand Prize. The former will be a 300-mile event and the latter 500 miles. It is proposed that the contests for the Chicago Cup and Elgin National trophy, be staged on Tuesday and Thursday, respectively and the distance of each be cut to 200 miles. The prize money is to be distributed as follows: $3,000 for first; $1,500 for second; $900 for third and $600 for fourth. This is $1,000 less than was offered for the Grand Prize and Vanderbilt Cup at San Francisco last year but double the amount hung for either of the Elgin events last year. The cost for promoting the classics would be about $40,000 or an average of $10,000 for each.

Premier Engineers in Detroit

DETROIT, MICH., Feb. 21—The Premier Motor Corp., Indianapolis, will maintain part of its engineering department in Detroit, where the designing of the new Premier models is to be made. Quarters have been opened in the Kresge Building and E. G. Gunn and C. S. Crawford, who, with J. L. Yarcan form the engineering board of the corporation, will be located in Detroit most of their time.

Colorado Winter Automobile Sales Are Double Those of a Year Ago

Prospects for 1916 Sales are Regarded Excellent by Dealers Who Anticipate Demands for at Least 12,000 Cars—Road Development Will Help

DENVER, COL., Feb. 18—Denver's automobile row winter business averages about double that of last year, and its prospects are declared the best yet. Figured on the basis of the last three months, sales increases ranging from 30 to 500 per cent over the corresponding period a year ago are reported by established dealers, while a doubling or even trebling of last winter's business is shown in many cases.

Greatest Growth in East

Naturally, this substantial showing in growth of sales is most pronounced in the eastern half of Colorado, where moderate snowfall and pleasant weather in general have encouraged winter motoring and winter buying. But the gratifying prospects for total 1916 business are in evidence throughout the State, and also through Wyoming, Utah, New Mexico and all other Rocky Mountain territory supplied by Denver distributors. Sub-dealers throughout the district are backing up their claims concerning the favorable outlook by placing orders for cars in goodly numbers and urging prompt delivery to take care of demands likely to come in a rush with the first settled weather for spring motoring.

Colorado's State license law for motor vehicles went into effect in July, 1913, and every year has shown such a surprising increase in car registration that the Secretary of State has found it necessary to purchase several hundred more license tags than originally ordered upon an estimate allowing for a liberal increase. The 1914 record exceeded that of 1913 by nearly 5000 cars, and 1915 showed an additional increase of nearly 10,000. Colorado dealers are unanimous in supporting Secretary of State Ramer's estimate of another 12,000-car growth in 1916, while many of them declare that 20,000 would be a safe estimate. The exact figures for the three years under the State registration law are as follows:

1913	13,624
1914	18,433
1915	28,254

Twenty-six Inhabitants per Car

This is regarded as an exceptionally good showing for a State having a total population of only a little over 800,000—scarcely a third as many people as are claimed by the City of Chicago alone. Besides, a large portion of the State is mountainous, motor roads are hard to build, and in some sections it would be necessary to travel many miles to find enough citizens to fill a seven-passenger car.

Already three established transcontinental highways cross the main range of the Rockies in Colorado, and three more roads to connect important scenic and industrial sections will be completed across the Continental Divide within the next year or two, one of these traversing almost the entire length of the State. State Highway Commissioner Ehrhart says that more than $2,000,000 will be used for road improvements this year from the State and county funds.

The mining industry of the State shows a gradual growth, which is considered far better than the frequent "booms" of those days when fortunes were made in a day by a rich strike of high-grade ore—and frequently lost in a night through attempts to double them by tackling the other fellow's gambling game. And yet even the last few months have developed a near approach to a real "boom" in Boulder County's world-famed tungsten district 50 miles from Denver, through new strikes of remarkably rich ore, combined with the rapid jumps in the price of tungsten due to the demand for this product for automobile and tool steel purposes.

Adds New Industries

While thinly settled, mountainous, and not extensively an agricultural State, Colorado has also been making rapid progress in this direction during the last few years, and has already won recognition in national markets for fruits, sugar beets, potatoes, alfalfa and other crops. The State has been especially fortunate the last two years in having an abundance of irrigation water in all districts, along with an unusual amount of rainfall sufficient to insure favorable crop returns in the dry-farming sections. Deep plowing and other modern, scientific methods are also making for rapid development of this non-irrigated territory, where thousands of acres still remain to be settled.

An example of Colorado's good fortune in farm returns last year was the excellent potato crop, which brought an unusually good price on account of a marked shortage in other parts of the country.

Stock raising is still a flourishing industry in Colorado and adjacent States, with prevailing high prices, and the last two years have afforded favorable conditions for both summer grazing and winter feeding.

Fully one-half of Colorado's more than 28,000 cars now belong in cities and towns, nearly a third of the total being in Denver alone; but the proportion owned by farmers and stockmen is rapidly increasing, and this class of trade promises to make a big showing within the next decade. Many of these people bought cars at the time of the fall show held by the Automobile Trades' Association of Colorado last October, hundreds more studied new models at that exhibit, and the stimulus given the motor industry throughout this territory by that event is still being felt.

The use of tractors in this district has only begun, and the tractor business is still being handled by implement dealers. Where tractors can be afforded, however, and are being tried out in the cultivation of a big acreage, they are a big success. The tractor method is particularly valuable for deep plowing in the dry-farming sections, where the farmers are able to make the necessary outlay to buy the required equipment.

National Parks an Asset

Another aid to the automobile industry in this region is the national part movement, with the recent establishing of the Rocky Mountain National Park, a wild, scenic tract of 360 square miles of mountain playground 100 miles northwest of Denver, the opening of the Yellowstone National Park to motor cars, the proposed government road connecting these and other national parks in the West, and other enterprises for developing scenic resources, building better and more attractive highways and in general promoting motor travel. One result of this increased travel is the attracting of more and more capital from the outside to help develop the resources of the mountain States, which, in turn, builds up general business and broadens the smile of the dealer.

To take care of their growing business in the Rocky Mountain district, the Ford Co. built an assembling plant in Denver two years ago to supply Colorado, Wyoming, Utah and New Mexico. A practical indication of how the business of this one concern has increased here since that time is furnished by the fact that ground will be broken within a week for the erection of an additional building to double the new plant's present capacity of between sixty and seventy cars a day. This will also mean a considerable increase in the present force of 300 men employed, and will thus contribute a substantial increase to general business in Denver.

During the last three months, the Ford increase over last year has been about 300 per cent here in Denver, and 200 per cent throughout the rest of the territory.

The Hudson, Dodge, Oakland, Dort, King, Grant, Saxon, Buick, Chevrolet, Overland, Studebaker, Metz, Maxwell, Haynes, Pierce, Packard, Paige, Abbott, Chalmers, Hupmobile and other established makes also show sales increases running to 100 and 200 per cent over a year ago, while the Scripps-Booth, Enger, H. A. L. and some other new makes in the territory are getting a gratifying start. The tire and accessory houses likewise report a substantial growth in business throughout the district.

The record sales increase found, where an established and extensive business is concerned, is the 500 per cent gain reported by W. W. Barnett, Oldsmobile distributor and president of the Automobiles Trades Association. This trades body, incidentally, by standardizing many features of the industry, introducing improved business methods, promoting harmony and co-operation among the dealers and otherwise building up the best and most practical interests of the motor industry, has accomplished a great deal in an organized way toward helping along this favorable showing in sales.

Koenig & Luhrs Wagon Co. Builds Truck Chassis

QUINCY, ILL., Feb. 19—The Koenig & Luhrs Wagon Co., this city, has begun the construction of motor truck chassis, the first one being completed on the fifteenth anniversary of the founding of the company. Before undertaking its new line the company installed the necessary machinery and employed a number of experienced mechanics to look after the new department. With the rapid substitution of motor vehicles for horses, the company may extend its activities to other fields of the industry.

Wisconsin Car Registrations Gain 100 per Cent on January, 1915

MADISON, WIS., Feb. 19—An increase of more than 100 per cent in the number of licenses issued to private owners of Wisconsin is noted for the month of January, 1916, compared with the corresponding period of 1915. Up to the end of January 28,500 licenses were issued, against 13,100 in January, a year ago. On February 15, the number of licenses issued 32,500, which figure maintains the 100 per cent increase. Applications are coming into the Secretary of State's office at Madison at the rate of 275 a day, and as the season advances it is expected that more than 500 requests will be filed daily. The 1915 registration of private owners was 79,791 and it is figured that the total for 1916 will be at least 110,000.

Omaha Expects Many Dealers

90 Per Cent of Those in the Territory to Attend Record Show

OMAHA, NEB., Feb. 21—Ten times greater than the first Omaha show of 1906, the eleventh annual exhibition, held in the municipal auditorium, displays over 200 cars, every available inch of space on the main floor and in the basement being taken. More than 90 per cent of the dealers in the Omaha territory are expected to attend the show and even a large portion of the remaining 10 per cent will probably drop in for at least a day during the week. Over sixty dealers are represented at the show.

There will be "days" for the ladies, the visitors from out of town, the farmers, and all the rest, of course, and extensive preparations have been made to make each of these an occasion in itself. For instance, on Farmers' Day there will be on hand a special corps of demonstrators from the factories who will supply any information which may be desired; there will be a special exhibition of tractors, as a direct recognition of the importance of the agricultural interests in the show, and special music designed will be furnished. And for every other day a similar provision has been made.

The decorations form a Japanese garden setting, the colors being orange, black and white lending themselves well to blend with the glow of the thousands of electric bulbs.

"Velie" is New Southern Town

VELIE, LA., Feb. 17—Many Velie cars are owned in the southern district, and as a result the name is well and favorably known. A community directly north of Shreveport, La., has assumed such importance that it was entitled to the post-office privileges.

Many meaningless titles were suggested and finally an enthusiastic Velie owner suggested the town be called "Velie." The name was indorsed by several other Velie owners present and adopted unanimously. Uncle Sam promptly approved the petition and Velie, La., is now an established fact.

Fisk Sales Total $14,500,000

CHICOPEE FALLS, MASS., Feb. 17—Sales for the fiscal year of $14,500,000 with net profits of $1,791,579 were reported at the annual meeting of the Fisk Rubber Co., held here yesterday.

On account of insufficient time action on the authorization of additional capital stock was not taken up and the meeting was adjourned until March 8 for action on this question. The present capitalization is made up of $5,000,000 first preferred, $2,000,000 second preferred, and $8,000,000 common.

The regular quarterly dividends of 1¾ per cent on the preferred stock, payable May 1 and on the second preferred stock, payable June 15 were declared.

The officers and directors were reelected, as follows: President, H. T. Dunn; vice-president, E. H. Broadwell; chief engineer, John Kearns; sales manager, J. D. Anderson.

Garford Truck Officers Re-elected—Report Prosperous Year

LIMA, OHIO, Feb. 19—The annual statement of the Garford Motor Truck Co., read at the annual meeting of the stockholders and directors, showed that the year just closed has been the most prosperous one in the history of the concern.

All the stockholders expressed themselves as well pleased with the report and voted to re-elect the same staff of officers and directors for the coming year. E. A. Williams will again serve as president and general manager; J. M. Carver will be secretary.

$800,000 Company to Take Over Delco House-Lighting Industry

DAYTON, OHIO, Feb. 19—The Domestic Engineering Co., incorporated with a capital of $800,000, has been formed to take over the Delco domestic light industry of the Dayton Engineering Laboratories Co., this city. The incorporators of the new concern, which will have practically the same organization as the Delco, are Edward A. Deeds, R. H. Grant and R. D. Funkhouser.

Mr. Deeds is one of the men who are backing the project to make a model community and industrial center south of Oakwood, approximately 3500 acres of land either having been purchased outright or secured by option for that purpose. Adam Schantz and C. F. Kettering are associated with him in this enterprise, and it has been announced that the new plant of the Delco, to be devoted to the manufacture of electric light outfits for farm and rural communities, will be built in that section.

Champion Spark Plug Gets Injunction

TOLEDO, OHIO, Feb. 20—The Champion Spark Plug has secured a permanent injunction against the Keystone Auto Supply Co., restraining the latter concern from manufacturing or selling an imitation of the Champion X spark plug for Ford cars. The decision was handed down by the District Court of western New York.

State of Iowa Now Has One Automobile to Each Fifteen Inhabitants

Farmers Estimated to Be Worth $1,000,000,000—This Means $100,000,000 Available for Automobile Buying—2587 Dealers in State

DES MOINES, Feb. 20—The Des Moines automobile show, which was held this week, is a show of promise. The dealers from all parts of the States which are served by Des Moines are looking for an increase, and not a decrease in 1916 business. The big distinguishing characteristic of the State is her always present market for her products, and this is because those products are foodstuffs.

Iowa now owns one car to every fifteen people, men, women and children. Line the population up in a row and every fifteenth person owns a car. In Buena Vista county there is a car to every person in nine, and by the end of 1916 the figure will be still more startling.

Products Worth a Billion

The per capita wealth of the United States is $1,965. In Iowa it is $3,345. The State has money; and it made a lot in 1915, and, furthermore, the Iowa farmer, with his modern lighting plant, plumbing and other improvements is not averse to buying a car if his year's business warrants it.

With products estimated at $1,000,000,000, the Iowa farmer should be a good car buyer. Of course, a large percentage of the billion will go for living expenses and operation of the farms, but if only 10 per cent of it is used for cars it means $100,000,000, and this means 100,000 cars averaging $1,000.

It probably will not be 100,000, because the normal progress of business is not subject to such sudden jumps. The following table shows the gains and percentage of gains during the past few years, and these must be taken into consideration in estimating for the coming year.

Year	Cars Owned	Cars Bought	Percentage of Gain
1911	27,998	,.....	..
1912	44,188	16,190	57
1913	70,068	25,880	58
1914	106,087	36,019	51
1915	145,076	38,989	36

The decrease in gain from 51 to 36 per cent for 1915 may be attributed to weather conditions. A normal gain, estimated on the three preceding years, is about 50 per cent. A 50 per cent gain would be approximately 75,000 cars for 1916. A gain of one-third would be 50,000 cars. With the possible buying power and the percentages of gain of preceding years as a basis, it is safe to estimate that Iowa will buy 75,000 cars in 1916.

There are in the State 2587 dealers. This means thirty cars to each dealer, and there are some who will sell many more than that. If each sale averages a profit of $200, which is low, it means a profit of $6,000 for each dealer. It means $15,000,000 in profits for the dealers of the State.

The Wealth of the State

Corn and hogs are a big product in Iowa. They have said that in Iowa corn is king; nobody has placed the hog on a throne, but if corn is king the hog is queen. The co-relation of these two products has helped Iowa through her present year. An early frost and rain hurt the corn; it produced what is called "soft corn," a corn which does not mature and harden in the ear. This might seem to be waste—but it isn't. It is excellent hog fodder if rightly fed. When the weather man said: "I'll spoil your corn," the Iowa farmer answered: "All right, I'll take my profit from pork." When Iowa is blocked at one point she pushes through at another. She won't be stopped.

Diversity of Products

That is why a 1915 crop of corn valued at only $154,530,000 is not a setback when compared with a 1914 crop valued at $214,183,000. It looks like a loss of 28 per cent—but it isn't. May and July corn are to-day selling within a few cents of the price of a year ago. Pork products are about $1 lower.

Iowa knows her salvation is in a diversity of products. For that reason the State is promoting agricultural study and research. Popcorn is becoming an important crop; 30,000,000 lb., valued at $625,000, were yielded in 1915. The farmers are scientific. The national government sent a man on a long pilgrimage to learn about popcorn, and it wasn't until he reached Iowa that he found what he wanted to know, which was what puts the pop in popcorn. The pop of perfection is caused by 12½ per cent of moisture in the kernel. And Iowa knows how to put it in, take it out and put it back in again.

Corn is a big crop, of course; so also are oats, wheat, potatoes, hay, barley, apples—which are a newcomer—and then there are the hogs, the beef cattle, the dairy products and other lesser food products. Iow'a specialty is feeding people.

It is true that the total value of the corn, oats, wheat, hay and barley crops are less by 13 per cent, and that the value of the live stock on hand Jan. 1 is 2 per cent less than a year ago, but it is also true that bank deposits increased about $20,000,000 during the year. Some of this money would have bought cars in 1915 had there been cars to buy, but car shortages were the big trouble of the dealers last year. There was plenty of money, plenty of orders—but no cars. Therefore, part of this banked $20,000,000 is still waiting to buy cars, and added to it is the natural production of the year.

As was stated previously, much of the poor corn was used to feed swine and cattle. Beef raising is becoming more and more a strictly Iowa industry. In the past it has been the custom of the Iowa farmer to go into the Omaha market and buy what are called "feeders," cattle which are bought for fattening during the winter and sold about now and during the spring. But the Iowa farmer has had to pay a higher price this

Iowa Farming Statistics

	Amount		Value	
	1914	1915	1914	1915
Corn (bu.)	363,689,600	303,000,000	$214,183,000	$154,530,000
Oats (bu.)	172,696,000	198,000,000	67,650,000	63,360,000
Wbeat (bu.)	15,427,280	15,557,000	14,463,000	13,535,000
Barley (bu.)	11,423,310	....	5,397,053	5,362,000
Potatoes (bu.)	9,540,200	15,540,000	5,533,316	8,392,000
Hay (tons)	5,094,650	6,692,000	52,769,626	66,920,000
Total			$359,995,995	$312,099,000

Decrease of $47.896,995, or 13 per cent.

	Number on Farms Jan. 1		Value Per Head		Total Value Jan. 1	
	1916	1915	1916	1915	1916	1915
Horses	1,580.000	1,600,000	$105.00	$105.00	$165,900,000	$168,000,000
Mules	61,000	58,000	110.00	111.00	6,710,000	6,438,000
Milk cows	1,390,000	1,377,000	58.50	57.00	79,249,500	78,489,000
Otber cattle	2,740,000	2,683,000	38.30	37.50	102,795,000	100,612,000
Swine	9,070,000	8,720,000	9.30	11.00	84,351,000	95,920,000
Sheep	1,270,000	1,219,000	6.30	5.50	8,001,000	6,994,000
Total value Jan. 1					$447,006,500	$456,453,000

Decrease of $9,446,500, or 2 per cent.

past year for feeders and anyway he is raising his own feeders. Swine, of course, are an Iowa product from pig infancy up.

Milk cows are not sold, but the State's dairy products are sold all over the world, and this industry is spreading. Horses have been and are being sold for war purposes, and the mule industry is gaining a footing. Some of the $20,000,000 that was banked in 1915 came from last spring's sales of stock, and during the next few months there will be a big income from feeders and swine.

One progressive step made last year in Iowa was vaccination against hog cholera. The results were invaluable. There was little of this trouble. What the coming months may mean in stock revenues is indicated by the value of the live stock on hand Jan. 1.

Bank Deposits High

Having cited production figures which show a lesser value for 1915 than for the preceding year, it is only fair to cite at the same time the bank deposits. They were, as given in a report of the banking department, $329,633,636.12 at the call of Sept. 11, 1915, and this exceeded the call of Nov. 4, 1914, but ten months previous, by $21,522,719.16, a gain of 6 per cent. Of this total deposits, 70 per cent is in savings banks.

Wants New Foodstuff

Iowa is all the time looking around for a new foodstuff to add to her resources. There is now on an agitation for apples. The Iowan believes the old State will grow almost anything—and he seems to be nearly right. And the more crops he can grow the smaller and smaller becomes the chance of breaking the record of "many misfortunes, but never a failure."

Farmers and Boosters

The Iowan is regarded as a farmer. It is true, he does this for a living, but his next biggest occupation is boosting. In not more than 60 seconds after an Easterner wandered into the automobile show the other evening he had been told that Iowa is first in value of farm products, value of live stock, value of farm property per farm, in increased valuation from 1900 to 1910, in percentage of improved farm land, in percentage of area in farms, in number of automobiles per capita, in value of horses, in value of cattle, in value of hogs, in number of poultry, in value of egg production, in tonnage of forage crops, in production of corn, in production of oats, in production of grass seed and a few other things too numerous to mention here—but the Iowan mentions them everywhere.

There is no question but what Iowa is a great State. If in doubt just mention the subject in the neighborhood of an Iowa man and hear him admit it.

How Pouring Gas Creates Electricity

—

Moline Co. Finds Fires Can Be Caused Even When No Chamois is Used

MOLINE, ILL., Feb. 21—In January, the Moline Automobile Co., East Moline, Ill., manufacturer of the Moline Knight engines and automobiles, had two fires caused by the ignition of gasoline when being drawn from one of their filling stations. The Moline Automobile Co.'s supply tank is located at some distance from filling stations. The gasoline is pumped through a 1½-in. iron pipe by means of an electrically-operated pump controlled at each of the filling stations. The two fires both occurred at the service department's station and within about a week of each other. This filling station is at the end of a long pipe line which leads through a duct beside an asbestos covered steam pipe. It had been noticed that the gasoline, especially that first to be drawn in the morning was very warm and, therefore, gasified readily. In both of these fires, it was noted that the gasoline ignited when the can had about four gallons of gasoline in it and before the control switch for pump was pulled.

Switch Spark Eliminated

As the control switch for the electric motor was situated near the drawing faucet, it was first assumed that possibly the explosion and fire occurred by the fumes catching from a spark due to bad switch connection. Therefore, immediate steps were taken to remove the gasoline pipe from the steam duct so that the gasoline would not be heated.

In about another week there was a similar fire, although not so much damage due to the presence of mind of the operator to shut off the gasoline. This time the explosion occurred after about 3½ gal. of gasoline was drawn. The man drawing the gasoline distinctly heard the snap and the explosion.

Investigation showed that the former theory of the fire was in error. It is believed that the fire was caused by static electricity jumping from the funnel of the can to the faucet. A 5-gal. can with a funnel but no chamois skin was used. The funnel rested in the neck of can and came in direct contact with the can. The can rested on a wooden box which formed a complete electrical insulator for the can. The height of the funnel was about the same as the faucet. Thus by movement of the can, the air gap between the funnel and the faucet could be changed. We found that static electricity is generated by the flowing of gasoline into the can. When there was sufficient static electricity generated in the surface of the can, making its potential great enough above that of the faucet, it would break down the air gap and jump from the funnel to the faucet. This would set fire to the gasoline.

Experiments showed that a spark could be drawn from can after it was partly filled with gasoline, providing it was left undisturbed on the wooden box. This spark could either be drawn by a wire direct connected to the piping system and therefore grounded, or even through a man's hand who was standing on the floor as he approached with his hand the surface of the can to about the distance of ¾ in. This spark is similar to one secured under certain atmospheric conditions by scuffing along a heavy carpet and touching some other person or conducting article.

Principle an Old One

This principle was discovered in the early days of the discovery of electricity and we find reference to an apparatus known as "Lord Kelvin's water dropping apparatus." We have learned since our fires that there have been similar cases of fires from apparently the same causes. In a recent publication of one of the trade papers there is published an article in which the author claims that the fire resulted from the gasoline being strained through a chamois, which generated the static electricity on the can or funnel. The experience of the fires at the Moline Automobile Co. shows that the chamois is not necessary, and that providing your can is well insulated and nothing touching it but electrical insulating material a charge of electricity will be stored on the surface of the can as gasoline is being poured into it.

Hang Can on Faucet

The reason for not having trouble at the other filling station is thought to be due to the fact that the cans are either hung on the faucet by the handle or rest on some metal grounded support.

The Moline company has installed at this filling station a metal rest instead of the wooden box. This metal is perfectly grounded to all piping.

The Moline Automobile Co. therefore wishes to warn all filling stations to be sure that the charge collecting on the can is properly disposed of and not allowed to build up. The can should be resting on some conducting metal properly grounded. If metal pipe is used, then pipe and can should be metallically connected in some way.

It is also to be noted that under this theory the can, while resting on some insulating material might be filled and carried by someone wearing gloves, which would keep the can still insulated and would allow the can to discharge static electricity to car tank or other metal and possibly when this spark is discharged, to set fire to the can of gasoline.

Security Prices Steady

Chevrolet and G. M. Stocks Higher—Chalmers Common Rises 20 Points

NEW YORK CITY, Feb. 21—Notwithstanding the statement of C. W. Nash, president of the General Motors Co., that the stockholders of the company could not expect it to make as great earnings for the remainder of the fiscal year as were made from July, 1915, to Jan. 31, 1916, a number of the automobile and accessory issues showed substantial gains for the week. Some of the automobile securities, however, have been extremely weak. The statement caused a little selling of Maxwell Motors and Studebaker, but nothing of any importance. These two issues, together with Willys-Overland, were quoting considerably lower than in the previous week. However, the market, notwithstanding these declines, was on the whole, about 20 points higher than last week.

Chalmers featured the securities with a 20-point rise, closing on Saturday at 130. General Motors, on the strength of its recent financial statement, managed to hold above 475, closing on Saturday 2 points above that mark. Chevrolet also held strong at 134 with a gain of 4 points. It is stated that this company should show $6,000,000 earnings this year.

A few of the tire issues last week showed strength. Firestone common went up 5 points, closing at 735, and Goodrich common went up ⅛ point. This company announced its 1915 earnings last week, showing a surplus of 17 per cent on its common stock, and paid out $600,000 as a dividend on its common stock. This is 1 per cent on the issue of $60,000,000 of the common stock. Two quarterly dividends on the $28,000,000 preferred stock have been declared at the rate of 1¾ per cent quarterly, payable April 1. Miller Rubber common also showed a gain, closing at 275, just 2 points higher.

The drops this week were for the most part in the automobile stocks. Studebaker common, which has been one of the chief speculative stocks, closed on Saturday at 146 at a loss of 7 points; Maxwell common, first and second preferred, dropped 4¼, 1 and 1¼ points, respectively, and Willys-Overland common, which has shown considerable strength during the past few weeks, declined 13 points, closing on Saturday at 208.

The Detroit issues were featured last week with 100-point rise, after a 60-point rise the previous week. Chalmers common rose 16 points and Packard common 5 points.

The stock of the Auto Body Co., Lansing, Mich., will be listed upon the Detroit Stock Exchange. The capital stock of the company is $500,000. During 1915 the company paid its stockholders a 15 per cent cash dividend and 75 per cent in stock dividends.

Edmonds & Fulton Is New Firm

DETROIT, MICH., Feb. 21—Edmonds & Fulton, is a new firm formed in Detroit to act as manufacturers' representatives. J. D. Edmonds and H. S. Fulton are the partners who have taken quarters in the Majestic Building. The Perry-Fay Mfg. Co., Elyria, O., and the Pittsburgh Screw & Bolt Co., are among the concerns represented by the new firm.

American Motor Corp. Organized

$1,250,000 Co. To Build Cars—Louis Chevrolet Chief Engineer

NEW YORK CITY, Feb. 21—Louis Che rolet and a group of Eastern busine men, including W. H. Hoople, preside of the Interstate Electric Corp.; J. Spiers, formerly general manager of t Autocar Co. and factory manager of t Locomobile, Mercer, S. G. V. and Stan ard Roller Bearing companies, and G. Baright, formerly advertising manag of the Prudential Life Insurance C Newark, N. J., have completed the orga ization of the American Motors Cor which is to engage in the manufactu of automobiles on a large scale.

The company is capitalized at $1,250,0 Its first output will consist of a mod ate-priced car. Louis Chevrolet, vi president and chief engineer of the co pany, is also president of the Fronten Motor Co., Detroit, builder of racing c of his design.

The main plant of the new compa will be located in the East in order gain ready access to this market.

Copper and Aluminum Prices

NEW YORK CITY, Feb. 21—Materi prices last week were generally stea most of the prices remaining unchang Both copper and aluminum prices vanced while Up-River Para rubber clined 3 cents a pound to 76. Elec lytic and lake copper are quoting at

advance of 1 cent a pound over last week's quotations, which were 27½ cents for each of the two grades. Aluminum has gone up to 57 cents a pound at an advance of 1 cent. The metals have been the feature of the materials market. The demand has been very large, notwithstanding the high prices.

Rubber prices, which created much comment recently, have again reached something like normal. Fine Up-River Para, which fluctuated throughout the week, closed on Saturday at 76. The Ceylon, First Latex Crepe grade, saw a gradual rise of about a cent a pound per day, closing on Saturday at 91, just 2 points higher. The demand for rubber is active, but manufacturers do not show much disposition to anticipate requirements in making purchases of crude material.

Prices in the oils and lubricants were constant. Linseed oil advanced 1 cent. The rest of the prices were unchanged. Gasoline is still quoting at 23 cents with rumors of a further advance in the near future.

Rayfield Motor Car Co. Defunct

CHRISMAN, ILL., Feb. 19—The Rayfield Motor Car Co., this city, is now defunct. The entire belongings were sold at auction under decree of the Federal Court. The machinery and office fixtures were distributed among St. Louis, Indianapolis and Chrisman buyers, the amount realized aggregating $14,000. F. K. Thayer, of Chrisman, purchased the building for $2,500. No bids were received when the plant was put up as a whole and it was necessary to sell each portion separately.

Cornell, Speaker at Indiana Section of S. A. E.

INDIANAPOLIS, IND., Feb. 19—The February meeting of the Indiana Section of the Society of Automobile Engineers will be held at the Claypool Hotel, Friday, Feb. 25 at 8 p. m. The topic is "Anticipating Complaints" and the author of the paper is F. A. Cornell, formerly head of the service department of the Willys-Overland Co.

Atlas Ball Co. to Expand

New Plant Will Quadruple Production—To Be Finished in 3 Months

PHILADELPHIA, PA., Feb. 16—In about three months the Atlas Ball Co. will move into its new plant which will have a capacity four times as great as the present factory. The growth of this concern is indicative of the tendency toward buying parts in this country which manufacturers formerly believed could not be made as well here as abroad. The European war has afforded an opportunity for many of the domestic manufacturers to show that their products can readily take the place of the European and the Atlas Ball Co. is a concrete example of this, as the business for 1915 is 95 per cent greater than it was in 1914 and the plant is at present working 22 out of 24 hr. The rate of manufacture has grown to such an extent that the company is now turning out in one month as many balls as were made in the entire year 1911. The balls made by this concern range in size from 1/16-in. up to 2½-in. and are used by very many of the ball bearing manufacturers in the country.

Fletcher Resigns from Stewart Motor

BUFFALO, N. Y., Feb. 17—H. R. Fletcher, for several years past connected with the Stewart Motor Corp., Buffalo, N. Y., as sales manager, has resigned to become a director and manager of the Triangle Motor Sales Co., 1872 Broadway, New York City, this company having been organized as the New York City selling agency for Stewart delivery trucks.

Many Dealers Driving Home New Cars

DETROIT, MICH., Feb. 18—Although this is not yet exactly drive-away weather, a number of such events have taken place from local and other Michigan automobile factories. They were, however, planned simply as a means of securing cars quickly or rather quicker than it would be possible to get them when shipped by rail. It is all due to the freight car shortage situation.

While in Toledo a few days ago, your correspondent was informed by the Saxon distributor that thirty of his agents responded to his suggestion to come to the factory in Detroit and drive away their new cars, as otherwise it might be a case of at least ten days before the cars would reach them.

From Lansing came the news that Reo dealers have already started the annual drive-away period, only because they are clamoring for cars and can't get the promise of an early delivery by rail.

The Hupp Motor Car Co., the Studebaker Corp., the Maxwell Motor Co., and others already had a few drive-aways and will have more from now on.

The Charles E. Reiss Co., New York distributor for the Hupmobile will have its cars shipped only as far as Poughkeepsie, N. Y., from where the cars will be driven overland. Some shipments may also be coming by lake steamer to Buffalo, from where there will then be a drive-home.

New Bus Bodies Much Improved

NEW YORK CITY, Feb. 22—The new metal bodies designed and built by the Fifth Avenue Coach Co. for application to its bus chassis are being installed in place of the old ones at the rate of one every two days. The new bodies are 800 lb. lighter than the twenty-four-passenger bodies formerly used, yet they seat ten more persons. They are even lighter in comparison with the forty-five passenger bodies used on other of the chassis.

The new bodies are being equipped with Perfection exhaust heaters, made by the Perfection Spring Co., Cleveland, Ohio. These heaters will use all of the exhaust and while in use will eliminate the silencer. A new type of sign is being developed which is more legible than the former type, it is more accessible for adjustment and it is expected that both front and rear signs will be used when the latter are perfected.

Sheridan Truck Motor 2¾ by 4 In.

NEW YORK CITY, Feb. 19—In THE AUTOMOBILE for Jan. 22 a typographical error made it appear that the four-cylinder motor of the Sheridan light truck built by the Sheridan Commercial Car Co., Chicago, Ill., was 2 by 4 in. This should have been 2¾ by 4 in.

Now Continental Motor Co.

DETROIT, Feb. 17—At the stockholders' meeting of the Continental Motor & Mfg. Co., it was decided to shorten the name of the company which will hereafter be Continental Motor Co.

Factory Miscellany

Michigan Truck Adds—An addition, 32 by 100 ft., is being put up at the plant of the Michigan Truck & Lumber Co., Holly, Mich.

Dunlop Tire Adds—The Dunlop Tire & Rubber Co., Toronto, Ont., will immediately commence the erection of an addition to its plant.

Motor Truck Body Co. to Build—The Motor Truck Body Co., Detroit, Mich., is constructing a one-story, 64 by 245-ft. factory in that city.

Ajax to Build—The Ajax Rubber Co., Trenton, N. J., has taken out a permit for the erection of a three-story brick and steel plant to cost $75,000.

Fleetwood to Add—The Fleetwood Metal Body Co., Fleetwood, Pa., has increased its capital from $25,000 to $115,000, and plans to increase its business in proportion.

Murray Parts Co. to Add—The J. N. Murray Mfg. Co., Detroit, Mich., manufacturer of automobile parts, will construct an addition to its plant costing approximately $10,000.

To Make Tractors—The Bettendorf Trailer Co., capitalized at $100,000, has been formed to build tractors in Bettendorf, a manufacturing center near Davenport ,Iowa. J. W. Bettendorf is president of the company.

Packett Co. Formed—The Packett Motor Car Mfg. Co., St. Paul, Minn., has been formed with a capital of $150,000 to manufacture a light delivery truck and will build a factory. Henry Orme is president of the company.

Fisher Body in Krit Plant—The plant formerly occupied by the Krit Motor Car Co., Detroit, Mich., has been leased by the Fisher Body Co. and is now one of this concern's local manufacturing branches. About 150 men are on the payroll now.

Howe Rubber Adds—The Howe Rubber Co., New Brunswick, N. J., advises that on account of the protracted delay of 3 or 4 months before it could rebuild its tube plant, which was destroyed by fire at a reported loss of $150,000, it has decided to put up a concrete addition to its new tire department and move its tube business into that building. It plans to start operations in the new building about March 1.

Ford Community at Milwaukee—A Ford community is being built around the new Ford branch plant at Prospect Avenue and Kenilworth Place, Milwaukee, Wis. The latest addition is a banking institution, known as the East Side Bank, which is incorporated with $25,000 capital, and will open about March 1 at Farwell and North Avenues, a block from the Ford works. The bank will cater to employees.

To Make Electrical Apparatus—The Lake Superior Electrical Co., Superior, Wis., organized by M. B. Benson, E.E., to manufacture electrical apparatus, signal devices and similar appliances, has started operations in leased quarters in the plant of the Superior Iron Works. The initial force consists of forty-five skilled electricians. The new company has established a storage battery department and has installed a complete battery charging outfit for the convenience of Superior motorists and electric owners.

The Week in the Industry

Hillman Resigns from Willard—M. G. Hillman, district sales manager in Detroit for the Willard Storage Battery Co., Cleveland, Ohio, has resigned.

Fisher is Steinhart Manager—Walter M. Fisher, formerly manager of the Cadillac Co. of Illinois, has been appointed manager of the E. W. Steinhart Co., Indianapolis, State distributors for the Dodge.

Townsend Resigns from Bowser—G. A. Townsend, Jr., of S. F. Bowser & Co., Fort Wayne, Ind., has resigned as advertising manager of that concern, effective March 3. He has been with the Bowser company for six years. As yet no successor has been named.

Dealers

Philadelphia Trade News—The Braender Rubber & Tire Co. has opened a branch at 1327 Race Street, Philadelphia, in charge of W. L. Porter.

The Berrodin Rubber Co., Philadelphia, will add to its present line of tires an automobile-accessories department.

Chicago News Items — The Braender Rubber & Tire Co. has opened a branch at 1350-54 South Michigan Avenue, Chicago. This branch is in charge of W. J. Heathcock.

The McCullough Motor Supply Co., Indianapolis, Ind., has opened a branch office in Chicago and Cleveland. This company handles automobile parts and accessories.

The Joseph T. Ryerson & Son Co., Chicago, will carry Fahrig metal and fill orders to the retail trade in the territory west of and including Pittsburgh.

New York City Items—J. A. & W. Bird & Co., maker of the Ripolin enamel paint, Boston, has changed the location of its New York City offices from 66 Beaver Street to the Equitable Building, 120 Broadway.

The Elkhart Carriage & Motor Car Works, makers of the Elcar, have placed their wholesale and export business in the hands of the Kent Motors Corp., 1704 Broadway, New York City, distributor of the Marion car.

Texico Garage Capital $1,000,000—The Western Tire & Garage Co., which was recently organized in Texico, N. M., has a capital stock of $1,000,000. It has begun business, however, with a cash capital of $2,000. The big capitalization of the company gives it plenty of room for expansion. It is perhaps the largest capitalized garage concern in the United States.

Motor Men in New Roles

Bender Joins St. Louis Packard—Paul Bender, formerly European manager of the Burroughs Adding Machine Co., with headquarters at Berlin, on March 1 will join the force of the Packard Missouri Motor Co., St. Louis.

Gill Saxon Factory Manager — R. O. Gill, who has been assistant factory manager of the Saxon Motor Car Co., Detroit, has been promoted to factory manager. Before coming to the Saxon organization Gill was with the Chalmers Motor Co.

Dold Heads St. Louis Goodrich—W. C. Dold, formerly of the Kansas City Goodrich branch, has been appointed manager of the St. Louis Goodrich branch to succeed L. K. Rittenhouse, resigned. O. E. Hoerger, who has been acting manager at St. Louis, will remain as assistant to Mr. Dold.

Dyke Issues Free Supplement — A. L. Dyke of St. Louis has just issued a free supplement in two colors treating on the construction, principle, operation, care and adjustment of the Packard Twin-Six, King Eight, Willys-Knight, Ford and Maxwell. This is included free without extra cost with Dyke's 1915-16 Encyclopedia.

Holden Joins Service Truck — A. E. Holden has joined the Service Motor Truck Co., Wabash, Ind., as assistant sales manager. For over five years he was advertising and sales manager of the Double Fabric Tire Co. Previously he was connected with the sales department of the McIntyre Automobile Co., Auburn, Ind.

Nicholai Joins Leavitt—L. G. Nicholai, well known in automobile and newspaper circles on the Coast for a number of years past, is now identified with J. W. Leavitt & Co., Pacific Coast distributers for Overland and Willys-Knight. Mr. Nicholai will have charge of the advertising of this concern and Overland publicity and promotion work in the Northwest territory. His headquarters will be at San Francisco.

Bauer in Tire Business—H. A. Bauer, identified with the automobile industry for twelve years and for a long time connected with the Oakland Motor Car Co. in various capacities and finally the assistant sales manager of that company, has gone into business for himself in Detroit, having organized the Wolverine Rubber Co. He will be located at 2301 Woodward Avenue, and he will specialize in the wholesaling of automobile tires.

McCallum Joins Doehler—H. C. McCallum has joined the Doehler Die Casting Co., Toledo. He is in the sales department.

Wood Firestone Seattle Mgr.—E. R. Wood of Los Angeles has been named manager of the Seattle branch Firestone Tire & Rubber Co. C. W. Brown, retiring manager, has been made special representative on the Pacific Coast.

Pyke with N. Y. Mitchell—Harry Pyke has been made manager of the Carl H. Page Co., New York City distributor for the Mitchell. C. M. Welch has joined the sales force of that company and will assist Mr. Pyke.

Dealers

Overland Building in 'Frisco—The Willys-Overland Co. has purchased a lot on Van Ness Avenue, San Francisco, Cal., and will immediately start the erection of a $400,000 building, which is to be used as the headquarters of J. W. Leavitt & Co., Coast distributer of the Overland car, and the Coast factory headquarters. The building will be a six-story structure with approximately 185,000 sq. ft. of floor space.

Denver Trade News—The Schwalbert-Dorris Co., a new concern, has opened a Dorris distributing agency for Colorado at 1240 Broadway, Denver.

A. C. Wagner, manager of the Wagner Garage Co., 1541 Cleveland Place, Denver, and W. H. H. Cranmer have secured the Colorado distributing agency for the Kelly-Springfield truck.

The International Rubber Co. is the new name for the Colorado Tire & Leather Co., 985 South Broadway, Denver, which manufactures rubber and leather half-soles and treads for tires.

F. J. Silbanck has opened an agency at 1541 Cleveland Place, Denver, for the Even Lite for Ford cars.

The Gessler-Williams Tyre Co., agent for Swinehart tires, has moved from 1560 Broadway, Denver, to 1312 Broadway.

The Wagner Garage, 1541 Cleveland Place, Denver, has been appointed as a Buick service station.

The C. & S. Sales Co., 1742 California Street, Denver, is a new concern manufacturing Randolph springs for distribution in the Rocky Mountain territory. F. E. Coe is president and C. R. Stedman is secretary-treasurer.

Payne Bros. have opened an International tire half-soles agency at 1560 Broadway, Denver, under the name of the International Sales Co.

Marathon Tire Enlarges at Omaha—The Marathon Tire & Rubber Co. has taken over the business of the Akron-Marathon Rubber Co., consolidating the latter with the factory office and warehouse in Omaha, Neb., enlarging their staff and facilities. The management and selling force are the same with additions. H. H. Replogle is division manager for the Middle West, with headquarters at Omaha.

Overland Builds in Kansas City—The Willys-Overland Co. has completed the purchase of the acre tract of land at Twenty-first Street and Grand Avenue, Kansas City, Mo., and will start construction work at once on a seven-story sales and storage building. The four-story building at 2110 Grand Avenue, now housing the local branch of the Overland company, will be sold, despite the fact that plans had been drawn and contracts let for its enlargement.

The proposed building will have a frontage on Grand Avenue, McGee and Twenty-first Streets, and will cost about $600,000. Work on it will probably start March 5 and be rushed so that it may be occupied in August. It will be constructed to afford a large salesroom for new cars, a salesroom for second-hand cars, a repair department with space sufficient to permit work on a hundred cars, a department in which $250,000 worth of Overland parts will be kept on hand, a paint shop, a body shop, a machine shop, a storage capacity for 500 machines and the offices of the factory branch.

The building will not be a warehouse or an assembling plant. In announcing the contemplated improvement, it was given out that the company intends to acquire a warehouse site on the outskirts of the city and that an ultimate investment will be made here of $1,500,000.

Minnesota News Items—The Maxwell Motor Sales Corp., distributer for the Maxwell car, has bought a block of land 330 ft. long at Twenty-sixth Avenue, Southeast, and Delaware Street, Minneapolis, upon which it will erect an assembling plant. The company is now at Seventh Avenue, South, and Third Street in a large building, but the new structure will be adapted to more efficient use. F. W. Warrington is district manager.

B. W. Harris, representing Harris Bros., Chicago, announces a $350,000 plant will be erected in the Midway district to make gasoline engines. The C. A. Stickney Co. plant at St. Paul was recently bought by Mr. Harris and he said either a milling concern or an automobile factory may be established there. The new plant will make gas engines of the Stickney type, will operate a repair department and manufacture several lines of machinery.

Kansas City Changes—The Western Auto Supply Co., 1426 Grand Avenue, Kansas City, has been reorganized, and Don A. Davis has been elected president and treasurer. Mr. Davis purchased half interest in the company from George Pepperdine, who still retains an ownership, but is retiring from active work on account of his health. H. R. Baker is vice-president and E. R. Baker secretary.

The Studebaker branch has moved into its new six-story distributing warehouse on the northeast corner of Twenty-first Street and Grand Avenue. The new quarters are 120 by 150 ft., with storage room for 300 cars and additional space for a showroom, shop and used car storage. In the year 1915 the Kansas City branch handled cars valued at about $4,000,000. A. W. Daley, the retail salesmanager, predicts an increase of 50 per cent for 1916.

St. Louis News Items—W. L. Hausman, secretary of the Velie Automobile Co., St. Louis, has resigned to become associated with Price, Waterhouse & Co., public accountants. Mr. Hausman also has disposed of his stock in the Velie company.

The Entz Automobile and Battery Co., St. Louis, announces that it is now the official Detroit Electric garage and Southwestern representative of the Philadelphia Storage Battery Co.

The Cartwright Motor Car Co., has moved its salesroom from 3003 Locust Street to the new building occupied by the Commercial Auto Body Co. at Sixteenth and Pine Streets. Hugh F. Cartwright is president of both companies.

The Moon Motor Car Co., St. Louis, has moved its showroom from 3003 Locust Street to larger quarters at 3040 Locust Street. Similarly the Newell Motor Car Co. of St. Louis has increased its display space considerably by moving from 308 North Twelfth Street to 3003 Locust Street.

The Imperial Motor Car Co., St. Louis, has moved from 1045 North Grand Avenue to 2000 De Kalb Street in order to obtain larger quarters.

Plans for the immediate erection in St. Louis of a $250,000 Overland branch building were announced recently by the Overland Automobile Co. of that city, which acquired a quarter of a city square on the southwest corner of Twenty-third and Locust Streets.

The Park Automobile Co., St. Louis, has opened a new sales room at 2226 Locust Street for the display of the Chalmers line.

The Steele-Morgan Motor Car Co., Euclid and Taylor Avenues, has been given the agency for the Autocar in the St. Louis district.

The St. Louis Sectional Garage Co. has been formed by Eugene H. Angert, Frank H. Sullivan and Edward W. Lake with a capital stock of $5,000 to manufacture a portable garage.

Trade News from the Northwest—Gerlinger Motor Car Co., Portland, Ore., has taken the Oregon agency for Swinehart tires. J. F. Chapman is in charge of the tire department.

The Northwest Buick Co., Spokane, has opened new quarters at 1308 First Avenue.

The Interstate Auto Co., Spokane, distributor Interstate and Velie lines, has moved into new quarters at 1223 Sprague Avenue.

Glendale Auto Brokerage Co., Tacoma, has opened at 2913 Sixth Avenue. W. G. Rowland and G. N. Bissell are proprietors.

The Sieler-Inman Auto Co., Spokane, have been organized to handle he Case automobile in the Inland Empire. The territory includes eastern Washington, northern Idaho and western Montana. Henry and Victor Seiler and Elmer Inman are members of the new firm. The salesroom and service station are located at W-1017-19 Sprague Avenue.

Auto Tire & Rubber Co., Seattle, has opened new quarters at Seventh Avenue and Pine Street. D. E. Marriott is president and treasurer. With him is now associated H. J. Holmes as treasurer of the company.

J. P. Corey of the Seattle sales staff of the Rothweiler Truck Co. has left for San Francisco, where he will look after the interests of his firm and establish a branch, and S. F. Donnell of the same company will establish a branch in Minneapolis and direct the sales campaign for Rothweiler trucks in the Middle West.

New Chalmers in Kansas City—The factory branch of the Chalmers Motor Co. here has been discontinued and the distributing agency in the Kansas City territory has been taken over by the newly-organized Chalmers Motor Co. of Kansas City. The new company is headed by Lewis T. Shelton, part owner and manager of the Packard company here. He will also continue to manage the Packard agency. E. L. Knott will be the manager of the new Chalmers company.

The Chalmers company will open a new salesroom at 1506-8 McGee Street, but will continue its service and stock depot at 1728 Walnut Street.

Gets Rainier Park Concessions—Concession for all privileges within the Rainier National Park, including transportation to the park from Tacoma, Seattle and Ashford for a period of twenty years has been granted to the Rainier National Park Co. composed of Tacoma and Seattle business men, by the Interior Department. Headquarters of the new company will be in Tacoma. The company is capitalized for $200,000. All concessions within the park with the exception of the National Park Inn have been turned over to the Rainier company.

The AUTOMOBILE

New England

World's Greatest Department Store

¶ Her Machines Are Used in All the Factories of the World—Her Aid Is Given in Clothing All Nations—Her Leather Industry Is International—Agriculture and Lumbering Are Factors.

¶ Her Buying Capacity, Always Large, Is To-day at Full Tide—Her Factories Are Working Ceaselessly—Never Was Her Prosperity Greater Nor Her Prospects Brighter.

¶ Her Automobiles Have Gained 27 Per Cent in the Past Year—Her Purchasing Capacity Exceeds a Third of America's Automobile Output—She Has $500,000,000 of Unexpected Wealth.

NEW ENGLAND is the greatest department store of the world. Alone and unaided she can supply almost everything that civilized man desires or needs, and all she asks is the rawest of raw material in return. Feed New England with steel, with cotton and with hides and she will feed, clothe and equip you for any enterprise.

To-day New England boasts a territory roughly 3 per cent of the whole of the United States, but that area contains 7 per cent of the population. The six New England States together cover less ground than is included in each of eight single States in the Union. Texas, two and one-half times as large as all New England, has but a little more than half the population; Oregon, the same size as the six States, has but a tenth the number of people.

The Universal Provider

When first opened up the vast richness of the central and Pacific States dazzled for a time, but the development of the newer lands began around New England, and the pioneer districts looked always to New England to supply the goods of civilization that are the essentials of the creators of new communities. New England has been called the tool room of the world, and not inaptly; but let it not be forgotten that it was also the nucleus, the storehouse and the base for all Northern America; that there is no State in the Union and no country on the globe that does not still depend upon New England for many of the necessaries of life.

Ever Growing Prosperity

Like all other places, New England had its lean years and its fat ones, but through all of these a steady growth in population and a steady increase in individual wealth has been apparent. Does a new manufacturing industry arise, it is New England that exploits it and, though none too favored by climate, New England remains a great farming country.

Were some vast cataclysm of nature to remove these six fertile States, fertile of men and machines as well as crops, and two-thirds of the world would perforce go unshod, while countless thousands would be forced to garb themselves in something nearer the primeval style than cotton fabrics or woolen cloths. Halt the machine tool factories for a year and there is no manufactured thing throughout the world that would not rise in price. Flood the forests of Maine and Vermont and we should see some interference with the wood pulp and the paper trade.

Five Primary Industries

There are in New England five great industries, the primary five they might be called. Firstly comes the bodily equipment of man, textile products, both woolen and cotton. Secondly is the leather trade, which makes a large proportion of the boots and shoes of the world. Thirdly, in normal times, are the tools with which civilized man earns his living, either the actual implements as are used by the mechanic or machines which are an intermediate stage in the fashioning of other tools. Fourthly comes produce of the soil. A little grain, a little fruit, many potatoes, together with much of man's simplest luxury, tobacco. Fifthly is lumber, mostly in the form of wood pulp for paper making.

The five primary products of New England thus might be classified as modern man's four chief necessities, clothes, tools, food and the raw material of intercommunication between man and man.

Numerous Small Industries

New England has a host of smaller products which are important in the aggregate. Marble and building stone come from the quarries of Vermont. From the Atlantic coast the inland gets the fish trawled for on the Grand Banks. Technical and educational books are another important product, even education itself, if you can call education a product of industry. Jewelry, watches, toys and an everlasting list of lesser things make up the vast total of civilization's complex necessities.

This is why New England is the main department store of the world.

Prosperity Grows Steadily

It is agreed that never has New England seen such prosperity as in the past twelve months. Naturally, a place that supplies so large a proportion of the world's necessaries must perforce be prosperous when the world's demand is large, but to turn that obvious prosperity into dollars and cents is not easy.

In 1910 the national census gave some idea as to the relative positions occupied by the different sources of New England wealth. It showed that the textile industry was about twice as productive as the leather trade, that machines and metallic products about tied with boots and shoes; that farming was the third most important activity of the six States. Putting figures of merit against the different sources of new England wealth the census showed somewhat as follows:

Textiles	6.25
Boots and shoes	2.93
Metal products—machines and tools	2.85
Farming	1.41
Lumber (mostly wood pulp)	0.83

Now the figures from which these deductions were made are not collected every year. Actually it is for farming alone that definite government returns are made. It might be thought that in six years there would not have been much development in the oldest art of civilization, yet comparisons show that the value of farm products in New England for 1915 is more than one and a half times as much as it was in 1910. To be exact, in the proportion of 2.17 to 1.41.

This is because both output and price show a rise, the New England farmers are getting more from the land and are obtaining a higher price in the market.

Factories Never Stop

In textile work and in the leather trades we see in 1915 a condition never before equalled. Instead of working on a normal ten-hour-a-day schedule, a majority of the plants have been in practically continuous operation. Doubled and more than doubled outputs are to be found everywhere. There has been no stocktaking; there has been no time for it, but to estimate that the earning power of the industries is double what it was in 1910 is conservative.

Vast Rise in Metal Products

What then of the metal trades? The imagination is almost staggered by the vastness of the increase. Not a plant but is running day and night and Sundays; not a plant but has increased its hourly output; not a plant but is employing more men over and above those needed for the extra shifts. In Rhode Island alone it is agreed by the authorities that $120,000,000 is altogether too small a sum properly to represent the *increase* in the earnings of capital and labor. Massachusetts reckons about an equal sum and Connecticut a larger amount. Say these three States have, by their manufactures alone, earned $400,000,000 more in 1915 than is their normal, and one is still well on the safe side.

The accurate statistics of agriculture in the six States of New England show increased earnings totalling $53,000,000. Lumber has gained a little, while the factories of Maine, Vermont and New Hampshire, smaller in importance though they be, have none the less been swamped with business.

More Than $500,000,000

Five hundred million dollars is altogether too small a sum properly to represent the *extra* money New England has earned from the rest of the world in 1915.

Of course the population of the six States has increased also. Taking the normal rate of increase and adding a little to allow for the influx of workers in the past twelve months, we arrive at a figure of about 7,000,000 men, women and children. The normal per capita wealth of the inhabitants of the United States was just over $1,300 in 1914. Ten years before it was about $1,200, so the normal rate of increase is not more than $10 per annum. Spreading the extra $500,000,000 New England earned last year over her 7,000,000 population and we get a per capita increase of over $70; seven times the normal increase for a year. Furthermore, it may be remembered that this increase is not properly spread over a whole year. Many of the New England factories were rushed with work a year ago, but not all of them by any means, and there was a noticeable increase in the pressure during the summer, so it is fair to estimate that New England has, during 1915, raised her per capita wealth 750 per cent of the normal yearly rise.

High Per Capita Wealth

Take it another way and, regarding the per capita increase as a percentage of the normal per-capita wealth, we see that there has been a very large rise. Of course the New Englander is better off always than the average for the whole country, so let us assume that the per capita wealth of New England was $1,500 in 1914. Add $75 to $1,500 and we get a 5 per cent increase in capital value of each inhabitant, a pretty substantial rise for twelve months.

Prosperity Not Due to War

Ask almost any man, and he will answer that the prosperity of New England is undoubtedly enormous, and, he will add, due to war orders. This popular view is not wholly correct, for although New England is making munitions and supplies of one sort and another for troops; these war orders have not made the immense difference in the state of New England's business which actually exists.

Europe Ceases Exportation

The true way to regard the prosperity of New England's factories is to recall the fact that *Europe has ceased to export.* Thus we find many markets formerly supplied from England, from France or from Germany turning to America for their supplies. It is a very striking fact indeed that so many of the New England factories report the possession of good contracts with various of the South American republics. In a great number of instances the manufacturers report that they have secured very desirable customers in this way, that the present orders from this source are keeping them very busy and that the quality of the goods is being appreciated so greatly that the foreigners will have a very hard struggle to get back in the market again in the future.

America Takes Bulk of Output

Then, too, the demand upon America to generally look after and care for the world while the rest of it fights has brought prosperity to the whole of the United States, so that the domestic trade of New England is booming. In the automobile industry the demand for tools and plant equipment has been unprecedented; building, which has shown immense activity the past few months, demands all sorts of the smaller New England metallic products, and so the argument can be extended. Take away from New England all her munition orders, all her orders for clothes and boots for the armies, and she would still be very busy indeed.

What does this prosperity mean to the automobile trade? It means that the buying capacity of New England is far greater than ever before. Here is 96,000 square miles of territory with 7,000,000 inhabitants and $500,000,000 *extra* to spend or to invest: $500,000,000 unexpected money which will be expended somewhere.

Could Buy a Third of Automobile Output

It is estimated that the value of the automobiles to be made in America this year will be $1,300,000,000, so New England could, if she wished, buy about 38 per cent of the whole with the money already earned to say nothing of the money now being earned at an even faster rate than prevailed throughout 1915. To estimate how much New England actually will spend upon cars is impossible, but if she puts aside 20 per cent, $100,000,000, for this purpose it will take the automobile manufacturers all their time to fill even a part of the demand.

A long ago idea of what the automobile should be.—An advertisement in "The Motor Vehicle Review" of 1899.

New England Registrations Total 185,363 Cars and Trucks

39,331 More in Use in That Territory Than at the Close of 1914—38 People Per Car—20,804 Commercial Vehicles—2812 Dealers, Garages, Etc.

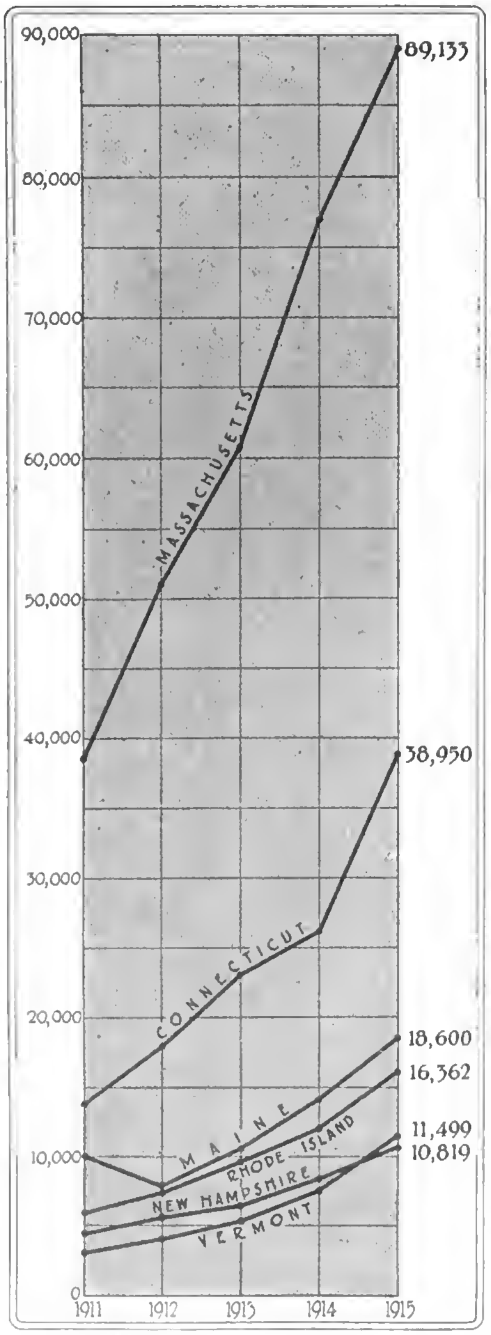
By Donald McLeod Lay

REGISTRATION statistics for the calendar year 1915 indicate that the six New England States, Maine, New Hampshire, Vermont, Massachusetts, Rhode Island and Connecticut, are all still far from the saturation point as regards their capacity to purchase automobiles and motor trucks. The average population-to-car ratio for this group of States is 38 to 1, or slightly higher than the average ratio for the entire country, which is 42 to 1. Of all the States, Iowa holds premier position in population-to-car ratio with a 16 to 1 proportion. The highest New England ratio is 32 to 1, Connecticut and Vermont both attaining this relation and Rhode Island having 37 to 1. Maine, Massachusetts and New Hampshire each have 41 to 1.

A Big Field

It is readily seen that Iowa's ratio is the logical mark at which New England should aim, although her rich agricultural acres enhance the car-buying capacity of this State to a degree that New England, with its large areas of untillable mountain country and unproductive lakes, perhaps can never attain. A comparison of what Iowa and the New England group have accomplished, however, brings out very strongly the latent possibilities in New England as a field for the automobile and motor truck manufacturer and dealer.

If New England, with a population of 7,108,003 on Jan. 1, 1916, had one motor vehicle for every sixteen persons, as is the case in Iowa, she would have a total of 444,250 cars and trucks. In other words, with her total registration of 185,363 at the end of 1915, she has yet to buy 258,887 machines to be on a par with Iowa in respect to population-to-car ratio. Of the total of 185,363 registrations at the end of 1915, there were 20,804 motor trucks of various sizes and types.



Registration in New England since 1911

But, although yet far from the population-to-car ratio of a number of other States, the New England group made very substantial gains in registration during 1915, the number of cars and trucks added to their records during the year being 39,331, or a gain of 26.9 per cent. As compared with the first reliable statistics available, the registration reports for 1911, the latest figures show a gain of 108,875 cars and trucks during the five years, or 142 per cent, since the 1911 total was only 76,488.

Massachusetts, which holds eleventh place in the list of forty-eight States and the District of Columbia, leads the rest of the New England group in total registrations, with 89,133, a gain of 12,301 vehicles, or 16 per cent over 1914.

Connecticut's Increase Large

The remaining five States are much smaller in registration, Connecticut, with 38,950 vehicles, adding 12,732, or more than Massachusetts gained during the year, being 49 per cent over Connecticut's 1914 total.

Maine ranks third with 18,600, a gain of 4300 machines, or 30 per cent.

Rhode Island is fourth with a total of 16,362, an increase of 4031, or 33 per cent over 1914.

Vermont is fifth with 11,499 cars and trucks, a gain of 3886, or 51 per cent, the highest percentage gain of the New England States.

Last, but not far behind, comes New Hampshire with its total of 10,819, representing 2081, or 24 per cent, more cars and trucks than in 1914.

Studying the registration statistics, we find a steady, consistent growth recorded from year to year in the New England States, the total for 1912 being 94,434 cars and trucks in use there as contrasted with the 76,488 reported at the end of 1911. The following year 22,969 more people bought cars or trucks, pushing the registration total up to 117,403, and in 1914 this increased to 146,032, in 1915 reaching an aggregate of 185,363. It will be seen from a comparison of the yearly increases in the number of registrations that these grew larger almost in direct proportion year by year, and it is also evident that the increases of the individual States have been usually in proportion to the total registration in each.

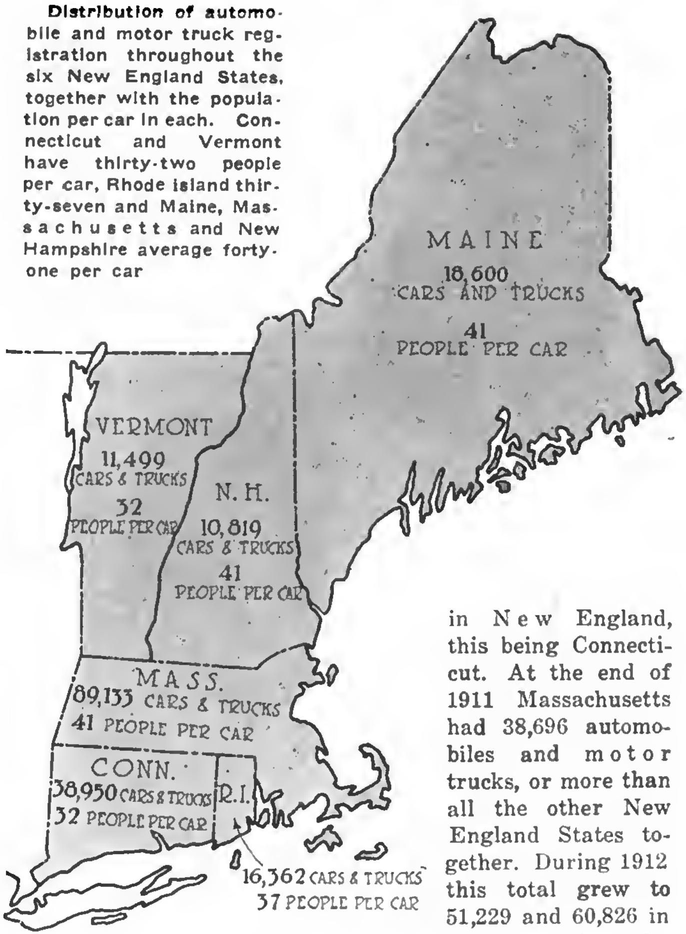
30 Manufacturers

Industrial statistics show that there are thirty manufacturing establishments in three of the New England States, Massachusetts, Connecticut and Rhode Island, which are producing automobiles, commercial vehicles and motors. There are twelve car makers, fifteen truck builders and five motor manufacturers, several of these being included under more than one heading, which explains the apparent discrepancy in the total.

2812 Dealers, Garages, Etc.

Similarly, there are 2812 automobile establishments in New England besides the manufacturing plants mentioned. Of these, dealers are represented to the extent of 1349, garages constitute 1580, repair shops 658, supply dealers 122 and charging stations 133. The same explanation as that given in the preceding paragraph serves to reconcile these figures with the total.

There are nearly 10,000 commercial motor vehicles in the Bay State, which has over twice as many as its nearest rival in New England, this being Connecticut. At the end of 1911 Massachusetts had 38,696 automobiles and motor trucks, or more than all the other New England States together. During 1912 this total grew to 51,229 and 60,826 in 1913, passing the 75,000 mark in 1914, the commonwealth having registered 76,832 motor vehicles. In the five years from 1911 to 1915, when 89,133 represented the total number of cars and trucks in the Bay State, 50,437 machines were added to its records. Illustrating the growing recognition of Massachusetts as a tourists' paradise, there were 13,500 non-resident car owners registered in the State in 1915 as compared with 7150 in 1914, only 920 in 1913 and 858 in 1912. Fees of various kinds paid by automobile and motor truck owners, dealers, chauffeurs, etc., passed the $1,000,000 mark last year, attaining a total of $1,205,420.19, as compared with $925,964.75 in 1914, a gain of $279,455.44.



Distribution of automobile and motor truck registration throughout the six New England States, together with the population per car in each. Connecticut and Vermont have thirty-two people per car, Rhode Island thirty-seven and Maine, Massachusetts and New Hampshire average forty-one per car

CAR AND TRUCK REGISTRATIONS IN THE NEW ENGLAND STATES SINCE 1911 WITH DUPLICATES ELIMINATED

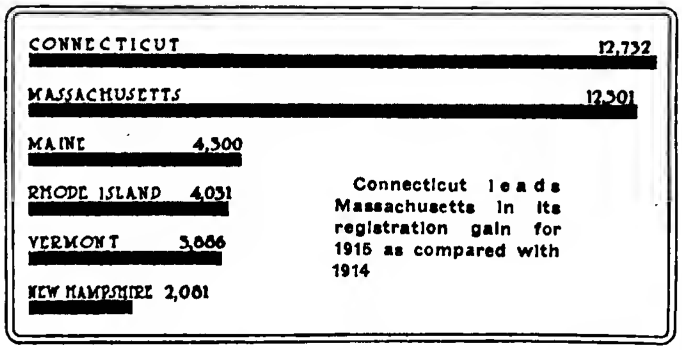
Massachusetts Still Leads

Accepting the latest census bureau estimate of 3,690,748 as the population of Massachusetts at the beginning of 1916, the Bay State has forty-one persons for each car and truck registered, allowing for all duplication.

Of great importance in the pioneer days of the automobile industry as the home of many manufacturing activities, Massachusetts is still a factor, having seven automobile establishments, ten motor truck plants and two motor manufacturers, according to *The Automobile Trade Directory.* In addition, a considerable percentage of the leading accessory manufacturers are located in this State.

Massachusetts has 1258 dealers, garages, repair shops, supply dealers and charging stations, there being 582 dealers' establishments, over twice as many as in Connecticut, which is in turn far ahead of the other New England States. The Bay State's total of 724 garages is nearly as many as all the others combined, while its 267 repair shops, sixty-six supply dealers and seventy-four charging stations are in each instance more than twice as many as any of the other States in the group can boast.

Connecticut registered 38,950 cars and trucks in 1915, or



Connecticut leads Massachusetts in its registration gain for 1915 as compared with 1914

over 20,000 more than any State in this territory with the exception of Massachusetts.

The Nutmeg State's increase in registration during 1915 was 12,732 cars and trucks, or 49 per cent, being 431 more than that of Massachusetts during the same period. In 1911 there were only 13,994 motor vehicles in Connecticut, this number increasing to 17,950 the following year and to 23,263 in 1913. At the end of 1914 the records showed 26,218 machines in use, the increase in registration for 1915 being 508 more than the gains made during the preceding three years combined. As compared with 1911, the 1915 statistics show an increase of 24,956 cars and trucks.

In respect to the number of trucks registered Connecticut is far ahead of all the other New England States except Massachusetts, having nearly 5000 in use.

Has Nine Manufacturers

Crediting Connecticut with 1,234,031 population, there are thirty-two persons to each car or truck in the State, this being the lowest number being shown by any of the New England States, an honor which is shared with Vermont. No statistics are available in regard to non-resident registrations in Connecticut.

There are five automobile manufacturers located in the Nutmeg State, which also has four motor truck builders and two motor manufacturers, although the total for the State is only nine, owing to the fact that some establishments are counted under more than one heading. There are 527 establishments in Connecticut included under the classifications of dealers, garages, repair shops, supply dealers and charging stations. This total is made up of 287 dealers, 220 garages, 120 repair shops, 33 supply dealers and 22 charging stations, many of these being counted under two or more heads so that they apparently do not agree with the total.

Connecticut's fees increased $136,619.85 in 1915, the amount received being $544,625.81, as compared with $408,005.96 in 1914.

Maine in Third Place

Maine's increase of 4300 cars and trucks in 1915 was 269 greater than the gain of 4031 made by Rhode Island. Thus Maine shows a 30 per cent increase in registration as compared with the 1914 total of 14,300, while on its estimated population of 770,064 for Jan. 1, 1916, it has a population-to-car ratio of 41. Of the total registration approximately 1000 are commercial vehicles. Maine's fees for 1915 were $13,865.12 less than those of New Hampshire, amounting to $268,412 as compared with $282,277.12. Yet the gain over the 1914 receipts of Maine's registration office was $112,726, or over 72 per cent.

In 1911 Maine's total registration was 10,045. In 1912 a new law went into effect shortly before the automobile census was made so that there were only a part of the cars in the

Rhode Island	1,000	288	**	**
Vermont	100	448	643	**
Total	3,108	1,672	9,653	16,966

*Includes re-registration. These are not included in other years.
**No record.

State on record. The 10,570 machines reported for 1913 seem to credit the State with only a small gain but it must be remembered that the 1911 figures include numerous duplicate registrations, no record of these being available at that time. In 1914 Maine's total had reached 14,300 and by the end of 1915 it was 18,600, a gain of 8555 in five years.

Maine has no manufacturers of automobiles, motor trucks, or motors, but it boasts of 354 dealers, garages, repair shops, supply dealers and charging stations. There are 115 dealers, only a few less than Vermont and a few more than Rhode Island, but the 217 garages rank Maine close behind Connecticut. There are sixty-two repair shops, five supply dealers and fourteen charging stations.

Rhode Island Ranks Fourth

On a population basis of 608,540 Rhode Island, the smallest State in the country, has thirty-seven persons to each motor vehicle. Of the total registration, over 1500 are motor trucks while the fees received by the registration department last year were $208,498, an increase of $51,478 over the $157,020 taken in during 1914.

The number of motor vehicles in Rhode Island has increased almost proportionately each year, varying from 6017 in 1911 and 7565 the following year to 9894 in 1913, growing to 12,331 in 1914 and again to 16,362 last year, the total increase for the five years being 10,345 cars and trucks, or nearly 200 per cent as compared with the 1911 registration total.

Although there are no automobile manufacturers in Rhode Island, this State is the home of one motor truck maker and one motor-manufacturing concern. There are only 209 dealers, garages and similar establishments, this total being smaller than that of any of the other New England States except Vermont which has 197. In so small a territory naturally comparatively few dealers are required, there being eighty-five in the State. Garages number 110, there are seventy repair shops, eleven supply dealers and nine charging stations.

Vermont Stands Fifth

Although New Hampshire had 1242 more cars registered in 1911 than Vermont, in 1915 the latter State managed to forge to the front, its total of 11,499 cars and trucks being 680 in excess of the 10,819 which New Hampshire was able to muster. Vermont's increase over its 1914 total of 7613 was 3886, or 51 per cent, and on a population basis of 363,075 its population-to-car ratio was 32, this State sharing with Connecticut the place of honor in this respect among the New England group. Vermont's increase in motor vehicle registration during the five years from 1911 to 1915 was 8252, or over 200 per cent.

Few Trucks in Vermont

Only about 350 motor trucks are in use in Vermont and the receipts of the State motor vehicle registration department during 1915 amounted to $218,479.85, an increase of $64,212.94 as compared with $154,266.91 collected in the preceding year.

Like that of the other States, Vermont's annual gain in registrations has been fairly constant, the number of cars and trucks recorded each year varying from 3247 in 1911 and 4183 a year later, 5430 in 1913 and 7613 in 1914, to 11,499 last year.

There are no car, truck or motor manufacturing establishments in Vermont but there are 197 dealers, garages, etc., many of whom necessarily are counted more than once since they operate establishments requiring classification under more than one heading. Thus there are 121 dealers, 125 garages, fifty-four repair shops, four supply dealers and three charging stations.

New Hampshire in Sixth Position

Although ranking below Vermont on the basis of car and truck registrations in 1915, New Hampshire is only 680 behind, having 10,819 motor vehicles as compared with 8738 at the close of 1914, a gain of 2081 machines, or 24 per cent. Like Maine and Massachusetts, New Hampshire has forty-one persons for each car and truck registered, its population on Jan. 1, 1916, being estimated at 441,545. There are nearly 1000 commercial vehicles included among the registrations and fees for 1915, covering passenger cars, trucks, dealers, chauffeurs, etc., amounted to $282,277.12, or $82,274.62 over the 1914 total of $200,002.50.

In 1911 New Hampshire had 4489 motor vehicles, increasing to 5764 in 1912, and during the following year to 7420, the 1914 registration amounting to 8738 and the 1915 total to 10,819. Thus the increase for the five years since 1911 was 6330 cars and trucks, or over 100 per cent.

Dealers, garages, repair shops, etc., in New Hampshire number 267, there being 159 dealers, 184 garages, seventy-six repair shops, three supply dealers and eleven charging stations. It will be noted that all of these figures with the exception of the number of supply dealers are considerably in excess of those for Vermont, which has 680 more cars registered than New Hampshire.

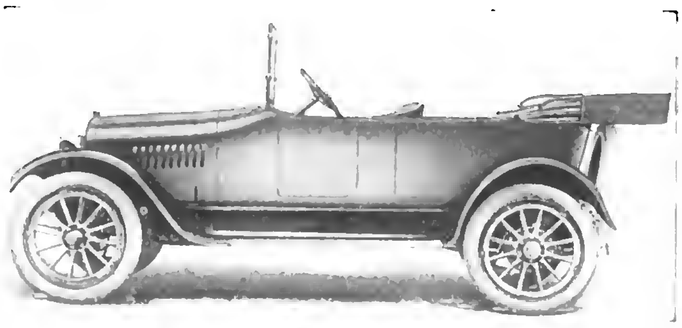
Dixie Flyer Is New Car

THE Louisville Automobile Show marked the first public appearance of the Dixie Flyer, made by the Dixie Motor Car Co. of this city. The new car is to sell for $775.

The Dixie Flyer has a four-cylinder unit power plant with floating rear axle and 112-in. wheelbase, using the Dyneto electric system. The body is a yacht type finished in bottle green, the high crowned fenders and radiators are black enameled and wheels are finished in a light natural wood stain.

The instrument board is covered with buffed leather and outlined with raised aluminum binding, the interior of the doors are covered with the same heavy grade of upholstering material as the cushions, and the floors and toe board are covered with deep piled carpet of a tan-olive shade blending into the general color scheme. It is close fitting and neatly and durably bound around the pedal and lever openings.

The Dixie Flyer is furnished with complete equipment, including one-man top, quick detachable side curtains, etc., and a full complement of tools.



Four-cylinder Dixie Flyer listing at $775

Lest We Forget

New England's Pioneers Did Much to Put the Industry Where It Is Today—Home of Mechanics Who Were Fascinated by Problems of Road Locomotion

IT is but natural that New England, the home of the best mechanics in the world, should have had its share in the development of the automobile industry. New England's entire atmosphere breeds accurate workmanship and mechanical virility which has been an influential factor in the development of more than one of the country's leading manufacturing arts.

The fascinating problems of motion, particularly as applied to self-propelled vehicles proved irresistible to New England's mechanical mind and in many a back yard, men, whose daily pursuits were in other fields, labored after hours and late into the night on vehicles which have left their stamp on the industry as it is to-day. Even at the time of the Civil War the experiments of Roper in and around Boston attracted attention and the story of Roper is the story of many others who helped to solve the big initial problems of the horseless carriage.

Here in the atmosphere of the forge and machine shop where the raw materials of the world are turned into finished products, the mechanical skill of men accustomed to the loom and machines of precision and complicated motion soon began to clear a way through the jungle of difficulties in the way of road locomotion. It was but natural then that steam, the best known motive power, should be first employed and the necessity for a light-weight steam vehicle soon brought to light developments which are important factors in steam plants to-day. For example James H. Bullard, Springfield, Mass., built in 1885 a cylindrical boiler with horizontal fire tubes.

Early Steam Vehicles

Fairly successful steam cars were constructed in New England as far back as 1893, when C. L. Simmonds, Lynn, Mass., had one operating in the streets, and in the years previous to 1898 the steam car of George E. Whitney, the forerunner of the Stanley, was a common sight in Charles River Park, Boston. Then later, when the internal combustion engine was developed to a higher point, men like C. E. Duryea, H. P. Maxim, H. W. Alden and others were not lacking to take up this phase and bring it rapidly to the front.

Automobile activity has shifted to the Middle West with Michigan and Indiana as our leading manufacturing States, and the part that New England played in the development of the motor car is apt to be forgotten. Memory should be refreshed of the giant's part borne by the country of the Pilgrims and the Puritans in building an industry which typifies modern science, because that part is immensely important in that many of the leaders of the industry to-day found their automobile engineering birthplace in New England.

The Electric Vehicle, Pope, Knox, Columbia, Duryea, and Locomobile companies have been the schools in which many of the automobile engineers of world-wide renown to-day received the experience and training which has made them preeminent. Some are still in New England, others have followed the trend toward the Middle West and are now established closer to the heart of the industry to-day, and yet there was a time when the little group of manufacturers in the six New England States included in their ranks a large percentage of the automobile engineers of this country.

Turn back to 1906: Ten years ago, the membership list of the Society of Automobile Engineers included eight New England engineers. These were H. W. Alden, Harry A. Knox, Hiram P. Maxim, W. J. P. Moore, B. Morgan, A. L. Riker, Henry Souther and A. C. Schultz. These pioneers, most of whom have made automobile history both in New England and in other parts of the country, are representative of the spirit of New England, a decade and more ago.

To-day the New England membership of the S. A. E. is 140, and since the society is growing steadily there is no doubt that this will increase annually, but now that the pioneers have cleared the way and put this giant industry in the position it occupies to-day, it is well that in giving honor to New England for the part it rendered in the early days, that credit also should be extended when the automobile had to combat the popular prejudice of the day, not to mention adverse legislature and adverse traction interests.

Beginnings of the Nineties

But far back of the first days of the history of the S. A. E. some of the pioneers mentioned were at work. H. W. Alden and Hiram Percy Maxim were associated in the American Projectile Co., and in the fall of 1894, when Mr. Maxim started experimenting in Lynn, Mass., with his three-cylinder tricycle, Mr. Alden was associated with him, making most of the drawings for the odd vehicle at night. This tricycle was run over the roads of Lynn and vicinity in 1895. Mr. Alden migrated soon afterward to the Pope Mfg. Co., Hartford, following Mr. Maxim, these two being associated with Hayden Eames in the opening of an experimental motor car department under the direction of the Pope Mfg. Co.

Mr. Alden went with the Electric Vehicle Co., Hartford, in 1902 and remained until 1905. This concern was another great developer of automobile engineers, having been the school in which more than one now well-known engineer received his early training in the automobile business. Mr. Alden remained with the Electric Vehicle Co. until June, 1905, and then returned to the Pope Mfg. Co., where he developed the commercial car department, building several trucks with two-cylinder, horizontal, opposed motors. In April, 1906, Mr. Alden left New England, the scene of his early endeavors, and went with the Timken company Detroit, where he has been ever since.

An 1896 Four-Cylinder

A story of New England automobile engineers cannot be told without mentioning Harry A. Knox, who in 1896, while attending the Springfield Industrial Institute, designed and built a four-cylinder-opposed, four-cycle, horizontal engine, and later in connection with A. H. Overman, president of the Overman Bicycle Co., Chicopee Falls, Mass., made arrangements to develop an automobile with this motor. The activities of Mr. Knox also extended to the Duryea Co., Springfield, Mass., as while working at the Springfield Industrial Institute he had been employed on the first ten Duryea cars that were ever built for sale. He remained with the Overman Bicycle Co. until 1908, during which time several vehicles were built. The last car build at the Overman works was the foundation of the afterward famous Knox car. This was a four-wheel runabout weighing about 1000 lb. and having a 90-in. wheelbase. E. A. Cutler, Springfield, Mass., became interested in the car and associated himself with Mr. Knox in 1898, forming the Knox Auto Co.

In 1899, in his engineering capacity for the Knox company, Mr. Knox built about twelve or fifteen cars, and 1900 over 100 of the three-wheel Knox runabouts were sold. Chas. Y. Knight, inventor of the Knight engine, earned the right to be mentioned in a New England engineering story by buying one of the first of these cars. Mr. Knox sold out his interest and resigned as vice-president and general manager of the Knox Automobile Co. in 1904, forming the Knox Motor Truck Co. of Springfield, Mass. The previous Knox company forced him to abandon the name Knox in connection with his manuracturing activities and the company was renamed the Atlas Motor Car Co. with Mr. Knox president and general manager.

Knox Used Worm Drive

The Atlas Co. built several two-cycle, two-cylinder runabouts in 1908 and in 1910 and 1911 a considerable number of two-cylinder two-cycle taxicabs. In 1912 Mr. Knox designed and built a large touring car with worm drive equipped with the Atlas-Knight engine, and in this year plans were made to build a quantity of these cars, but owing to inability to obtain engines the scheme fell through.

The business of the Atlas Motor Car Co. was closed in the Spring of 1913, and at that time Mr. Knox joined the ranks of those who had migrated from New England and located with the Lyons Atlas Co., Indianapolis, Ind.

Hiram Percy Maxim, inventor of the Maxim silencer and president of the company which manufactures this device, is one of the early New England automobile engineers. As has been indicated, Mr. Maxim and Mr. Alden were connected in the development of the three-cylinder tricycle in 1894 and 1895 and under Hayden Eames of the Pope Mfg. Co. this was actively manufactured in Hartford. Col. George Pope, chairman of the New York Show Committee for many years, took his first ride in a Columbia automobile with Mr. Maxim in October, 1895, and in 1896 Mr. Maxim was interested in the building of Columbia electric cars, which were sold abroad and in this country for $3,000 each. In 1898 and 1899 a single-cylinder four-cycle engine was developed by Mr. Maxim for the Columbia Co., and this machine proved to be very successful, making good records in many of the endurance runs such as the Automobile Club of America run from New York to Buffalo, 1903. This machine was the well-known Columbia Mark VIII. In 1903 some of the two-cylinder Columbias were developed. Mr. Maxim still remains a New England engineer, although his activities are now in connection with the silencer and not with the motor vehicle.

Tried Electric Tricycle

Another engineer whose early associations were in and around New York and then in New England and who has remained in that part of the country is A. L. Riker, now a member of the Naval Consulting Board under Secretary Daniels, and chief engineer and vice-president Locomobile Company. Mr. Riker's connection with the automobile industry began with his application of a storage battery to an automobile in 1890. This was a tricycle known as the Coventry rotary. He sold his first electric motor car to J. R. Whiting in 1897. Mr. Riker's activities were with the Riker Motor Vehicle Co. in Elizabethport, N. J., until 1902 when he went with the Locomobile Co., Bridgeport, Conn. His call to the Locomobile Co. in 1902 was for the purpose of developing a gasoline car. Mr. Riker was the first president of the S. A. E.

New England activities in the S. A. E. have never been more strongly represented than by Henry Souther, whose work as chairman of the Standards Committee will long be remembered. Mr. Souther earns the right to be called a New England pioneer due to his connections with the Pope Mfg. Co. in 1895 where he was associated under Hayden Eames with Messrs. Maxim and Alden. Mr. Souther was sent abroad in 1895 by the Pope company, and in 1899 left their employ and took up the work of consulting engineer, during which time he did considerable work for the Locomobile, Knox, Duryea and Columbia companies. Mr. Suther also joined the movement away from the New England States and has now taken up his work as vice-president and general manager of the Ferro Machine & Foundry Co., Cleveland Ohio.

If the development of automobile engineering in New England is to be studied, the Stanley automobile made by the Stanley brothers, F. E. and F. O., must be cited as one of the landmarks. The first Stanley automobile ever put on the road was in the Spring of 1897. The Stanley brothers are from Lewiston, Me., and it was in this town in 1887 that they received their first inspiration to build steam cars. Their experiments were continued for ten years, the first car being built, as stated, in 1897. In 1899 John Brisben Walker, a magazine publisher, entered the ranks of the New England automobile engineers by purchasing the Stanley works in 1899, but afterward sold the plant at Newton to a Mr. Barber. After this, the Stanley brothers bought back the Newton plant and in 1902 again resumed the manufacture of cars which has been continued to date.

Zenith Reached in 1909

The zenith of automobile manufacturing in New England was reached in 1909 and 1910. Big companies like Alco, Pope-Hartford, Stevens-Duryea and others were then actively making cars which possessed national reputations for excellence. In addition, large numbers of concerns building various accessories began to enter the business, and since then this field has been growing rapidly. As a consequence, from 1910 on the ranks of the New England automobile engineers have been steadily augmented, but in the infancy of the automobile business the men connected with the industry were with the automobile manufacturing concerns as indicated by the representative men mentioned together with many others such as H. Vanderbeek, H. S. Baldwin, who were on the engineering staff of the company which was named successively Pope Mfg. Co., motor carriage department, Columbia & Electric Vehicle Co., and Electric Vehicle Co.

Although in numbers the factories that produce automobiles in New England are not as great as a decade ago, it does not mean that the automobile industry has ceased to depend on that part of the country. In fact, the New England engineer is a very influential factor to-day in the automobile industry. His development of tools, machinery, fabrics and other manufactured products makes him a very necessary link in the chain which connects the finished automobile to the raw material. New England's great population of trained mechanics and engineers have every reason for appreciating the automobile, their environment, training and inborn mechanical ability demand it.

Various causes led to the movement of many of the early New England engineers to other cities, especially the abandonment of the automobile business by some of the concerns such as the American Locomotive Co., when men like B. D. Gray, who was chief engineer for that concern and who is now vice-president and manager of the Hess-Bright Mfg. Co., left for other fields.

The shifting of the industry to the westward has caused the shifting of men, but the effects of the impetus given by the New England engineers will not cease to be felt for a century.

New England News of '99

Many Curious Ideas Shown in Paragraphs From "The Motor Vehicle Review" of 1899 and 1900—Liquid Air Automobiles Expected—Mile Record 1.34 4-5—Plans of First Boston Show

The First Doctor Automobilst

SPRINGFIELD, MASS., Nov. 6, 1899—Dr. A. O. Squier, of this city is the first Western Massachusetts physician to discard the horse and buggy for the motor vehicle, and now his fellow-physicians are watching him with not little curiosity, slightly tinged with envy.

Electric Does 25 Miles on One Charge

BOSTON, Sept. 22, 1899—One of the chief difficulties that the manufacturer of electric motor carriages has had to contend against up to the present time is an inability to produce a carriage that will run for any considerable distance without recharging the storage batteries. The extreme limit of distance thus far scored is 25 miles.

Police Use Automobiles

BOSTON, Sept. 22, 1899—Mayor Quincy's experiment in the use of motor vehicles for the chiefs of city departments is proving successful. Only one carriage has been tried as yet, but it has been stated that it does the work of three horses. It is used for many business trips around town for which a horse with wagon was formerly needed. The motor vehicle does not have to rest, as a horse does. Mayor Quincy has ridden in it several times.

Liquid Air Automobile Co. Formed

BOSTON, Sept. 7, 1899—The Liquid Air, Power & Automobile Co., Boston, has purchased a five-story and basement brick factory in Cambridge, to manufacture liquid air for automobiles and other machines run by that power. The patents owned by that company cover processes which are claimed to reduce the cost of manufacture to a minimum, and to enable the practical application of liquid air energy as power for driving all sorts of machinery. The company's automobiles, run by this power, weigh less than 300 lb., and would make a trip of 100 miles at an expense of only a few cents.

Mile Road Record, 1.34 4/5

BROCKTON, MASS., Oct. 17, 1899—The fastest mile ever ridden over a highway in a vehicle was made yesterday afternoon on the State highway at Whitman, by the motor vehicle built and owned by the Marsh brothers of this city. The time for a warming up mile was made in 1 min., 51 and 1/5 sec., thus establishing a new 1-mile motor vehicle record for the world. Mr. Marsh opened the throttle suddenly and the vehicle, with its 350 lb. of weight, the lightest in existence at that, shot up the hill like a bolt of lightning. Immediately after this performance a mile was made in 1 min. 34 and 4/5 sec.

Covered 150 Miles in 12 Hours

WORCESTER, MASS., Aug. 25, 1900—The first two-seated motor vehicle has made its appearance here. It is the property of J. W. Bigelow, and was brought here from the Locomobile factory. A trip of 150 miles was made in 12 hr.

Records Cause Wonder

PROVIDENCE, R. I., Feb. 14, 1900—Motor vehicles are coming into wider use in this city among society people and business men, and are rapidly supplanting the fractious horse. Three years ago, when these vehicles first appeared on the streets on their way to Narragansett Park, where the first big race was to be held, they were a novelty and attracted wide attention. The records made by the electric and gasoline carriages were subjects of wondering comment, and their cost, stated at upward of $1,000 each, seemed prohibitive.

Boston to Have Automobile Show

BOSTON, Dec. 8, 1900—There is a rumor that Boston will witness a motor vehicle exhibition in Mechanics' Building early next spring. The effort to bring about the holding of such an exhibit is being made by a large number of men who are not interested in the motor vehicle for monetary gain, but rather for personal pleasure and comfort.

University Automobile Clubs in 1900

NEW HAVEN, CONN., Nov. 24, 1900—Motor vehicle clubs composed of students of the various universities are now being formed. A meeting of the Yale students to organize will be held in the near future. Harvard motorists have also been asked to organize.

Status of Automobile

WORCESTER, MASS., Nov. 27, 1900—Steps have been taken in court in this city to determine the legality of motor cycles and motor vehicles as vehicles. Efforts will be taken to secure recognition for motor vehicles on a footing with the regular horse carriage. The question of liability for runaway accidents is what is scaring motorists of Worcester and the State. It is well known that the horseless carriage is almost everywhere causing accidents beyond city limits by reckless and fast driving. It is claimed that the users of motor vehicles are liable for all damages caused on the road, inasmuch as the motor vehicle has not legal license to use highways.

Good Roads Closed to Automobiles

BOSTON, Feb. 15, 1900—The motor vehicle has created a storm in this city. These vehicles are prohibited on most of the good roads in and around this city. If you engage an electric cab for a run out to Brookline you will notice that the driver stops on entering Brookline. He gets from his seat and goes to the hack of the cab. There he attaches a black tag with the license number of the cab, printed in white thereon. The figures are large. They are fully 2 in. high.

Must Stay Outside Cemetery

BOSTON, Feb. 15, 1900—A notice has recently been posted at the main entrance to Forest Hills Cemetery, this city, reading "Automobiles are not allowed in this cemetery." As stated by the secretary of the cemetery company, "We cannot afford to run the risk of having automobiles cause trouble in the cemetery. We have agreed with many of the lot owners that we shall take perpetual care of their lots, and make good any damage to them. Some of the protected property includes valuable monuments and other marble work of value, and the risk of having some horse frightened by an automobile is more than we care to take. If an automobile should swoop suddenly down on a funeral procession there might be a regular stampede."

First Accident Suit in Boston

BOSTON, June 6, 1900—The first suit growing out of an accident caused by a motor vehicle came up for trial in the U. S. circuit court to-day. The plaintiff seeks damages of $25,000, alleges that the accident was due to the negligent, careless and unskillful manner in which the vehicle was managed and controlled. The defense is that the plaintiff walked against the machine.

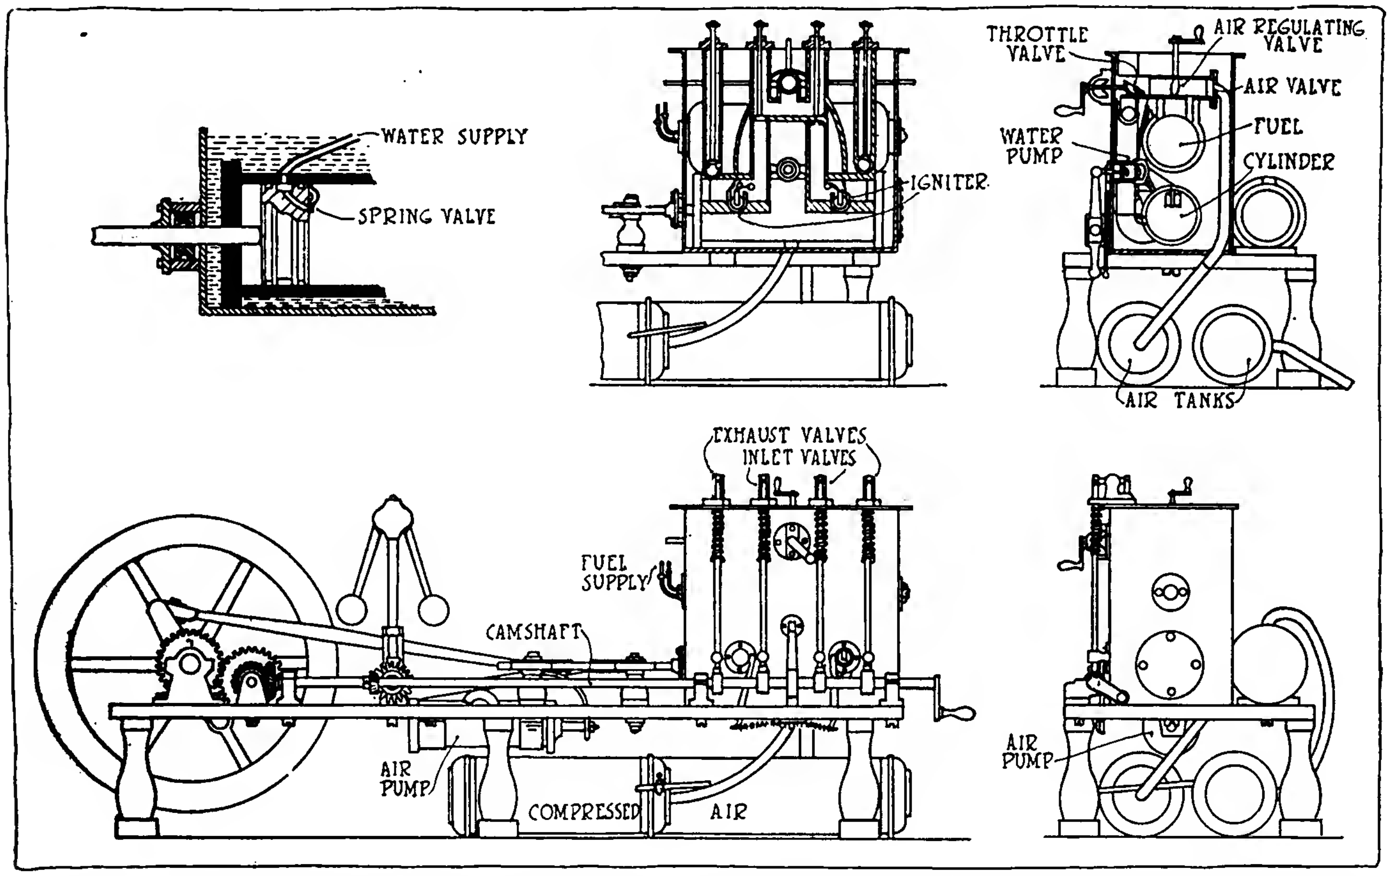
The History of the American Automobile Industry—19

Stuart Perry an Important Man in Early Development—Water Used as Lubricant—Tried Compressed Air Starting System—Grasped All Essentials of the Gasoline Engine

By David Beecroft

IN developing the internal combustion engine too great credit cannot be given to the work of Stuart Perry of New York, whose patents, issued in 1844 and 1846, showed a practical engine. Perry's accomplishments were outlined in last week's issue and we are fortunate in being able to illustrate his motor this week, the illustrations being taken from his patent papers. Unfortunately we cannot show a complete cross-section of the engine, but in the upper left is a section showing one end of the cylinder with a double-acting piston; that is, an explosion taking place at either side of the piston the same as pressure is applied to each side of a piston in a steam engine.

Perry's engine was a vertical type with valves located in the cylinder head, with waterjacket for the cylinder walls, cylinder head and valve parts, but not resembling the present-day engine very much, but rather being fashioned after steam practice of 70 years ago. As stated last week, Perry used an air starter and, in fact, his patent drawings show no effort of attaching a starting crank,



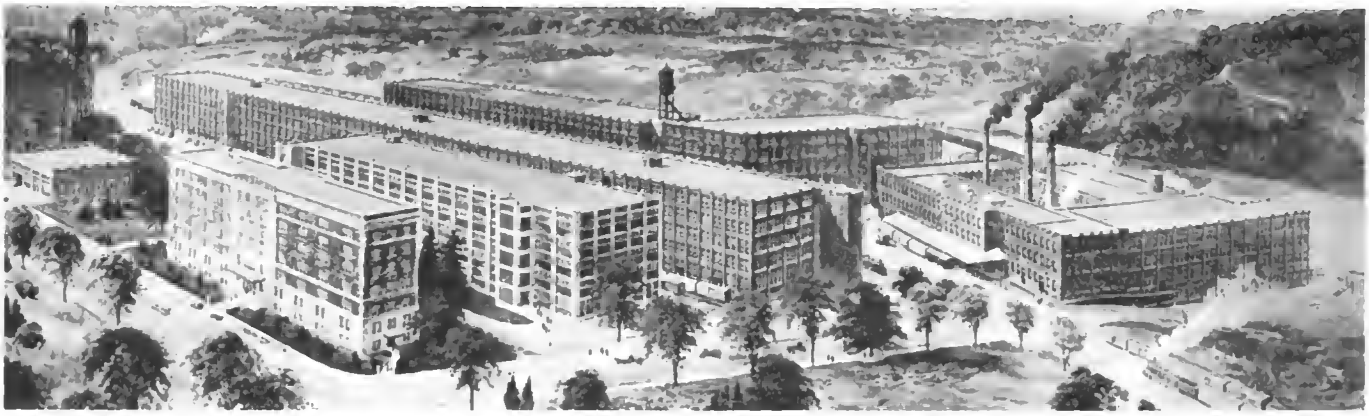
Details of the internal combustion motor of Stuart Perry, New York City. This was invented in 1844 and 1846. The upper left illustration shows how he lubricated the piston and cylinder by water. The other illustrations show his system of air-starting, and the small handle on the external camshaft was set by hand to start. The upper right illustration shows how Perry used a throttle valve to regulate the flow of mixture with the cylinder. He also used a regulating valve to control the flow of air with the object of securing a satisfactory mixture. Perry's motor was a double-acting type; that is, an explosion took place at either side of the piston. It was entirely water-jacketed, used tube ignition and had intake and exhaust valves operated from an external camshaft.

rather there is a miniature crank attached to the external camshaft, which crank was used to put the camshaft in the proper position for starting; that is, to open the intake valve to admit the explosive mixture when it was ready and then to close the valve and revolve the cover on the platinum ignition tube so as to let the heat of the tube explode the mixture.

As several of the illustrations will show, Perry used two large air tanks, one of which was connected with an air pump, either driven by hand or from the motor. The usual valves were employed in the air system for conducting the air into the cylinder for starting purposes.

Perry relied entirely on water to lubricate the cylinder and piston. The upper left illustration showing a section of the piston discloses how there was a water supply pipe leading through the cylinder wall and registering with a water groove in the piston. This water pipe registered with the groove when the piston was at the end of the stroke. There was a double-acting water pump shown in the upper right illustration which was connected with the water supply pipe leading to the piston so that when the piston registered with the pipe as illustrated, a stroke of the pump plunger delivered water into the piston groove. This groove connected with a spring valve in the piston so that the water pressure opening this valve permitted a part of the water supply to be injected into the cylinder. This supply was considered sufficient not only to aid in lubrication, but also to add its expansive force. In addition the piston rod was lubricated by a water packing gland. At either side of the water groove in the piston were packing arrangements to retain the water in the groove.

To start his motor Perry realized the necessity of heat to vaporize the spirits of turpentine used as a fuel and it was doubtless this difficulty of starting that led him to use the compressed air, which assisted the explosive power of the mixture in starting. He did not use a carbureter, as we understand it to-day, but employed a retort into which the spirits of turpentine was fed. This retort was waterjacketed and it was necessary to heat the water by external means to a point where the turpentine was converted into a gas. When the necessary mixture was obtained the camshaft was turned by hand to the proper position to open the intake valve and at the same time closing the exhaust. The mixture then filled the cylinder and a further turn of the camshaft closed the intake valve and uncovered the ignition tube. After the first explosion it was expected that the regular cycles would continue the explosions, the camshaft being driven from the crankshaft after its first setting by hand.



Two New England factories. The Fisk Rubber Co., Chicopee Falls, Mass., and below, the American Chain Co., Bridgeport, Conn.

Floating Bush Bearings in Live Rear Axles for Trucks

A British Opinion on Commercial Vehicle Design

IN a paper presented to the Institution of Automobile Engineers and discussed at a recent meeting of this society, George W. Watson, a member of the council, reviews all construction features in live axles for commercial vehicles with critical comment and illustrations. The usual distinctions between floating, semi-floating and non-floating axles, as well as between "solid forging" and built-up axles, are made the basis for the division of the subject and the cast-steel wheel is the type contemplated as used. Among the statements made by the author, and in the discussion by members of the British society, those of greatest interest to the American industry are quoted in substance in the following. The remarks referring to floating bushes for wheel bearings in heavy vehicles are perhaps specially interesting, as this system was proposed for bicycles many years ago in this country—somewhere about the year 1899—on the plea of reducing friction and equalizing wear of the stationary member of a bearing almost or fully as much as ball bearings, but has not been employed extensively here for motor vehicles.

For vehicles intended for use on paved or good macadam roads the author advocates worm drive for all axles up to six-ton limit of axle weight, but for heavier and slower vehicles he considers the double-reduction type to be the better, particularly if the differential is mounted on the crown wheel shaft and the final drive taken through two pairs of spur gears, as in the construction shown in the accompanying illustration. This construction is on the whole one which he considers very favorably, also in other details.

In some cases, where ample ground clearance is wanted, the worm drive may not be acceptable, he holds, "because it is not practicable to make a worm wheel as small in diameter, for a given gear ratio and load, as may be given to the final gear wheel of a double reduction axle."

It is mentioned as an objection to the spur gear type of differential that there is double the amount of backlash, as compared with the bevel gear type, due to the aggregate clearances between bearings and gear teeth, and this he considers in time liable to become serious.

To make axle shafts and driving flanges in one piece is held to be bad practice, because the flanges are apt to be bent by rough handling in repair shops, and if the flange is subsequently bolted up tightly to the wheel, the shaft is liable to be badly stressed, causing serious fractures.

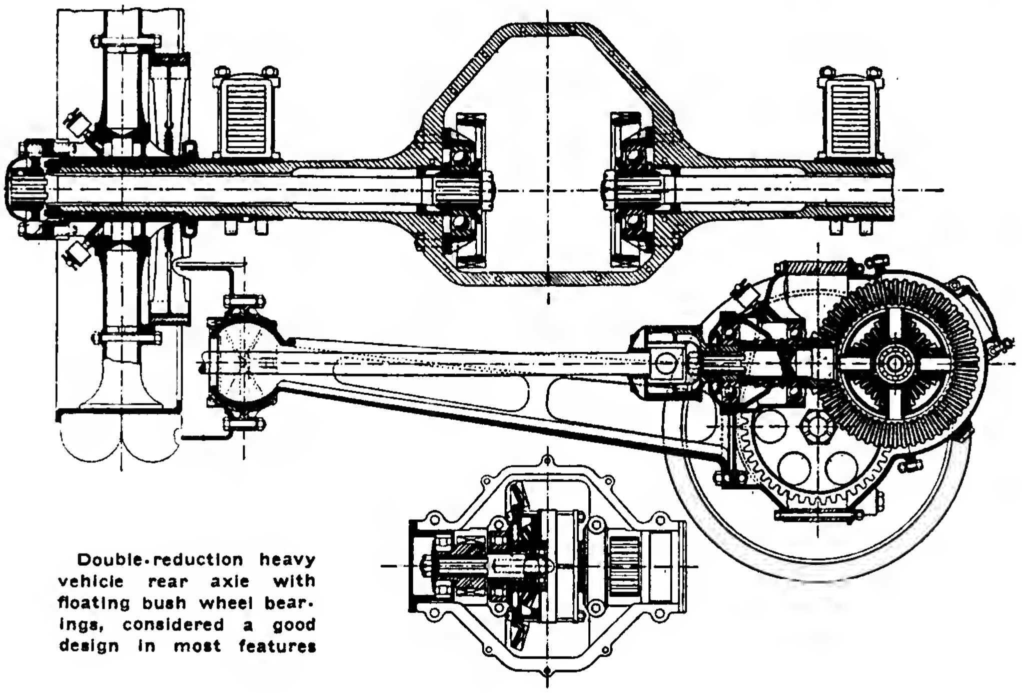
It has been proved that in the hubs of road wheels floating bushes are much better suited to the rough usage of commercial service than any tried form of roller or ball bearing. A wheel with floating bushes is easily and quickly replaced in the event of tire damage, and such a bush properly made and fitted offers very little more friction than a ball bearing hub of equal load capacity, except when starting from rest.

Both the external and the internal clearance should be greater for floating bushes than would be allowed for any ordinary bearing. The army specifications allow between 0.006 and 0.0136 of an inch for both outside and inside fits, and the normal diameters of the bush to which these limits refer are 3.5 and 4 in. With closer fits the lubrication becomes uncertain. The play noticed with the larger clearance, when the axle is jacked up, is more apparent than real, and it makes the removal of the wheel easier.

The distribution holes in floating bushes should be drilled along a helical line and spaced so as to carry grease (or heavy oil) to every bit of the axle and hub surfaces. The rubbing surfaces of both axle and hub should be ground and polished to secure the best results, and, if the hub is a casting, it is therefore advisable to force into it a steel liner by hydraulic pressure, with subsequent grinding of the bore. Care should be taken to remove thoroughly the metal particles that may be left in the oil passages after the grinding.

According to the author's experience it is not necessary to harden the wheel journals of an axle, provided the pressure caused by load and tractive resistance does not exceed 400 lb. per square inch between the axle and the floating bush.

In no part of an axle should end-thrust be left to take care



Double-reduction heavy vehicle rear axle with floating bush wheel bearings, considered a good design in most features of itself. Where it is not possible to fit a single or double thrust ball bearing, a floating washer of phosphor bronze not less than 5/16 in. thick should be provided, and it should be placed between steel surfaces that are ground, though not necessarily hardened. Casehardened thrust washers, particularly when used with floating bushes in wheel hubs, have an unfortunate habit of cracking.

Objects to Truss Bars

The truss rod or tie bar for any axle subject to great variations of the load is a source of weakness, because it cannot be adjusted to balance the stresses which are set up. The careless adjustment of a tie bar, to take all sag out of an axle when it is under full load, may lead to excessive bending stresses in the axle casing in the opposite direction when the load is removed. Generally, in practice, as has been shown with the army trucks in France, it is the tie rod which gives out first, but injury to the axle frequently follows. [No mention is made by the author of the use of suitable rebound checks to prevent the oscillation of the axle and transmit excess loads to the vehicle frame, although this expedient, if properly designed, may save as much material and weight in the axle as the use of a truss bar and is not subject to the objection mentioned against the latter.]

In the matter of lubrication of the axle, the author prefers to allow the free passage of oil from the central casing to the wheel journals, rather than to take constructive measures to prevent such leakage, provided only that steps are taken to drain the leakage away from wheels and brakes. One of the reasons for the preference is that drivers are more likely to give attention to the lubrication of the axle if they are not put to more trouble than that of dropping an occasional pint of oil into the central casing. He has also found it to be good practice to mill a broad flat on the top side of the wheel journals, when plain or floating bushings are fitted, as this flat facilitates the distribution of lubricant over the whole length of the bearing. All thrust washers should be provided with distribution paths, preferably in the form of eccentric grooves, with the throw of the eccentrics on the two sides arranged diametrically opposite; otherwise the washer may be so weakened that it will split along the groove. Cross or radial grooves invariably lead to breakage of the washer.

In the discussion of Mr. Watson's paper it was brought out that several members consider the matter of unsprung axle and wheel weight rather unimportant for trucks; that the forged axle is widely preferred to the cast one but is difficult to obtain in Great Britain—not only under war conditions; that internal-gear drives are considerably lighter than axles with double gear reduction, and that the preference for floating bushes over ball bearings in wheel hubs and for differentials, is not unanimous, as ball bearings have been proved reliable for the heaviest vehicles and their interchangeability is a highly appreciated feature.

Automobiles Save 32 Cents Per Mile in Road Supervision

IN these days of efficient and businesslike methods the government authorities do not intend to be outdone in these respects. An evidence of this is the report of cost data kept on three low-priced automobiles used in supervising work on the Washington-Atlanta Highway by the Office of Public Roads and Rural Engineering. E. W. James, chief of road maintenance in this department, states that, based on records kept since May 24, 1914, when the cars were put into service, through December, 1915, the cost of transportation per mile of road under supervision averages 20 cents per month. The only comparable cost figures for the use of livery horse vehicles for similar work give 52 cents per mile per month for transportation. The economy of the automobile in this work is emphasized by the large possible saving of time, and thereby money, developed by the field men of the office.

42.9 Miles per Day

Of the three cars in use, that having the lowest mileage to date has run an average of 28.4 miles per day, thirty days a month, since going into service. The highest mileage shows 42.9 miles per day for the same period.

As shown in the accompanying tabulation, the average cost per mile of all three cars since put into service was 4.13 cents, including a general overhauling on each.

In the first tabulation is given a summary of the miles run, total cost and cost per mile of each of the three cars during each month of 1915, together with the totals for the year, for the year 1914 and the grand totals including all costs since the cars were put into commission.

The second table gives the average cost of gasoline, oil, tires, storage, etc., on each car for the years 1914 and 1915, with the weighted averages for total operation costs during the entire term of service of the vehicles. In the last column of this tabulation is given the common average for all cars for the whole period.

Summary by Months of 1915 of Cost Data on Three Cars Used in Road Supervision

What Good Lighting Really Is*

Automobile Lighting Analyzed from the Lighting Viewpoint

By Emerson L. Clark

THE subject of good lighting is about contemporary with that of automobile engineering, both forming the two youngest branches of engineering work. Artificial lighting has been employed by man for many centuries; likewise man has for an equal period used wheeled vehicles to satisfy his transportation requirements. During the last 15 years transportation by wheeled vehicles has undergone a most extraordinary advance in the development of the automobile. During the same period advances have been made in illuminating engineering which are of comparable importance in the annals of lighting. Thus we see that two such diverse subjects as automobile engineering and illuminating engineering have a few points in common.

Notwithstanding the fact that much information of value in obtaining good lighting has been accumulated and classified, very little of this has been used to improve the lighting of the automobile. I have carefully examined the Transactions of the Illuminating Engineering Society for several years back and failed to find a single paper reporting a study of the lighting requirements of the automobile.

Good Light Essential

Automobile lighting is not merely a luxury—it is a necessity and upon its quality, its suitability, the safety of life and limb depend. Proper appreciation of the importance of the right kind of automobile lighting for preventing certain classes of common accidents is not now exhibited by many persons who should possess it. Good lighting in factories and industrial plants is recognized as being a powerful factor in the prevention of accidents. Statistical plots of the occurrence of accidents throughout the year show that the number of accidents varies directly with hours of darkness. As the days become shorter the number of accidents increase. Proper lighting of the automobile is even more important than the lighting of a factory because the automobile moves rapidly in the midst of other rapidly moving vehicles over all sorts of roads in various states of repair, past innumerable crossings which are always a potential source of accidents.

In to-day's *Plain Dealer* (Jan. 27) I read an account of a man who left his lodge meeting the night before and stepped in front of a swiftly moving automobile on West Twenty-fifth Street and was struck by the machine. The man died on the way to the hospital and the automobile made off before anyone got its number; thus the possibility of ascertaining the exact circumstances of the accident are destroyed. However, it is almost certain that no strong dancing beam of light was illuminating the surface of the road in front of the car for the man would never have stepped into such an attention compelling and obvious field of danger. I recall a particularly deadly accident that occurred in Cleveland shortly after the first dimming ordinance was put into effect. An automobile came on to Lake Avenue from one of the private drives and was struck by a swiftly moving machine running down the avenue. Four people, as I remember, were killed in the first machine. This accident never would have happened had either one of the machines been projecting a strong beam of light so as to strongly illuminate a strip of the road surface a sufficient distance ahead of the car. I would weary you if I recited the list of preventable night accidents, the accounts of which I have seen published in the Cleveland newspapers. It is a large one and covers only a very small section of the country; yet this list by no means includes all or even a major portion of the accidents that happen in this section of the country. I know from experience that but a small percentage of accidents which occur go on record.

The ever present sections of torn up streets, and numerous spots on the road in need of repairs, and countless other contingencies that arise in the course of automobile driving require adequate lighting to assist in avoiding accidents which may injure people or at least damage the machine. Every one recognizes the advantages and increased pleasure in night driving which accompany an adequate road illumination in front of the car, and until the country-wide agitation against glaring headlights imposed its check the tendency was toward increasingly powerful headlights. As a result of the above-mentioned agitation the trend in automobile lighting has been toward insufficient and inadequate lighting with its attendant accidents and dissatisfaction.

The time is now ripe for a complete study of the whole lighting problem to ascertain what the various requirements are, how they can be met and how the conflicting demands can best be reconciled. In the following pages I briefly present such a study.

In order that this work may be better understood it may be well to give a brief résumé of the basic principles of good lighting.

In studying the principles of good lighting it is necessary to consider phenomena relating to three things—first, the light source; second, the objects to be illuminated; third, the eye.

First, considering the light source. The three most important qualities of a light source are intensity, color of light and distribution. Distribution involves both intensity and direction. Light sources are both primary and secondary. The former emit light, the latter reflect it. The sun and the moon are examples of such sources. An incandescent lamp filament and its reflector is another pair of examples.

Intensity of Source

The intensity of a light source is a measure of its strength, of its ability to produce illumination at a distance. Intensity is either a statement of the strength of the light in a certain specified direction or the average of the intensity in a number of different directions. When this is the average of a large number of uniformly spaced directions covering the whole angular space about the source the result is a measure of the total quantity of light emitted. The unit of intensity is the candlepower. The unit of quantity or, more properly, flux, is the mean spherical candle. Another more recent unit is the lumen, one mean spherical candle = 4π lumens, about 12.5 lumens.

Intensity of Illumination

It is necessary to distinguish between the intensity of a source and the intensity of the illumination produced by a source. The intensity of a source does not vary as we move

---

*Paper read at meeting of Cleveland Section S. A. E., Feb. 18, 1916.

it to different distances, but the illumination produced by a given source diminishes as we measure it farther and farther from the source (if the source is small compared to the distance involved). The intensity of illumination from most sources diminishes as the square of the distance from the source. If the source of illumination is an infinite plane the illumination does not diminish at all at increasing distances from the plane. The nearest practical approach to this in our experience is sky light. The illumination from the sky is the same at the surface of the earth as it is several hundred feet above it. (I shall make use of this point later when I speak of the brightly illuminated surface of the road as a secondary source of light.)

The unit of illumination is the foot-candle; it is the illumination falling on a surface placed perpendicular to the ray at a distance of 1 ft. from a source of one candle. The same surface moved to a distance of 2 ft. would receive an illumination of one-fourth foot-candle.

Another unit of illumination is the lux or meter candle, about 10.7 lux = one foot-candle. Using light flux instead of candlepower the illumination on a surface is equal to lumens falling on the surface divided by area in square feet; this gives the result in foot-candles. If the area is expressed in square meters the result is obtained in lux.

Brightness

The brightness of a surface is not determined solely by the intensity of illumination falling on it, but is also dependent upon the reflecting power of the surface. There are two kinds of reflection, specular, as in the case of a highly polished mirror, and diffuse, as is exemplified in a piece of white blotting paper. The brightness of a diffuse reflecting surface is proportional to the product of the intensity of illumination falling on it and the reflecting coefficient of the surface. The reflecting coefficient of our best white surfaces seldom exceeds 80 per cent, while that of our common black surfaces is seldom less than 5 per cent; most surfaces fall between these limits.

Brightness is measured in candles per square inch. It is also measured in Lamberts, when one square centimeter reflects diffusely one lumen of light its brightness is one Lambert. Candles per square inch multiplied by 0.4868 equals Lamberts.

Color

The next important quality in a light source is color. In some branches of illuminating engineering this has to be considered carefully. In automobile lighting there are so many other important points to consider that the matter of color can be dismissed for the present.

Distribution

If one wished to define illuminating engineering in very few words he would not be far wrong if he called it the scientific distribution of light. The distribution of light intensity in different directions from a light source is a matter of extreme importance. The light from an ordinary headlight bulb is fairly uniform in intensity in different directions where not obstructed by the base. When this bulb is placed in a parabolic reflector the distribution of intensity from the complete unit is profoundly modified. The distribution characteristics of a lamp determine how these lamps should be placed to produce a given lighting result.

Another term used in lighting which really comes under the heading of distribution is diffusion. Diffusion is used with a number of special meanings. "Diffused illumination" is often used to describe an illumination which comes from many different directions as from many small separated sources or from one large, very extended source. Sky light out of doors is perhaps the best example of diffused illumination, and sun light an example of directed or non-diffused illumination. A test of diffusion is the sharpness of shadows cast. Widely scattered light from a comparatively small source is often spoken of as diffused light. This is somewhat confusing. The shadow test will distinguish the two cases.

The second important thing to consider in good lighting, namely, the surfaces illuminated, may for the present be passed with the statement that they are made visible by the light reflected from them or from other surfaces around their borders. They reflect both specularly and diffusely, more often diffusely, and their reflecting coefficients will lie within the range of 5 to 80 per cent.

Characteristics of the Eye

Finally we come to the third and perhaps the most important thing to consider, the eye. The eye is the final judge of illumination. Lighting must be adapted to the peculiarities of the eye. Everyone has eyes, but most people are in the dark regarding some of their important characteristics.

One of the most striking characteristics of the eye is the large range of illumination over which it will operate. The brightest sunlight gives an illumination intensity of about 12,000 ft. candles and bright moonlight about .03 ft. candles, a range of intensity of 400,000 to 1. If one passes suddenly from bright sunlight to surroundings illuminated to the intensity of bright moonlight the latter would appear perfectly dark and it would take considerable time before vision would be good. A very much smaller change than this has a very pronounced effect of the same sort. When the eye attempts to see in a reduced illumination its sensitiveness to light increases. This change in sensitiveness is not wholly due to a change in the opening of the iris of the eye as is sometimes popularly stated. The difference in the opening of the iris can nowhere nearly account for the magnitude of the change in sensitivity which is observed. Other very important changes which require considerable time take place within the eye. This increase in sensitivity when surrounded by very low illumination is often called dark adaptation.

When the eye is suddenly changed to greatly increased illumination it is pained, but in a short time adjusts itself comfortably to its new surroundings. The eye adapts itself to brighter surroundings more rapidly than to darker ones. That is, its increase in sensitivity with a given change in surroundings is slower than its decrease with the same amount of change in the opposite direction.

When two surfaces within the field of view are illuminated to very different intensities the eye cannot see them both clearly at the same time nor can it view the brighter and then immediately see well on the darker. For accurate vision on the darker surface the eye requires time for adaptation. If there is any considerable area of the brighter surface in the field of view the eye cannot adapt itself to see well in an area considerably darker. This peculiarity of the eye calls for uniformity of illumination of the field of view.

Contrast

A bright area adjacent to a dark area where the ratio of brightness of the bright to the dark area is very large, causes discomfort and glare, a condition with which we are all familiar. Precise quantitative figures on just what conditions of contrast cause glare and how much glare is caused under any given conditions are not available, but the general factors which go to make up glare are known.

Contrast, or the difference in brightness of an object and its immediate surroundings is a very important factor, but it alone does not determine glare. We have in addition to consider both the absolute brightness of the bright object and also the areas or visual angle involved. For instance, the contrast between some of the fixed stars, which have a far greater intrinsic brilliancy than the sun, and the dark space around the star represents about as large a contrast as we can obtain, but this combination does not cause glare. The reason is found in the very small visual angle subtended by the star. For the same reason the bare filaments in headlight bulbs of the sizes in common use to-day do not cause glare to an oncoming driver, although they are very much more brilliant than the surface of the reflector viewed from the direction of maximum intensity of beam. But we all know that when the eye is in the projected beam a moderate distance from the car glare is produced when the surroundings are dark. In this case the brightness of the reflecting surface is very much less than the filament, but the visual angle subtended is so very much greater, 1800 to 1, that the actual amount of light entering the eye from the reflector is much larger than that coming directly from the filament. Again, a very dimly lighted surface contiguous to an area absolutely black would give a large contrast ratio, but this combination would not cause glare. This would indicate that absolute brightness is also a factor.

We see from the above that we can do three things to lessen glare:

First—Reduce the contrast between the bright object and its darker surroundings either by dimming the bright object or by brightening the dark surroundings.

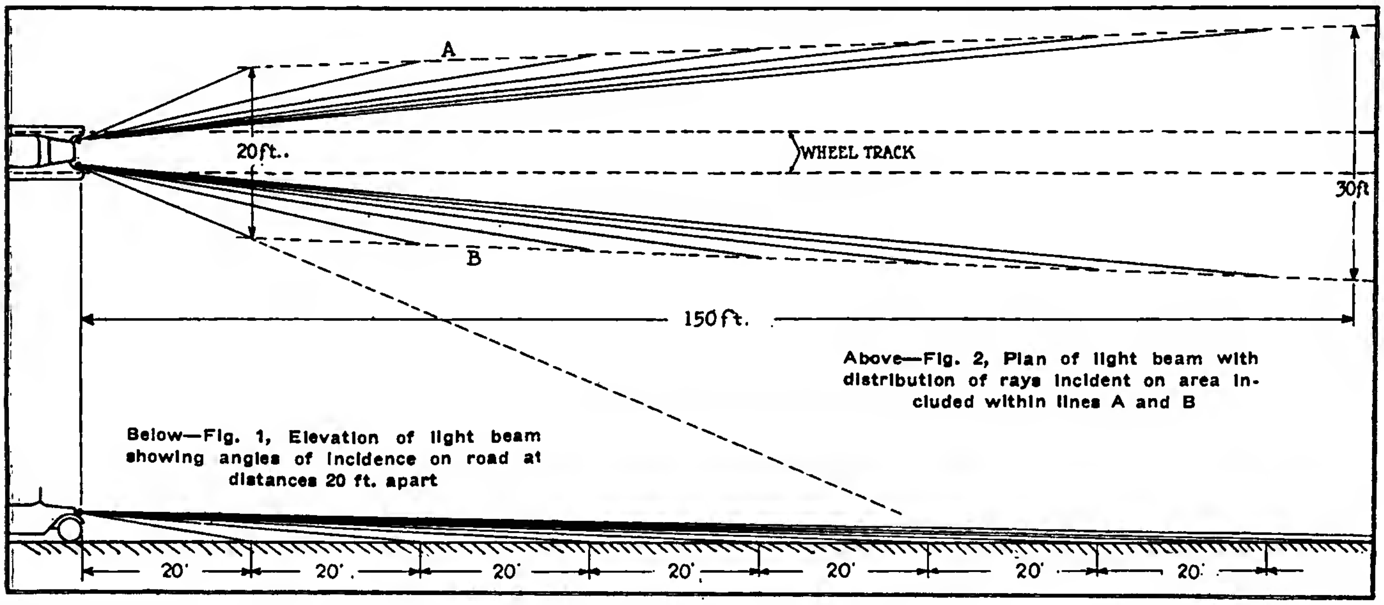
Second—Reduce the angle which the bright object subtends at the eye either by making the object smaller or by getting farther away from it.

Third—By reducing the brightness of the bright object still holding the contrast the same by correspondingly dimming the surroundings.

There is another peculiar characteristic of the eye that has an important bearing on automobile lighting. This is the change in the acuity of vision with the size of the field illuminated. This effect was first announced by Dr. P. W. Cobb of the National Electric Lamp Association and was further studied by Dr. P. G. Nutting of the Eastman Kodak Co. These men have shown by experiment that an illuminated object can be seen much more distinctly when surrounded by a large illuminated area of the same order of brightness, than when surrounded by a dark or dimly-lighted area. Or, putting it in another way, the illuminated object can be seen equally well in a much weaker illumination if the weaker illumination covers a wide area surrounding the object than when the illumination is confined to the immediate neighborhood of the object. This effect is of large magnitude and its importance should not be overlooked in studying the automobile lighting problem. It indicates that for the best results in seeing objects on the road, a large area of the road surface should be uniformly illuminated. The illumination should not be confined merely to a width of the road actually traversed by the car but should extended a considerable distance to both sides of this strip.

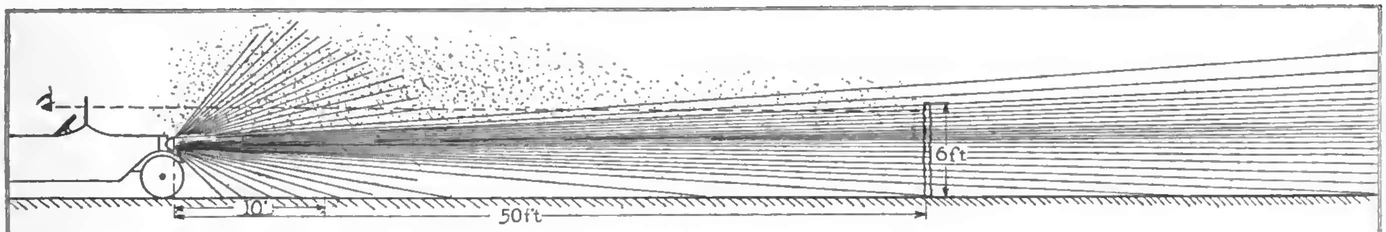
Another advantage of an extended illuminated area is that approaching drivers and pedestrians are much less sensitive to glaring lights when this large illuminated area is in front of them. The brighter the surroundings the more intense must a light be to cause glare. In full sunlight we would barely notice a powerful headlight shining directly in our eyes from a moderate distance.

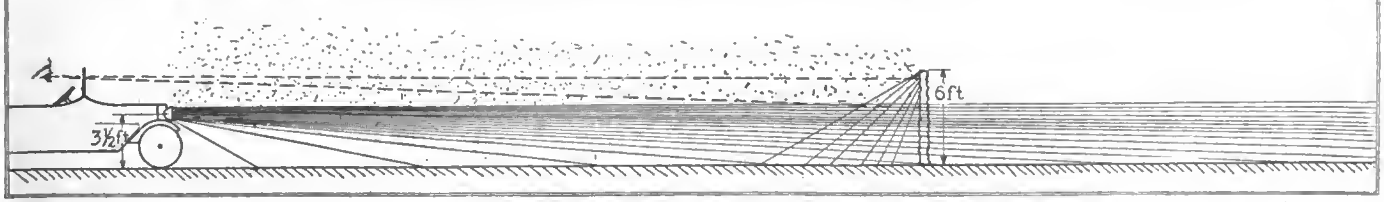
Having now reviewed the important fundamental principles of good lighting we are ready to consider more specifically the requirements of the automobile. We have to consider here first, the requirements of the driver; second, the drivers



Above—Fig. 2, Plan of light beam with distribution of rays incident on area included within lines A and B

Below—Fig. 1, Elevation of light beam showing angles of incidence on road at distances 20 ft. apart





Above—Fig. 3, Form of beam which glares. Below—Fig. 4, Illumination that is non-glaring and occupants of other vehicles, and third, the pedestrians on the road, also some special conditions which the machine is likely to encounter. The merits of any particular installation of automobile lighting cannot be judged solely by the ease and comfort with which a driver can operate the car under some particular conditions. The demands of safety under a wide variety of conditions must also be considered. The tendency in passing judgment is to overlook some important points, just as in figuring costs the tendency is to leave out some important items.

First, considering the requirements of the driver, he would be satisfied if he could have daylight or something closely approaching it. Daylight is characterized by a high intensity of illumination of great uniformity and extent. The intensity of average daylight illumination is a thousand times greater than our best artificial street lighting. Such light as this for the automobile is obviously out of the question. It is equally impractical to suggest that all roads traversed by automobiles be provided with street lighting on the same scale as our best lighted city thoroughfares. Even if this were practical it would fail to meet some of the important safety requirements.

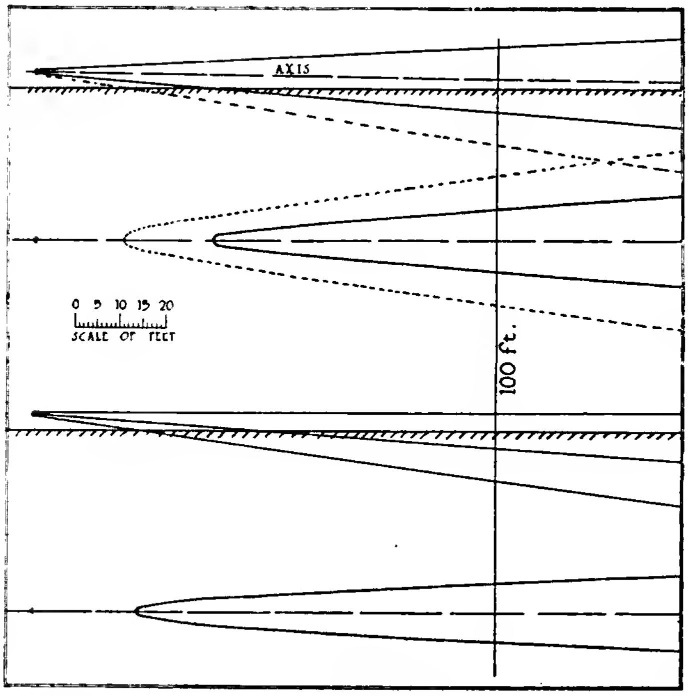
The driver will find it easy to operate the car if the road ahead of him is covered for a considerable distance, say 200 ft., with a strong uniform illumination which enables him clearly to see ruts and stones or any obstacle in his path. This illuminated area should be wide enough to show turns and enable the driver to select the smoothest part of the road. Extra width is also valuable in disclosing landmarks and dangers such as animals wandering along the side of the road which might dash suddenly in front of the car at such close range as to make collision certain. A liberal width of illuminated surface is also advantageous for increasing the efficiency of vision as was mentioned under the characteristics of the eye. Though desirable, we do not have to maintain uniformity over the full width of the illuminated area. The outlying portions will still be very beneficial even if considerably weaker in intensity, but large increase in the illumination in spots and patches over what is necessary to see should be carefully avoided because such spots not only waste light that could be better used elsewhere, but they also cut down the visual efficiency of the eye on the remainder of the illuminated area.

For safety on crossings and rounding curves there is needed a strip of illumination on the surface of the road extending at least 200 ft. in front of the car and with a diminishing intensity extending beyond to 400 or 500 ft. For this purpose the width is not so important but the brightness must be great enough to be easily seen in the presence of ordinary street lighting. This is a particularly important safety measure. Two cars approaching each other at a crossing can see each other's beam of light on the road ahead when the cars themselves are obscured from each other and ample precautions can be taken to avoid a collision. To be plainly visible under various conditions a strength of beam sufficient to give a horizontal illumination of 0.025-ft. candles at 200 ft. should be used. Such a beam will also attract the attention of and warn a pedestrian crossing the street that a car is approaching even when he is not looking toward the car. It will also make the pedestrian visible to the driver if he gets in the path of the car, thus giving a double measure of safety. An illumination on the road such as is described above can in itself harm no user of the road, but will benefit all parties concerned.

The question now arises, How can we secure such an illumination? We cannot space a number of lights along the street as is done in street lighting, for our illuminated area must travel with the car. We cannot even mount units on the car at heights which are customary in good street lighting for we would soon bump into overhead work. We must then produce this illumination from units mounted at some convenient height on the car. (This question of effect of height will be discussed later.) In order that lamps mounted on the car shall produce the illumination mentioned above it is necessary that they direct toward each portion of the surface to be illuminated an appropriate strength of beam, not too strong toward any part or light will be wasted, nor too weak or it will be ineffective. The above specifications call for a very closely controlled distribution of light. In order to show what the general distribution characteristics of the lamps should be in order to furnish the above mentioned illumination, I have drawn Figs. 1 and 2. In Fig. 1 a series of points are laid off every 20 ft. on a line representing the road level and each one of these points is joined to the center of the lamp mounted 3½ ft. high. For uniform illumination it is necessary that equal areas receive an equal amount of light flux. Light flux divided by the solid angle through which it is delivered gives intensity or candlepower. Equal areas more distant from the lamp subtend smaller solid angles, hence the light directed toward the more distant areas must be more concentrated or intense. It will be noticed that the top part of the beam illuminates the more distant sections of the road and therefore must be more intense. The intensity must diminish gradually as we pass to the bottom of the beam.

Referring to Fig. 2, which is a plan view diagram, a strip of road included between the dotted lines A and B is assumed illuminated. Lines are drawn to the lamps from points on the edge of the illuminated area spaced every 20 ft., as in Fig. 1. It will be seen that the lines from the most distant pair of points include the smallest angle, and from the nearest pair the greatest angle. The angle between any pair of these lines represents the sidewise spread which the light directed to the points in question must have to give the desired width of beam. To illuminate the strip shown in Fig. 2, the light must have the least sidewise spread at the top of the beam and the greatest at the bottom and increase gradually from the top to the bottom.

It will be interesting to compute how intense an average illumination can be obtained on the above described area with a size of light source within the limits now in use, when the light is uniformly distributed. The total lumens of light



Above—Figs. 5 and 6, Elevation and plan of beam set to strike road at 250 ft. from lamp

Below—Figs. 7 and 8, Diagrams of beam for same lamp tilted 4 degrees downward available divided by the area in square feet uniformly illuminated gives the intensity of the illumination in foot candles. Taking the strip 20 ft. wide at the car and 34 ft. wide at 200 ft. in front gives an area of 5400 sq. ft. Assuming two light sources each projecting 20 mean spherical candles, gives 4 x 40 = 503 lumens, which divided by 5400 = 0.093 foot candles, or 1 lux strength of horizontal illumination. Bright moonlight is about 0.25 lux, so the intensity of the illumination above calculated is four times that of bright moonlight.

A 1000-candlepower street lamp mounted 20 ft. high gives a horizontal illumination of 0.079 foot candles, or about 15 per cent less than in above calculation at a distance of 60 ft. This intensity of light will show most road surfaces very clearly and when projected from the lamps on a car will show obstructions on the road with great clearness because the vertical illumination which is effective in illuminating projections is many fold stronger than the horizontal illumination.

To allow for the effect of pitching of the car and to make objects visible beyond 200 ft. some light should be projected from the lamps above the beam striking at 200 ft., although it will not be necessary to preserve the uniformity of the road illumination from here on ahead. If less light is available than that assumed above it will be better to keep a narrow strip down the center of the road up to the intensity calculated to serve as a warning at crossings and let the weakening of the illumination be borne by the sides of the strip. However, it would be better to use more light rather than less.

Avoiding Glare

There is a growing tendency to regulate glare by specifying that no strong beams of light shall be projected above a level of 42 in. more than 75 ft. in front of a car, the measurements to be made on a level road. This is decidedly a step in the right direction in regulating lights. The eyes of substantially every user of the road are well above this level, and it is only when a car pitches on a rough road, thus tilting the beam upward, and when rounding the top of a hill that the beam will shine into the eyes of persons facing the car, and the duration of these flashes will be very short and they will very seldom occur except while the approaching car is at a considerable distance, leaving ample time after the flash to pick out a safe course on the road. No possible adjustment of the lighting can avoid the occasional flash just mentioned and preserve lighting that is either safe or satisfying. At the tops of hills the glare could be eliminated by the installation of very brilliant local street lighting. The flashes from pitching could be remedied by smoothing the street surface.

Frosted Glass Wasteful

It has been suggested that glare be reduced by covering the front of the lamp with diffusing glasses which scatter the light. This is very wasteful and unsatisfactory; it gives a distribution of light which is most intense directly in front of the car and which diminishes rapidly as the distance increases, and is ineffective at a distance. In addition this strong scattered light forms an illuminated curtain which blinds the driver in fogs and in snowstorms. This blinding effect is illustrated in Fig. 3. The dotted line represents the line of sight to a 6-ft. high object in front of the car. The long lines represent a strong beam of 8 deg. spread with the center set to strike the road at 200 ft. The short lines from the lamp represent strong scattered light such as would come from a diffusing glass front or other light scattering means. The particles of fog or snow surrounding the line of sight to an object reflect light back into the eye and prevent seeing the object. Fig. 4 represents how this danger is avoided with a distribution of light in which no strong light from the lamp rises above the top of the lamps set at 3½ ft. The portion of the object above the beam of light is illuminated by the diffused light from the surface of the road. This diminishes very slowly in intensity as we go upward because of the large size of the source.

Illumination by Ordinary Parabolic Reflector

Having described what is desired for good automobile lighting, it will be interesting to examine the results obtained by the ordinary parabolic reflector that has been so much used and point out its merits and its defects.

The ordinary parabolic reflector (See Fig. 13) with the light source centered on the focus gives a concentrated beam of light which is most intense along the axis of the reflector, and which diminishes in intensity as we move away from the axis in any direction. At the edge of the beam the intensity is only a small fraction of the intensity in the center. The distribution is symmetrical about the axis. The angle of spread of the beam is approximately equal to the largest angle which the light source subtends from any point on the reflector.

The spread of a beam varies with the size of light source used. A mathematical point would give no spread, that is, it would give parallel rays. But it must not be overlooked that a mathematical point would also give no light.

Focus Affects Beam

Drawing the light source either forward or back of the focus increases the spread of the beam and also greatly reduces the intensity of the center of the beam. If the light source is moved sidewise from the focus, the center of maximum intensity of the beam moves in the opposite direction.

Fig. 5 represents the beam from a parabolic reflector having an 8-deg. spread mounted 3½ ft. high and set with the axis of the beam striking the ground at 250 ft. The full lines in Fig. 6 represent the intersection of this conical beam with the ground, the area inside the full lines is illuminated by the beam. The beam strikes the ground 38 ft. in front of the lamp and does not have a sufficient width to give good results until a distance about 90 ft. in front of the car is reached; beyond this distance the illumination is sufficient. The beam is high enough to glare beyond 30 ft., so this is not "no-glare" lighting.

Light Lost by Tilting Lamp

Fig. 7 represents this same lamp tipped down 4 deg. below the horizontal so that the top of the beam is horizontal. The center of the beam then strikes the ground 50 ft. in front of the lamp, producing a very bright elliptical-shaped spot of small width. The edge of the beam strikes the ground about 22 ft. in front of the lamp. Fig. 8 is a plan view of the intersection of the beam with the road. The intensity of the road illumination diminishes rapidly beyond the 50-ft. point, and its effectiveness dies off even more rapidly because of the presence of the very bright area around the 50-ft. point. This lighting has just one merit—it does not glare. Its defects are: First, too dim at a distance; second, too narrow everywhere; third, too great inequality in intensity.

Spreading the beam to reduce the intensity of the spot requires that the lamp be tipped more to avoid glare, thus bringing the axis nearer the car and still further lessening the effective distance of the illumination already too short. Tipping the ordinary parabolic headlight as a solution of the automobile lighting problem can be dismissed as absolutely unsatisfactory.

To show definitely the distribution of illumination produced on the road by a representative parabolic reflector and the change produced in this illumination by tilting, I have prepared some carefully computed illumination curves based upon the distribution curve of a standard make of 9-in. parabolic reflector of 1¼-in. focal length with a 20-candlepower 6-volt bulb.

These (on the page opposite) represent the distribution of intensity of illumination on the road. The full line curve with the center of the beam pointed to strike the ground at 200 ft., the dashed curve for the beam tilted down 4 deg. from the horizontal or with the center of beam striking at 50 ft.

Curves Show Illumination

Two curves are drawn for each setting of the lamp, one representing the illumination as measured normal to the beam, the upper curve, the other the horizontal illumination to which the brightness of the road surface is proportional. The normal illumination at any point is always greater than the horizontal, when the beam strikes the ground obliquely as is the case in automobile lighting.

Considering first the horizontal illumination with the 200-ft. setting, there is a very dimly lighted space between the 20-ft. and 40-ft. point. Beyond 40 the illumination is good, reaches a maximum of 0.17 foot candles at 80 ft. and falls gradually to 0.023 at 200 ft., which is equivalent to good moonlight; beyond 200 ft. the illumination gradually dies away. It is to be noted that the normal illumination which comes into play in illuminating a projection or obstacle on the road is still high at 200 ft. and for a considerable distance beyond.

Consider now the horizontal illumination curve of this lamp tilted 4 deg., which is necessary to bring it to a "no-glare" position. There is a dim space at 20 ft., but from there on the illumination rises, rapidly reaching a maximum at 40 ft., which is eleven times the maximum of the 200-ft. setting. It falls rapidly from this point, becoming ineffective beyond 80 ft. The normal illumination also falls off rapidly and is ineffective beyond 115 ft. This illumination is very bad because of its great and abrupt variation. The area covered with sufficient intensity is small and the visual efficiency of the eye is much reduced both on account of the small area and because of the enormous and abrupt variations in intensity.

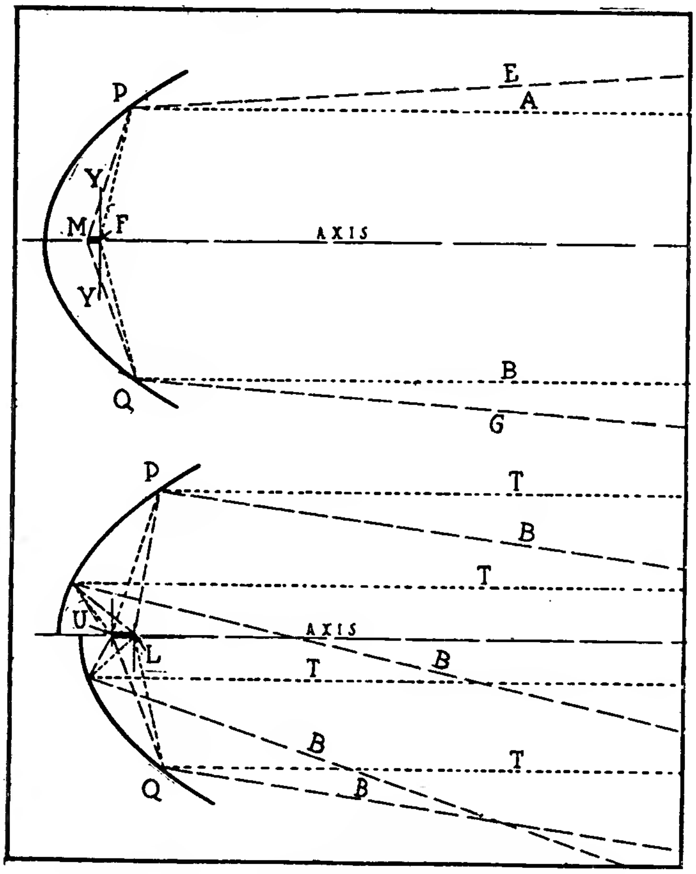
The right hand curves of illumination for the two settings just mentioned, are taken at various distances across the beam. They form a sort of topographical map of the illuminated surface of the road for the two cases.

These curves show that the same enormous increase in variation that existed lengthwise of the beam in the 4-deg. tilt curve also exists across the beam, and the effective width is thereby reduced.

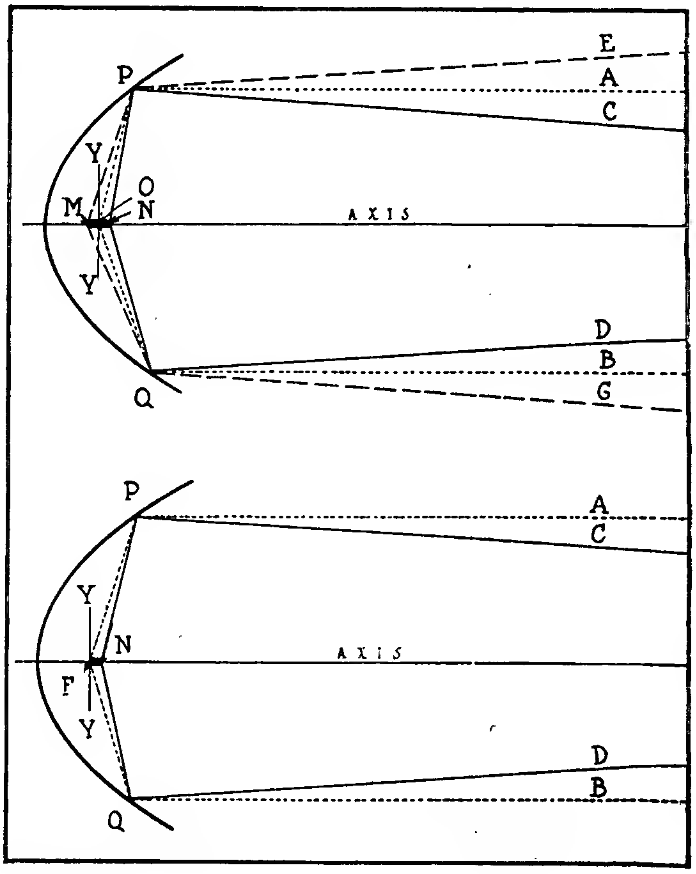
Improved Modifications of Parabolic Reflector

I will now describe how the plain parabolic reflector may be modified to give a more suitable distribution that may at the same time be so directed as to be free from glare. First let us examine more minutely the action of a parabolic reflector. Considering Fig. 11, this represents a section through the axis of a parabolic reflector with a cylindrical filament *MN* centered on the focus *O*. Rays from the focus *O* striking the reflector surface are reflected parallel to the axis, as represented by *OPA* and *OQB*. Rays coming from any other position are reflected at an angle to the parallel ray, which is equal to the angle between the incident ray and the incident ray from the focus to the same point. This follows simply from the law of reflection that the angle of reflection from a mirror surface is equal to the angle of incidence on the mirror.

Thus in the figure the angle *EPA* equals angle *MPO*, also *CPA* = *NPO*, *GQB* = *MQO*, and *DQB* = *NQO*. Similar relations hold for light from any point in the source striking any point on the reflector. It is thus seen that the beam from a reflector is made up of an infinite number of these diverging cones of light coming from all points on the reflector. It will be noticed that light rays coming from points on the filament that are in front of the focus converge toward the axis, and from points behind the focus diverge from the axis. The beam of light from this reflector thrown on a screen will have a distribution of intensity represented in Fig. 13, strongest in the center and diminishing toward the



Figs. 9 and 10, showing effect of dividing reflector

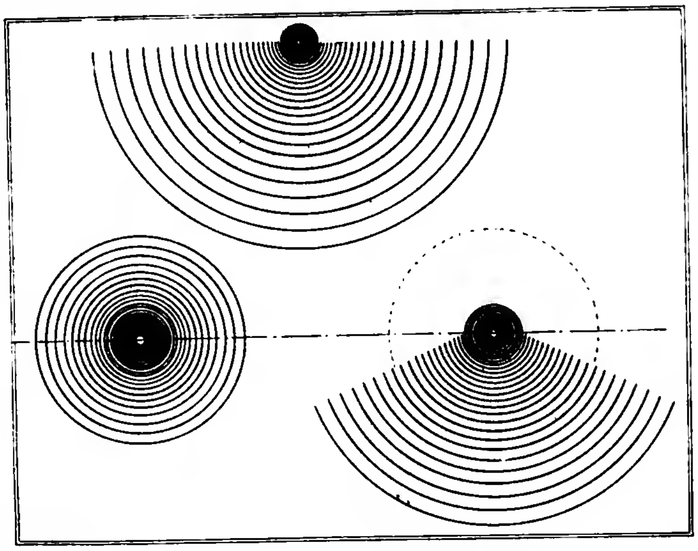


Figs. 11 and 12—Effect of position of filament relative to focal point edge. If the reflector is viewed from a point in this beam not too close to the edge its whole surface will appear brilliant because each point of the surface is sending out a little cone of light which strikes the eye.

If now the half of the filament in front of the focus is removed we have the condition shown in Fig. 9, where all of the little cones of light diverge from the axis, the innermost edges of the cones being parallel to the axis. This beam thrown on the screen would be very similar in light distribution to the beam thrown by the last described adjustment; it has the same spread, that is, covers the same area, but since half the light source has been removed, it is only of one-half the intensity. If we put our eye in this beam a little to one side of the center and view the reflector only one-half of it is bright, and that is the half on the same side of the axis that the eye is placed. The little cones of light all spreading away from the axis do not cross it and strike the eye.

If instead of the front half of the filament we remove the half back of the focus, Fig. 12, all of the little cones of light will converge toward the axis and cross it and diverge from it after crossing. When thrown onto a screen this will give a spot very similar to the one just described, except that it is smaller by the diameter of the reflector (which fact is of small importance in automobile work). The important difference is that when the reflector is viewed as before from a point in the beam a little to one side of the axis, the opposite half of the reflector is bright, and the near half dull. Thus in Fig. 19 the reflector viewed from the point *D* would appear bright on the lower half.

With the filament extending equally on both sides of the focus the cone of light from each point on the reflector spreads equally in all directions from the axis, and if we were to remove any portion of the reflector surface we would simple cut down the intensity of the beam as a whole, but would not change its shape. But with all of the filament to one side or the other of the focus the little cones do not all superpose, but each occupies a definite position in the beam. We can then change the shape of the beam by removing certain of these constituent cones. If, for instance, we take half of the reflector away we have a beam which gives a spot like Fig. 15 without the little hump at the top. This same shape is given with one-half of the reflector with either of the filament adjustments shown in Fig. 9 or Fig. 12. This type of beam has its maximum intensity on the axis and diminishes as we go from the axis outward radially in any direction below the horizontal plane through the axis. Above the plane through the axis the light is nearly all suppressed, since it came from that portion of the reflector that has been removed. It is possible to make the hump that extends upward in Fig. 15 larger by moving the filament toward the focus so that it overlaps the focus more.

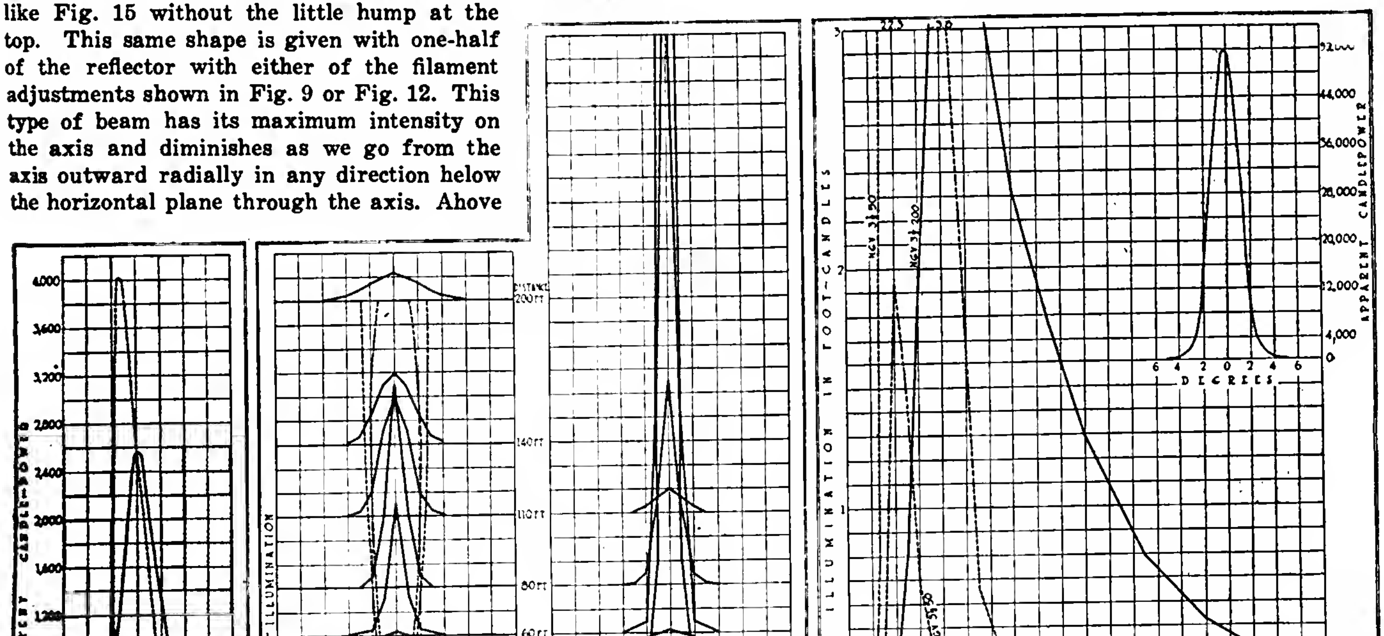


Figs.—Left 13—Right 14—Upper 15

Gives Ideal Illumination

This type of beam gives a closer approach to the ideal distribution desired than any other available. When pointed so that the axis strikes the ground at about 200 ft. and with a center hump large enough to reach up to a 3½-ft. level. The beam gives a broad strip of fairly uniform illumination extending clear back to where direct light from the bulb filament is effective. (This is assuming that the lamp and the filament used are designed to give the proper spread for the mounting height used.) There is no beam light in the glare region above 3½ ft.

(To be concluded)



Illumination curves for horizontal and tilted lamps mentioned on page 414

Anticipating Complaints in Service*

A Scientific Application of Service Experiences to the Prompt Betterment of Production

By F. A. Cornell

INDIANAPOLIS, IND., Feb. 26—How the engineering department of a motor car factory can utilize the complaints which come into the service department to the best advantage in designing new models or making minor changes was explained to the Indiana Section of the Society of Automobile Engineers at the Claypool Hotel last night. This explanation was embodied in a paper presented by F. A. Cornell of the Perfection Spring Service Co., who for a number of years had charge of the service department of the Willys-Overland factory, Toledo, Ohio. Although the title of the paper, "Anticipating Complaints", is the correct one, there undoubtedly would have been a larger number of the engineers in attendance had the author adopted some such title as "How Factory Engineers Can Capitalize on Kicks."

As it was, the service departments of the Indiana car and accessory factories were much better represented than were the engineering departments, a regretable feature inasmuch as both the paper and the lively discussions thereon were full of suggestions and inspirations for the prompt betterment of factory production.

During Mr. Cornell's experience in service and sales work he has developed a plan by which complaints on account of wear and breakage and other difficulties can be charted and segregated by the service department, to convey to the engineering and sales departments exact and immediate information as to the cause and seriousness of any wrong design or materials and show what changes in design, inspection, specifications or factory processes may be needed to correct the fault and thus make sure that the same error is not carried through in later production. The paper (slightly abridged) follows:

The first and easiest step is to build up a complaint system. Through some convenient but invariable path all criticisms should be cleared, analyzed, tabulated, and reported to all interested departments. Grouping of such complaints under several general divisions of car lay-out is too generally used to require further explanation.

But the immediate and vigorous study of these reports is more often from commercial than technical sources. Possibly it seems beyond the reasonable to expect a capable engineer to give ready heed to comments that are so often unfair, and so very seldom thorough. But the fact remains that a Complaint System usually requires the vigorous insistence of a commercial executive before real action is taken.

However, the Complaint System should be retained and supported by another method that introduces mathematical analysis. Possibly all the necessities for replacements might be divided between two general causes: (1) The wear, or (2) the breakage of individual parts. These may be subdivided as falling in one or another of four groups, by the cause of the damage. In further detail these four groups might be adapted to more exact usage along the lines of the following:

Not a single operating engineer might agree exactly with the classifications suggested. They are not offered as a working scheme that should be put into use at once in this form. It is hoped, however, that many such distributions of service damage are now employed. To such executives, this paper will offer a broad opportunity for constructive discussion. To all builders in the world of mechanics this message cannot go far astray: "Get scientifically close to the proofs of your pudding."

Causes for Replacement

Worn (W) or Broken (B).

1. *Inherent Defects.*
    - (*a*) Flaw in Texture.
    - (*b*) Error in Alloy.
    - (*c*) Early Crystallization.
    - (*d*) Wrong Material Specified.
2. *Manufacturing Irregularities.*
    - (*a*) Wrong Material Used.
    - (*b*) Incorrect Treatment.
    - (*c*) Error in Machining, etc.
    - (*d*) Improperly Assembled.
    - (*e*) Lack of Thorough Inspection.
3. *Damaged in Normal Service.*
    - (*a*) Failure of Associated Mechanism.
    - (*b*) Adjusting Assembly not Reasonably Permanent.
    - (*c*) Insufficient Provision for Lubrication.
4. *Damaged in Abnormal Service.*
    - (*a*) Lack of Reasonable Lubrication.
    - (*b*) Lack of Reasonable Adjustment.
    - (*c*) Driving Accident.
    - (*d*) Unusual Driving Damage.

It is true that a tabulation of *all known* replacements offers only an indication of efficiency. Mathematical accuracy could be had only by analysis of *all* replacements. But the repeated contributions of "the kicker" offer opportunities that should be improved as scientifically by the technical departments as they are concluded diplomatically by the selling staff.

The primary point of this paper is to indicate that more attention has been given toward seeing "the kicker" satisfied than in being scientifically certain that each possible cause for complaint is quickly corrected. Let us illustrate how such purposes may be accomplished by sketching the development of a quantity producer's efforts. His scientific scheme was disguised as a game. Even the day laborers became interested in the fluctuation of a "Parts Batting Average."

Developing the System

Each piece returned for replacement or repair was carefully inspected. The cause leading to its condition was reported by the code of our brief (such as W2c, advising the recording and corresponding clerks that the part was worn through an error in machining and therefore in line for free replacement).

It should be noted that those causes that were up to the car owner are listed last as Group 4. It was the plan to exhaust the possible application of any of the rulings under 1, 2 or 3 before refusing credit on the grounds that the factory was not to blame for the damage. It is imperative that fairness be maintained, but that in any case of doubt the customer should be given the benefit and that the manufacturer should carry such doubts as reason for careful watch and study.

This is as far as the ordinary system goes. Now for the "Batting Average." On a proper form, such replacements were tabulated by part numbers. The sub-totals may be taken to show repeti-

---

*A paper presented at Indiana Section S. A. E., Feb. 25, 1916.

tions from individual causes. But, better than all, the entire replacements of a part were computed against the total production of that model to the first of a prior month. Should 1200 cars have been delivered up to May 1, and if 12 transmission countershafts, No. 4901, had been replaced up to June 1 of the year, the efficiency of that piece was 99 per cent, and this was shown in the last column of the form.

The Score Board

Such percentage figures make fine information, but more was wanted than to know. A blackboard was placed where the men congregated and the parts leading in non-efficiency were listed thereon in the order of their disfavor. Associated departments soon vied with each other in efforts to excuse the humiliation of leading the list. The jeering remark, "You fellows have a lot of heavy hitters this week," did more to clean out the weaklings than any one other scheme.

Group 1 covered causes within the selection of materials, usually applying to outside suppliers. Group 2 covered errors properly chargeable to a factory department. Group 3 to the engineers and Group 4 to the user. The service department, with sales co-operation, constantly strived to reduce the replacements due to causes within Group 4 by vigorous educational efforts.

But even the "batting averages" and the "score boards" seemed to have limitations. Final and most intensive application of all service experiences was not obtained until the breakage was plotted. This was the effective step *in anticipating complaints*, since the relative efficiency of associated parts was so graphically shown.

The Service Curve

A great many successful enterprises have been developed upon the principle, "the customer is right." While some merchants seem to disagree with so broad a policy there will be a few so stubborn as to deny that many purchasers having a just complaint do not present it to the vendor. Most men want to live agreeably.

It is, therefore, easily possible for some serious faults to go along unchecked unless all the known sources of complaint are tabulated and analyzed. The best trade connections would far rather send in orders than complaints. When they do find fault it is often from just causes that might have been quickly corrected by scientifically cultivating "the kicker."

A careful plotting of a service curve, a broad belief in the fairness of humankind, and a vigorous determination to be sure that we are not at fault before blaming the buyer—all these will go far toward the perfection of car design. The purpose of this paper is to suggest the application of simple and convenient figures as a stimulant to correction before a wide harm is done.

Discussion of Cornell's Paper

Discussion of the paper was opened by E. T. Klee, service manager of the Stutz company who agreed that a system similar to that outlined by Mr. Cornell would be valuable in assuring co-operation between the service and engineering departments, particularly in large organizations where the two departments did not come in contact frequently.

It was the opinion of E. M. Elliot, general manager, Mais Motor Truck Div., Premier Motor Corp., that the chief problem was to make the management of the concern appreciate the truth of the findings of the service department. It was his belief that the service manager ordinarily was made the "fall guy" to placate the owner who complained of mistakes made in other departments.

George A. Weidely of the Weidely engine company, stated that the problem was to get the data in such shape that the management will pay attention to it. He thought that if it was presented in the way outlined in the paper, that it would get attention, and that such a system would go as far as anything to make the American motor car a better car.

Thinks System Good

R. H. Combs, consulting engineer and general traffic manager Prest-O-Lite company and secretary of the section, gave it as his belief that a system such as that outlined would have the desired effect; that this co-operation between the service department and the other departments of the factory was a matter of evolution and will work itself out as the industry grows. The service department was brought into being to relieve the management and the engineering department from complaints, and these departments did not realize the value of the service department from the engineering standpoint.

Service Manager Drew of the Nordyke & Marmon Co., stated the need of appealing to the head of the organization through the expenses of the service department, that it is easier to reach the management through the pocket-book than any other way. He was in favor of a classified accounting system, so as to show the value of the department as a business, distinct from the new car business. He stated that many factories now lump the appropriations to be spent in service work and the accounting is guesswork without any method of knowing the returns from the service department. The expense feature could be worked out showing the cost of each of the various items.

He suggested that a feature that should be taken care of in such a system outlined by Cornell was the analysis of complaints which did not refer to defective parts. This might include such as the construction of the top, or the windshield, or the body design. He quoted Alvin McCauley in the statement that the advertising department has a very close relation to the service department in that the service department must make the car live up to the claims the advertising department has made for it.

Elaboration Suggested

Mr. Cornell suggested an elaboration of the system or rather an extension of its use by which the sales department could tabulate the complaints by territories and thus develop a system for determining what dealers expect too much service attention, such as getting road men to make minor adjustments which the dealers should take care of themselves. This he believes would be of value to the Sales Manager in determining the character of his distributors and dealers.

Commenting on the relation of the advertising and service departments, Mr. Cornell stated that the ideal arrangement was that in force in the Stearns organization when one man was both the advertising manager and service manager. He warned the service men not to rely too much on the dealers' reports, because these were likely to be biased and frequently not made by men of sufficient technical experience to determine whether or not a complaint was just.

He also suggested that it was possible by the system he outlined to put up a danger flag in case there was something radically wrong with a certain part, and thus correct it in a hurry. The service department should take as much pride in getting a complaint as the salesmen do in getting an order.

Asked by Secretary Combs what was done in case broken parts were not returned, the speaker stated that some concerns had a parts auditing service in which traveling auditors examined and passed on defective parts turned in to the dealer and at the same time assisted them in maintaining their parts stock.

Eliminates Mortality

David Landau, consulting engineer of the Sheldon Axle & Spring Co., said that the service department system eliminates the mortality of parts in the new design, and asked upon what basis the efficiency of parts was calculated. That is, what should be the assumed life of a part, or life of a car. In answering this, Mr. Cornell said that the effort was toward making a replacement of parts as nearly constant as possible, that is, in having one part come in for replacement no oftener than others. It is to be assumed from this that Mr. Cornell had as an ideal car one in which no one part wore out quicker than another, and that when it failed, it failed completely like the classic "One-Hoss Shay."

The FORVM

THE QUESTION OF INFLATION—COULD STANDARDIZE BODY DIMENSIONS—GRANT SIX CONFORMS TO AUTOMOBILE'S SUGGESTED PROPORTIONS

Relation of Load Per Wheel to Tire Inflation

By Charles E. Manierre

SINCE the recent publication in The Automobile of my letter advocating the use of oversize tires, a paper by P. W. Litchfield, in the transactions of the Society of Automobile Engineers of 1915, has been called to my attention. Mr. Litchfield, among other things, speaking of the advantages of the oversize tire says:

> "The average car owner never knows what good tire service is until he equips his car with tires one or two sizes larger than those furnished by the manufacturer. Punctures disappear like magic, premature tire wear and carcass failure become things of the past, and riding similar to that of a Pullman car is afforded."

His paper further emphasizes the saving of expense to owners through the use of such tires, and in passing he calls attention to the diminishing liability to puncture as the size of the tire increases.

Incorporated in his paper is a table somewhat similar to that incorporated in the letter of Mr. Parsons, to which I referred in my recent communication. This table gave the proper tire inflation in pounds for tires from 3 to 6 in. in section diameter, and for each section diameter and inflation pressure the corresponding suitable weight to be carried by each rear tire, the rear tire apparently being chosen as having more strain upon it, due to the driving effort, and therefore the inflation suitable for it would be perhaps a trifle more than sufficient for the front wheel.

The table of Mr. Parsons was arranged on the basis of a load per wheel in even hundredweights of 112 lb., for cord tires of various cross-sections, and consequently as to some of the sizes the pressure figured up to odd pounds, e.g. 32, 44, 56, etc. It chanced, however, that for the 3½-in. tire and the 6-in. tire the inflation in pounds increased in multiples of 5, e.g. 30, 35, 40, etc., as in the table of inflation pressures contained in the paper of Mr. Litchfield.

The earlier paper had to do with cord tires, and a comparison of the two shows roughly that allowance in Mr. Litchfield's table, in the smaller sizes, was from 33 to 50 lb., and in one instance nearly 100 lb., less of indicated carrying capacity per wheel, while in the larger sizes, particularly the 5-in., the carrying capacity was as much as 100 and more pounds greater than that indicated in the earlier table. While again, in the 6-in. size the two tables did not differ more than 20-40 lb.

However, these differences rather emphasize the fact that the independent tables had arrived at conclusions not very dissimilar.

The later table indicated the most satisfactory working load and pressure as follows:

In.	Lb. Pressure	Lb. Load Per Wheel
3½	50	515
4	60	750
4½	65	975
5	70	1225
5½	75	1500

It is to be noted that the weight includes both passengers and baggage.

Mr. Litchfield further states that a tire should be reinflated when it has dropped 20 per cent below the recommended pressure. Also that the increase in pressure in a tire on a hot day does not very materially increase the pressure in the tire, but on the contrary that when a tire is pumped up by an engine-driven pump, by which I assume that a spark plug pump is intended, the heat of the air may increase the pressure from 15 to 20 lb. above what would be normal and that with such pumps the pressure ought to be tested an hour after the pumping has been completed.

It is evident that with a touring car, the passengers on the rear seat of which sit directly over the rear axle, a reduction of 10 lb. in pressure might ordinarily be made between the use of the car with the rear seat unoccupied and with the car loaded to its normal capacity, this difference making considerable difference in the comfort of those occupying the front seats on an extended trip. While on the contrary, if all of the seats were to be occupied on some occasion, prudence would suggest a test of the rear tires to make sure that they were properly inflated for the extra load.

Proper Sizes and Inflations

Roughly speaking, it would appear that a 3000-lb., five-passenger touring car should have 4½-in. tires inflated to 60 lb. For a 3600-lb. seven-passenger touring car, the 5-in. tires inflated to 70 lb. For a 4700-lb. seven-passenger touring car, 5½-in. tires inflated to 75 lb., and for a 5500-lb. seven-passenger touring car, 6-in. tires inflated to 75 lb.

No inflation above 75 lb. was recommended, although the carrying capacity of a 6-in. tire inflated to 100 lb. was given as 2280 lb. per wheel.

The Half-Inch Difference

It may be worth while for the reader to consider that when an automobile tire is in place on the machine it carries its share of the gross weight on a flattened section against the ground. This flattened contact with the ground is the shape of an elongated oval, possibly 2 in. wide by 6 in. long, more or less. If the weight sustained by the tire is 800 lb., the oval may have an area of approximately 10 sq. in., and the tire would then be inflated to 80 lb. pressure. In other words, each square inch in contact with the ground would be pressed upon by the earth to the extent of 80 lb., and on the other side, by the weight of the car exerted through the air pressure in the tire to an equal amount. The importance of an additional half inch in tire section is then readily apparent. It will amount to widening the flattened contact substantially the whole additional half inch along the whole of its 6-in. diameter, i.e. 3 full square inches. With 80 lb. pressure this amounts to 240 lb. per wheel, or 960 lb. of added capacity for support for the whole car. The extra ½ in. does not seem much at first thought, but worked out in this way its true importance appears. It also becomes more apparent why a lower air pressure and not a higher air pressure should be used with a larger tire. To produce substantially the same length of flattened oval, the 800 lb. assumed weight on the wheel is to be divided by 13 instead of 10, and the corresponding pressure would be approximately 60 lb.

Using Old Rear Tires in Front

Mr. Litchfield was not specific as to the increased mileage to be obtained by use of oversize tires, but as he speaks of removing from the rear wheels tires which are "almost worn out" and says that they may be run on the front wheels several thousand miles, it is evident that the mileage must be greatly increased. My own very limited experience indicates that it is not less than two or three times that guaranteed by the manufacturer. Of course it is assumed that the driver is reasonable in the use of his brakes and in his speed.

Some years ago it was generally customary for automobile manufacturers to set forth in connection with other details of their cars the weight of the car, but I understand that as there was no standard as to what the word "weight" meant the practice was discontinued, and that the S. A. E. is considering the standardizing of a definition as to weights, which will enable the manufacturers again to state this interesting detail. As a matter of fact, due to additional mechanism and particularly the electric starting systems, the average car for a year or two increased considerably in weight. Attention is again being turned toward the effort to reduce the weight as far as practicable.

Weight Is Important

The weight of the car is, however, as much a matter of interest as the dimensions of the bore and stroke of the engine. It is something which every intelligent purchaser wants to know and which every automobile salesman has at his tongue's end, if asked. A few cars now give prominence to the matter of weight in their advertising. It is to be hoped that this is the beginning of a return to the general stating of that very important item of information, without which it is quite impossible to intelligently consider the matter of the size of tires and the question of the advisability of the use of the oversize.

In conclusion perhaps it should be said that the standard rims admit only the placing of one size of tire and one oversize of tire on the same rim. If the weight of the car is such as to demand anything greater than the oversize, or if it is such that the maker has placed upon it the oversize tire, the only remedy will be the equipping of the wheels with rims suitable to the larger tire. What the diameter of such a tire would be will depend upon the diameter of the tire seat. A 32 by 3½ tire has a rim of 25 in. in diameter. If the oversize 33 by 4 is not sufficiently large then a rim for 34 by 4½ will fit the same seat. A 32 by 4 has a seat diameter of 24 in., which unfortunately cannot be mended. With a 34 by 4 the seat diameter is 26 in., and a change to a larger tire than the oversize will require 36 by 5.

Information respecting these rim sections is given in THE AUTOMOBILE for Nov. 25, 1915.

Loads and Inflations

It seems probable that with the gradual increase of information among automobile drivers as to tire inflation the tire companies will find it practicable to change their method and to issue generally a scale of inflations suitable for various loads. This doubtless would require the action of the S. A. E. in standardizing such a scale, and it will probably be the end of guaranteed tire mileage, for the excellent reason that anyone who cared for the preservation of his tires and adopted the suitable size and inflation would invariably so far exceed the guaranteed mileage as to make the guarantee a matter of entire indifference.

Under this new régime tire troubles and expense would cease to hold the prominent place they now have in the minds of automobile owners.

Gross Carrying Capacity of Goodyear Tires—In Pounds, Per Tire

Infl. Press.		Tire Section Diameter						
Cord	Fabric	3"	3½"	4"	4½"	5"	5½"	6"
27	30	250						
32	35	290	860					
36	40	335	410	500				
41	45	375	460	560	675			
45	50	415	515	625	750	875	1000	1140
50	55	460	565	690	825	960	1100	1255
54	60	500	615	750	900	1050	1200	1370
59	65		670	815	975	1135	1300	1480
63	70		720	875	1050	1225	1400	1595
68	75			940	1125	1310	1500	1710
72	80			1000	1200	1400	1600	1925
77	85				1275	1485	1700	1940
81	90				1350	1570	1800	2050
86	95					1660	1900	2165
90	100						2000	2280

Before pressure drops 20 per cent tire should be reinflated.

This table shows the carrying capacity of Goodyear tires, both cord and fabric, and the proper inflation pressures for any given load. Instead of specifying a certain pressure for different sized tires, the scale provides a pressure adjusted to the load the tire carries.

Standardized Body Design Is Possible

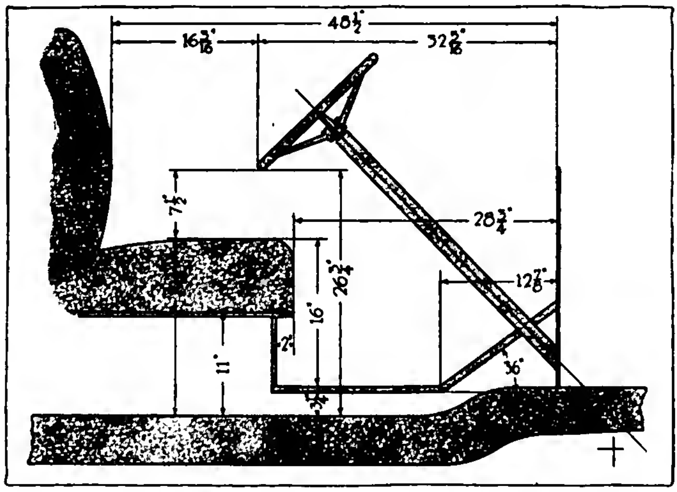
By H. L. Kupel

Bartholomew Co.

THE writer believes that the article in THE AUTOMOBILE for Feb. 3 is very timely as comparatively little attention has been paid to comfort in the past.

The various dimensions as given in the table in this article seem to work out very well after checking them over with our own car, but one dimension which is very important has been omitted, namely, the depth of the front cushion. The writer thinks it is the distance from the front seat back to the pedal that is of prime importance, and we find that for an average person the distance from the front seat back to the edge of the front cushion should be about 17 in. and the distance from the front edge of the seat cushion on a horizontal line to the pedal should be 19 in., as shown in your table. If, however, the front cushion is made of less depth, then the distance from the pedals to the edge of the front cushion should be greater.

I thoroughly agree with Mr. Schipper in the conclusions he has reached in the dimensions that should be maintained, and I think that a front compartment of a body so built will fit almost any ordinary-sized person. The dimensions in the table also are of such a nature that they will permit of slight modifications in order to conform to the peculiarities of certain body designs.



Driver's seat dimensions used for Pierce-Arrow bodies

Good Proportions on Grant

By Jas. M. Howe

Chief Engineer Grant Motor Co.

WE have read Mr. Schipper's article printed in your issue of Feb. 3 with a good deal of interest, and are inclosclosing our corresponding dimensions of the Grant six.

You will see in the main that these dimensions agree fairly close with those recommended. The noticeable variations being that both our front and rear seat heights are carried 13 in. instead of 14 in., using comparatively soft cushions.

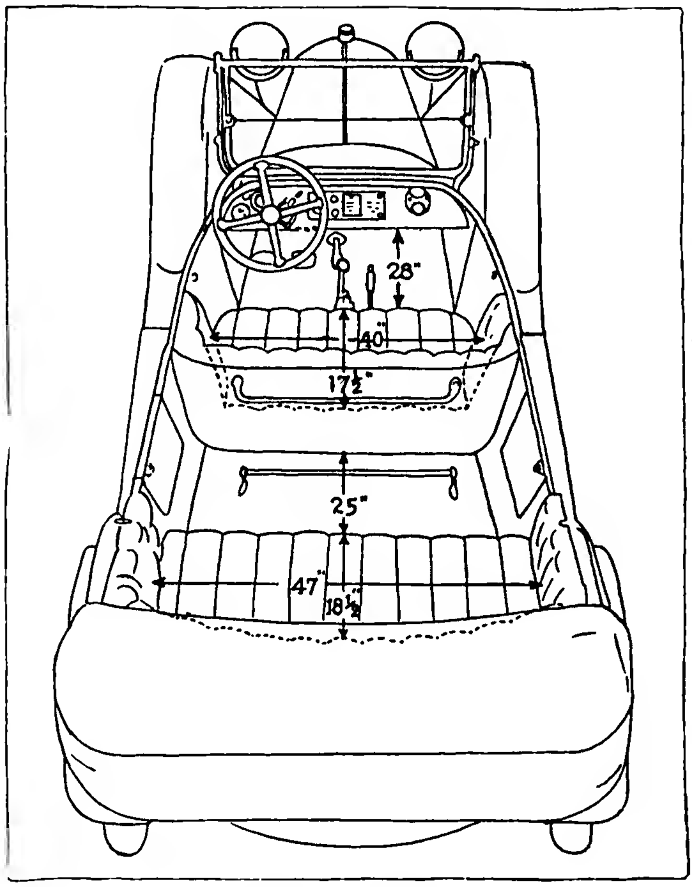
We believe that on a car of our size that 19-in. doors such as we have are ample. With this door we are able to secure a full door without cutting off the rear corner to clear the fenders. With a small six every inch in the length has to be watched very closely so that the space is employed to the best advantage. We have been able to hold our hood length down to 30½ in., which with our bull-nose type of radiator gives us the much-desired long hood appearance as well as a large body with this wheelbase.

In fixing the body dimensions we always set up a dummy and shift the various dimensions until the most comfortable position is obtained, striking a happy medium between the room required by a 6-ft. driver and a small woman. We find we are able to do this very nicely with the exception perhaps of our pedal distance. This is easily taken care of by an extension on the pedal, the other dimensions being comfortable for any size of driver.

There are a number of cars on the market to-day which the writer, who is over 6 ft. tall, is unable to drive with any comfort, the variations in dimensions being very clearly emphasized in the dimensions of the twelve cars that Mr. Schipper has checked up.

It has been our experience that a 21 in. or 22 in. depth of rear seat is too great, as a small person finds such a width uncomfortable. A good deal, of course, depends on exactly how the back is trimmed, but we favor the width of the rear seat not to exceed 19 in. or 20 in. The correct position we believe for the driver is leaning slightly back; the cushion should fit well in the small of his back.

In a number of cars the control levers are altogether too close to the front seat.



Proportions of Grant six

On the whole we feel that your recommendations as to dimensions are well chosen for comfort. With our dimensions we are able to employ the same chassis, with the exception of the rear springs, for our touring car, roadster and cabriolet, the driver's seat in the cabriolet and roadster being at these dimensions, while the seat for the other two occupants are shoved toward the rear 4 in. This works out nicely for three people.

Cast aluminum parts of the new Cadillac coupé body mentioned in The Automobile for Feb. 24

The Rostrum

More About Electrified Chamois Funnels

Editor The Automobile:—Considerable interest has been aroused among motorists by the publication of an article to the effect that the action of straining gasoline through a chamois generated a charge of static electricity sufficient at times to ignite the gasoline and cause disastrous results; and this article has been reprinted and given wide circulation by one of the automobile insurance companies.

In the interest of Marmon owners, the Service Department of Nordyke & Marmon Company have had this situation thoroughly investigated, and eminent authorities seem to agree that there is nothing whatever in the report that passing gasoline through a chamois generates an electrical charge.

In this connection, the report from Arthur L. Foley, head professor of physics at Indiana University, is of interest. Professor Foley writes as follows in answer to the Nordyke & Marmon Company's inquiry:

"Pouring gasoline through a funnel with chamois strainer does not of itself produce a charge, and it makes no difference whether the funnel is supported by a person or by the gas tank. The article is in error in saying that the funnel is grounded when in the tank, and insulated when in the hand. If there is insulation in either case it is more likely when the funnel is in the tank, as the car stands on rubber while the man usually does not.

"As a matter of fact there would be very rare cases, indeed, when both were not grounded for potentials sufficient to produce a spark. But on a day when the atmosphere is very dry as it is unsually on a cold, clear day, a man may become charged by scuffling about on a clean, dry floor, or his clothing may become electrified by friction, as noticed sometimes when combing the hair.

"Under such circumstances pouring gasoline through a funnel, whether or not there is any chamois in it, gives rise to induced charges that are quite too complicated to undertake to explain in a few words. Such charges might fire the gas. Indeed the original friction charge might do so under certain circumstances." P. F.

Indiana University.

Grant Six Dimensions

Part of Car	Key Letter on Chart	Dimension, Ins.
Wheel to front seat vertically	A	8½
Wheel to seat back, horizontally	B	16¼
Front seat, height, vertically	C	13
Shifter to seat, horizontally	D	7
Center of wheel height, vertically	E	27
Pedal to seat, horizontally	F	19½
Shifter level handle height	G	16
Brake lever to seat, horizontally	H	14
Level line of eye and wheel top	J	Over
Must one lean to shift gears	K	No
Must one lean to apply emergency	L	Slightly
Width of front door	M	19
Position of driver in seat	N	Slightly backward
Transverse distance sill to shifter	O	17
Transverse distance sill to brake	P	21
Width of front seat for driver only	Q	20
Entrance space between wheel and side	R	10
Front seat back to rear seat	S	29
Height of rear seat	T	13
Depth of rear seat	U	19
Width of rear seat	V	47
Width of rear door	W	19

Table of Grant six body dimensions which are mentioned in letter from Jas. M. Howe on opposite page

Reboring Cylinders Adds Life to Motor

Editor The Automobile:—I have a 1910 Hudson 20 motor number 1690. It has been thoroughly overhauled, all new bearings in motor with new helical timing gears. What is the make of this motor?

2—I would like your advice on reboring or regrinding cylinders and fitting now pistons.

3—I have never used a self starter but would like electric lights that will stand up while on or in use. Kindly give your advice on generator, etc.

I have used this car several thousand miles with very satisfactory service and I am rather attached to it and do not care to sell or give it away. C. B. F.

Brooklyn, N. Y.

—This motor was made by the Atlas Engine Works, Indianapolis, Ind. Any new parts for it can be secured from the Hudson factory in Detroit.

2—This would no doubt be worth while if the other parts of the car are in good condition.

3—You can install either a storage battery system alone or a generator and battery system. There are a large number of these now on the market which give very good satisfaction and the installation could be made at a moderate expense.

Wheels Gathered for Easy Steering

Editor The Automobile:—Why are the front wheels of an automobile ¼-in. further apart at the rear of the front wheels than at the front?

2—Would it make very much difference on the wear of a tire should this distance vary 1/16-in. either way?

3—If the front wheels are the same distance apart in front and rear, should the tire wear longer? If not so, state why.

4—Should the tire on a wheel that is not cambered give greater mileage than one on a wheel which is?

New York City. J. M. K.

—The slight gather in the wheels is for the purpose of easier steering and for the purpose of keeping the car in a straight course.

2—It would make a noticeable difference.

3—Yes, although the amount of wear due to the normal gather is not enough to be detected.

4—If by camber you mean inclination in the vertical plane, this makes no difference in mileage.

Plugs Must Withstand Heat and Current

Editor The Automobile:—What are the requirements of a first class spark plug, porcelain or stone?

2—How much heat must the insulation stand and how much current should it take to break down same?

Bridgeport, Conn. A. E. W.

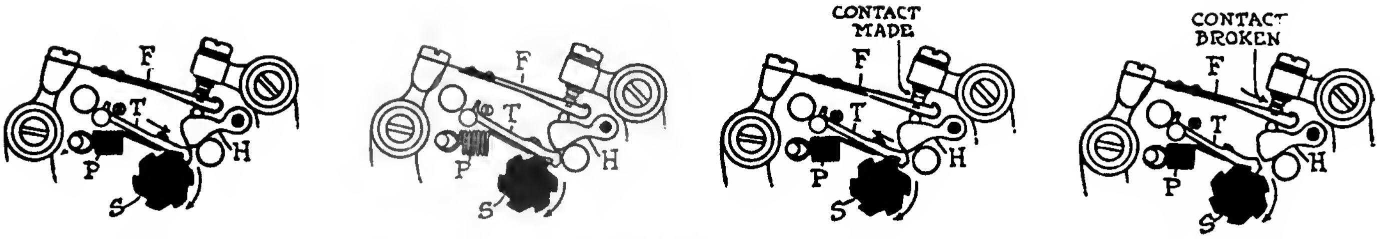


Fig. 1—Diagram showing the phases of operation of the Atwater Kent breaker mechanism and illustrating the open circuit system

—That the insulation does not leak, that the shell is not cracked by tightening the spark plug nut and that the plug does not foul or the points rapidly burn away.

2—The insulation should stand heat up to the temperature of red-hot iron and the dielectric strength must be at least 10 per cent above the possible electric pressure in the high tension system.

Speedster Body on 1915 Franklin Chassis

Editor The Automobile:—Would it be practical to put speedster body on a Franklin chassis 1915 model?

2—Would this outfit operate satisfactorily with a gear ratio of 3 to 1 on high and what speed would this give?

3—Would a Franklin motor be capable of sustaining speeds of 50 m.p.h. or better for any considerable length of time? F. S. W.

Ithaca, N. Y.

—It would be practical to put a speedster body on the 1915 Franklin chassis.

2—The gear ratio of 3 to 1 on high could be used satisfactorily but the speed that the car could make would depend altogether on the condition of the motor.

3—This again is a question of the motor which could no doubt be tuned up to fulfill these requirements.

Operation of the Atwater Kent Timer

Editor The Automobile:—Why is it that the Atwater Kent timer is said to work on the open circuit system; is it because of the way in which the circuit is broken? Kindly explain by diagram.

Philadelphia, Pa. H. R.

—The operation of the Atwater Kent circuit breaker is on the open circuit principle because there is no sustained primary circuit. The contact is made and broken immediately in contra-distinction to the closed circuit in which the contact is remade immediately after breaking.

The operation of the circuit breaker is shown in Fig. 1. The cam wheel *S* has as many notches as there are cylinders and every time one of these notches operates the tripping action an explosion occurs. The notches pull the piece *T* in the direction of rotation of *S*. The piece *T* rides up on the surface of the notch in *S* and finally slips off, being pulled back with a snap by the spring *P*. As it snaps back, the piece *T* strikes the part *H*, which in turn hammers against the spring *F*, making contact for the briefest possible interval. Contact is immediately broken and the circuit is again open.

Piston Displacement per Mile Measures Consumption

Editor The Automobile:—Is it possible to calculate with any degree of accuracy the gas consumption of a car, given the cylinder displacement, geat ratio, and wheel diameter? It seems to me there should be some very definite relation among these factors, yet the results I get from figuring do not tally at all with the actual road tests. What is wrong with my figures?

Thus:

My car, an Oakland, model 50, Northway motor of 346.4 cubic inches displacement, has a gear ratio on direct drive of 4:08 to 1; and 34 x 4½ tires. It is evident that in a mile of 5280 feet, the rear wheels will have to revolve approximately 593.25 times to cover the distance. The gear ratio being 4.08 to 1, the engine turns over approximately 2420 times in the same distance. Each time the engine turns over, one-half of the eight cylinders are fired, from which it appears that its total displacement of gas for this mile is 242.65 cubic feet, or 419,270 cubic inches.

Assuming that the mixture is 1.5 per cent gasoline vapor (the thinnest that can be depended on to explode), this would mean that approximately 3.64 cubic feet of gasoline vapor are required for the mile.

According to Sci. Am. Supp., Dec. 11, 1916, one gallon of gasoline, 70° Baume, gives 25 cubic feet of vapor. If this is true, then the actual miles-per-gallon of this car, figured on a volumetric basis, is less than 7½ miles to the gallon.

As a matter of fact, this car will do 12 miles to the gallon on a fairly level road, in actual practice.

Figuring the same proposition on another basis, that gasoline and air form an explosive mixture at the rate of 1 in 10,000, then 41.927 cubic inches of gasoline would be consumed in one mile. This gives a mileage of approximately 5.5 miles per gallon.

Let us go at the question in still another way: A gasoline engine giving a horsepower-hour on a pint of gasoline is considered an efficient engine. But how does this fit when applied to the case in point? At 2420 r.p.m., according to the above figures, my car travels 60 m.p.h. At 1210 r.p.m., it should travel at 30 m.p.h.

Now, according to the formula $\frac{D^2 N S R}{15,000}$ this motor should develop 35 hp. when running at 30 m.p.h. At a pint for each hp. hour, this would mean 35 pints of gasoline, or 4⅜ gallons, which gives us a mileage of 6.85 miles to the gallon. Again we are away off from road results.

The factors in the first example seem to be fixed, positively; the engine must turn over 4:08 times to each revolution of the rear wheels; and the engine must consume 173.2 cubic inches of gas at each revolution. So it seems. Yet only recently we were told that a Cadillac showed approximately 20 miles per gallon at 15 miles per hour, and only 6 or 7 miles per gallon at 60 miles per hour. Does the gas become richer at high speed? Carburetor engineers tell us they strike to make it thinner. Skin friction and inertia are at the maximum at high speeds. Then why is not volumetric efficiency higher with high speeds? Apparently, from the Cadillac and other tests, it is lower—practically varies in inverse proportion with miles-per-hour.

If this question is sound, I should like to see it discussed in The Automobile by some of your experts. If it is not sound, throw it away. I am one of a large body of your readers who, as automobile owners, without technical education, find in your magazine the final spice necessary to make perfect the joy of owning and operating and keeping their cars in good condition. Therefore, please tell me why my car is more efficient on the road than it is on paper.

New York City. A. I. A.

—In your first test where you have calculated the amount of gasoline drawn into the cylinder in a mile, there are two important factors which you have neglected. First, the amount of air used is far in excess of the theoretical combustion limit and if only the theoretical amount of air were admitted to the cylinder the mixture would be too rich for practical purposes. As all the oxygen in the air is not combined with the fuel in combustion, it has been found necessary to supply a considerable excess of oxygen in order that best results be obtained.

The second point you have omitted in your calculation is the volumetric efficiency of the motor. If this efficiency coefficient is 0.85 or 0.9 it is quite evident that you will get much less actual displacement per mile than you do theoretical.

On your second test you have calculated on a full throttle opening which is not the case always at 30 m.p.h. and certainly not with your car, if it is capable of traveling 30 m.p.h. Normally the amount of gas passed by the engine is between 0.3 and 0.7 the calculated total. The pressure of the atmosphere is insufficient to charge the cylinders fully during the short time the intake valve is open and also the exhaust gas left in the cylinder is a little above atmospheric pressure, so delaying the commencement of intake.

Non-Poppet T-Head Motor

Editor The Automobile:—Is it possible to have a motor of T-head cylinder shape without poppet valves? In order to do this it would be necessary to have sleeve valves on each side of the cylinder and I would like to know if this has ever been done.

New York City. C. G. S.

—The double-rotary valve shown in Fig. 2, is a good example of T-head motor without the poppet valves.

Timing of Model 19 Buick of 1910

Editor The Automobile:—Will you kindly give me a diagram showing the timing of a model 19 Buick? I think this car was built in 1910. F. D.

Warwick, N. Y.

—Model 19 Buick is properly timed when the piston is 1/16-in. past upper dead center and the inlet valve opens when the piston is 3/32-in. past upper dead center. These measurements should be taken with a clearance of 0.005 in. between the ends of the valve stems and rocker arms when both valves are fully closed.

These measurements are taken by removing one of the valve cages and measuring the piston travel in the cylinder with an ordinary scale.

Enger 6-50 Used Salisbury Axle

Editor The Automobile:—What make of rear axle did the Enger model 6-50 use in the 1915 cars?

2—What make clutch?

3—What transmission did they use in the 1912 Enger cars? J. F.

Wilkes-Barre, Pa.

—The Salisbury rear axle was used.

2—Mechanics Machine Co., multiple disk dry plate type.

3—Milwaukee unit power plant.

Velocity Depends on Motor Speed and Ratio

Editor The Automobile:—How can a machine with 4 sq. ft. of head resistance travel faster than one with 6 sq. ft. if the motor speeds are the same, as are also the weight of the machines, horsepower, gear ratios and size of wheels?

2—If the maximum speed of a motor is 4200 r.p.m. with gear ratios and horsepower the same in both instances, would reducing the head resistance increase the speed of the car? L. H. A.

Battle Creek, Mich.

—If the motor speeds are both *the same* and the gear ratios and size of wheels are both *the same* both machines must travel at the same speed regardless of *any* other factors.

2—If *the same* maximum motor speed is obtained the gear ratios being constant, the speeds must be equal, but neither the same maximum car speed nor the same *motor* speed would be obtained in two cars with different head resistance but otherwise identical.

Wear Varies with Pressure and Speed

Editor The Automobile:—Is the wear on a bearing in proportion to the square of the pressure?

2—Is the wear in proportion to the speed?

3—The Diesel engine seems to be an ideal engine judging from what I have read of it. Why are they not used in automobiles?

4—What are the objections to kerosene?

Jersey City, N. J. O. T.

—No, inversely as the square of the diameter.

2—Yes.

3—The satisfactory automobile unit has not been as yet evolved although there are many engineers who believe that the Diesel principle will be incorporated in the eventual automobile power plant.

4—It cannot be handled satisfactorily with the present methods of vaporization as employed in automobile practice. There is no doubt that the kerosene motor is not nearly so far off as its present absence would seem to indicate.

Car Should Travel 350 Miles to Gallon of Oil

Editor The Automobile:—Will you kindly answer the following questions on Studebaker Six, 1914?

1—How many miles should this car get on a gallon of gasoline with a lean mixture?

2—How many miles will this car get on a gallon of lubricating oil?

3—How can I lower the rake of the steering wheel and column, also the front seat, as I would like to sit about 3 or 5 in. lower. F. M.

Philadelphia, Pa.

—You should average in the neighborhood of 10 miles per gallon.

2—The Studebaker Corp. states that owners should get about 350 miles per gallon of oil.

3—It is suggested that you have a thinner front seat cushion made and an extension bracket for the steering post.

Motor Misses at Low Speeds

Editor The Automobile:—I have a 1914 Baby Grand Chevrolet. It misses at low speed whether running idle or pulling the car. The miss is approximately one shot out of

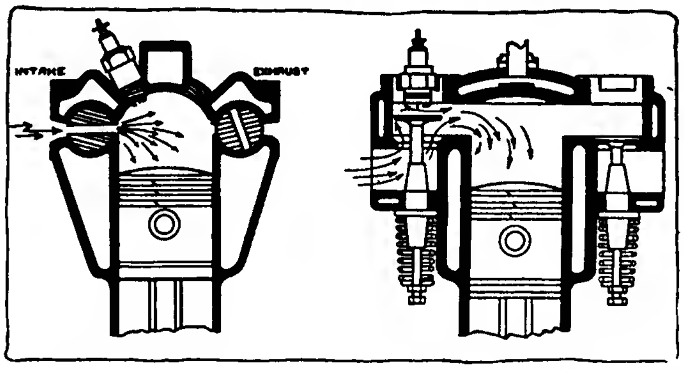

Fig. 2—T-head rotary and poppet motors, left is Mead type

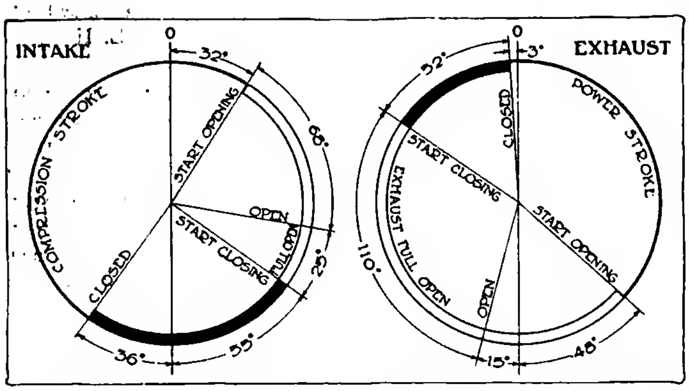

Fig. 3—Timing diagram showing intake opening delayed after exhaust closure

four. Sometimes two miss together, and there is nothing regular about it. After the car is running 20 m.p.h. and faster it runs perfectly and for all speeds higher. This has been acting so for nearly a year. It never refuses to go and starts very easily. I have installed a Schebler carbureter but to no great advantage. I have had it in shops all over central California, San Francisco included. F. H. E.

Woodbridge, Cal.

—It would seem that the ignition system was deranged in some way as to cause a momentary interruption in firing at scattered intervals and it is advised that this be overhauled. Eliminate spark plug considerations by trying a new set of plugs. Then borrow a new timer from another Chevrolet and try this. The same process may be used with each of the ignition units. Sometimes a loose part in a switch will cause uneven firing due to momentary interruption of the current. Faulty insulation or terminal connections give the same indications. Do all the valves close properly? If one should stick or hang up a few thousandths of an inch it would cause the trouble.

Late Intake Creates Vacuum in Cylinder

Editor The Automobile:—Why do some of the manufacturers leave the intake closed for some time after the exhaust valve is closed? Do they not cut down on volumetric efficiency by so doing? M. S.

Ilion, N. Y.

—The reason for the delayed opening of the intake is to create a vacuum in the cylinder which will cause the inlet gases to rush in and fill the cylinder. It takes a noticeable amount of suction to overcome the inertia of the gases and this vacuum is left for the purpose of overcoming this inertia. A diagram showing a late intake opening is illustrated in Fig. 3.

Offset Crankshaft Not Used Extensively

Editor The Automobile:—Has the offset crankshaft been discarded from four and six-cylinder engine design in the auto world?

2—Did not this feature tend to make a more compact motor and also to even up the pressure on the cylinder walls due to a greater connecting rod angularity on the up stroke and less angularity on the down stroke?

3—How does the Cothias process differ from conventional die casting practice?

4—Is the speed in r.p.m. used to designate a high speed motor its maximum speed or the speed at which maximum power is delivered? H. S.

Ann Arbor, Mich.

—Practically entirely, although there are a few still in use.

2—In practice this feature did not seem to give any noticeable advantages.

3—By the use of secret details which allow the use of aluminum, which contracts on cooling, instead of a babbitt, which expands.

4—Generally.

Mixed Fuels Are Generally Undesirable

Editor The Automobile:—Would it be feasible to mix kerosene with gasoline to use in a gasoline motor car providing the fuel is heated and a small jet of steam was let into the intake manifold? If so, about what proportion of gasoline and kerosene? H. C.

Riverton, N. J.

—It is better not to use a mixed fuel but rather one of lower gravity which would give the corresponding fuel. The jet of steam would hardly produce the desired results in automobile practice.

Parents Responsible for Minor's Action in Car

Editor The Automobile:—Please inform me if the owner of a car can collect damages if his car is run into while being driven by his son, who is not quite sixteen years of age, with his father's permission. The car was on the right side of the road when hit and was less than 4 ft. from curb. Road was 24 ft. wide. W. T. L. TB.

Newburgh, N. Y.

—While this is a matter for the courts to decide, it seems right that the father can collect damages. Not long ago, a father was compelled to pay damages for an accident which occurred while his son was driving the car without the father's permission. It seems reasonable that the law should work both ways.

Tire Sizes Used by Studebaker

Editor The Automobile:—Can you tell me the different size tires the different Studebaker cars take, from the first model up to the present ones? Also, the number of cars made by this corporation under the name of Studebaker from the first up to the present time or for the close of the year 1916, etc.? W. M. S.

Detroit, Mich.

—The table herewith gives you the size of tires used by the different model Studebakers from 1907 until the present date. It is impossible to state the annual output of the Studebaker company for all these years.

1907

Model	Tires
40 hp	34 x 4

Which Front Tire Wears First

Editor The Automobile:—Which will wear the longest, the right or left front tire under ordinary conditions? C. L. M.

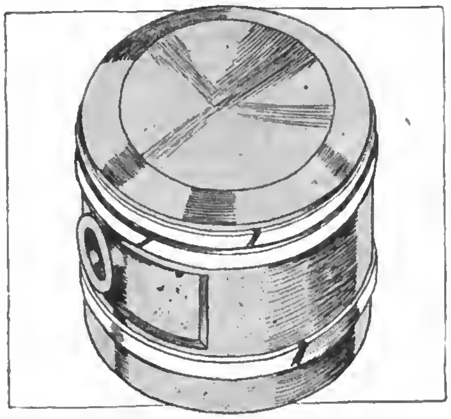
Osco, Ill.

—There will be very little difference in the wear of the two front tires. The fact that the driver usually sits on the left side and frequently is the only extra weight in the car would tend to cause slightly more wear on the left tire. On the other hand, the fact that most of the turns are made to the left, when turning around, would cause the right tire to travel the greatest distance, and, on this basis, it would wear more quickly. Taken all in all, the wear is about equal, in ordinary cases.

ACCESSORIES

Abcilium Alloy Pistons

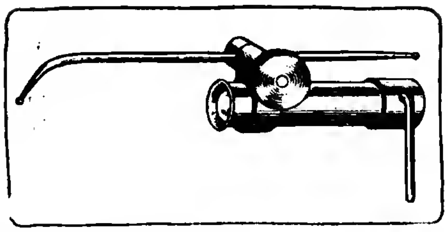
BY the use of the metal abcilium, pistons are obtained which are claimed by the manufacturer to be 70 per cent lighter than cast-iron pistons of the same size. A manufacturing feature of advantage is that the use of expensive dies is said to be unnecessary, the makers recommending sand-cast abcilium pistons, stating that their density is so great that each will withstand an hydraulic pressure of 80 to 100 lb. from within. This feature also eliminates the expense entailed by changing patterns, etc. Abcilium pistons are said to absorb oil under pressure, this oil oozing out again when the pressure is relieved. The maker declares that abcilium pistons have run for from 60,000 to 70,000 miles without showing signs of wear. Other advantages claimed for these pistons are: increased power, acceleration and speed with a corresponding decrease in fuel and upkeep expense; decrease of strain on crankshaft and connecting-rod bearings and bolts; reduction of carbon incrustation; and durability to the extent that none of the parts wear out of shape under severe service and extreme heat.—A. B. C. Castings Co., Cleveland, Ohio.



Abcilium aluminum alloy piston

Kander Test Indicator

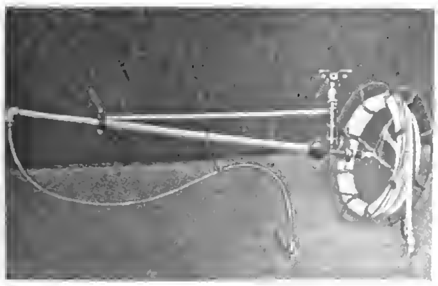
A pointer adjustably clamped on a metal tube containing a flash-light battery and a small bulb comprise this device. The instrument is so mounted, when in use, that the needle can be brought close to the surface of work running in the lathe or other machine tool. If there are high spots the pointer will touch them and thereby ground the lamp, which will flash and indicate the high spot. It sells for $2.50.—J. G. Kander, Reading, Pa.



Kander flashlight test indicator for machine work on lathes, etc.

Gaylord Combination Washers

This consists of a swivel washer, at one end of which is a hose reel carrying from 50 to 100 ft. of hose, which is connected with the water supply, and at the other end, a 10-ft. hose with an automatic spring valve at the nozzle. The water is turned on in the hose on the reel by pulling the hose. By the use of the two outlets, two men can work on a job at the same time; or the reeled hose may be kept for fire purposes, for which it is especially suitable because of the ease with which the water is turned on. A plain revolving washer is also made without the reel and automatic attachment at prices ranging from $12 to $30. Both types may be had with or without electric lights. Prices $25 to $50. —Gaylord Sanitary Mfg. Co., Rochester, N. Y.



Gaylord combination washer

Affinity Cleaner

No water is required in using this compound which is said to effectually clean oil and grease from the clothing and hands. It has a pleasant odor and is not injurious in any way according to the manufacturer.—Affinity Cleaner Co., Omaha, Neb.

Apco Fender Brace for Fords

The Apco fender brace, besides preventing the fenders of a Ford car from rattling, is designed to seal the space between them and the aprons. The brace is a heavy strip of pressed steel which fits well, being held in place by special screws which are easily attached. Besides increasing the rigidity of the fender, the brace prevents water, mud, etc., reaching the running-boards. Four of the braces comprise a set, including the screws, the finish being baked-on black enamel. The braces list at 50 cents.

The new Apco emergency brake handle for Fords is claimed to be an improvement over the ordinary handle in being more positive in action, fitting the hand, and in appearance. Complete with attachments and ready for fitting, it sells for 60 cents.—Auto Parts Co., Providence, R. I.

Pee-Gee Paint for Fords

The outfit consists of 1 qt. of flat black, 1 qt. of top black, 1 pt. of top dressing, coarse and fine sandpaper and a 2-in. brush. It sells for $3.—Peaslee-Gaulbert Co., Louisville, Ky.

Hansen Air Chucks

The Service chuck provides an automatic connection between air hose and valve stem and is fitted with a mushroom valve which is opened by the valve stem and which closes as soon as the chuck is removed from it. It lists at $3.

The Hansen hose connection is designed for smaller garages and use on portable tanks. It grips the valve stem by a soft rubber sleeve which prevents leakage. Price, 80 cents. The same connection may be had with a pressure gage and by pressing down on the gage the exact pressure in the tire may be read. Price, $2.—Hansen Mfg. Co., Cleveland, Ohio.

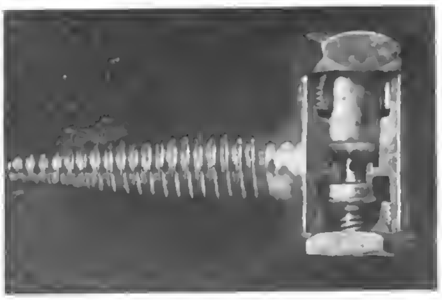
Lewis Nojar Clock

This clock is contained in a rubber case which protects it against road stocks and car vibration. Stem wound and guaranteed for two years, it is made for all makes of cars, the Ford model being attached to the steering wheel and selling for $2.50, while the others are put on the dash and sell for $3 each.—Pennsylvania Rubber Co., Jeannette, Pa.

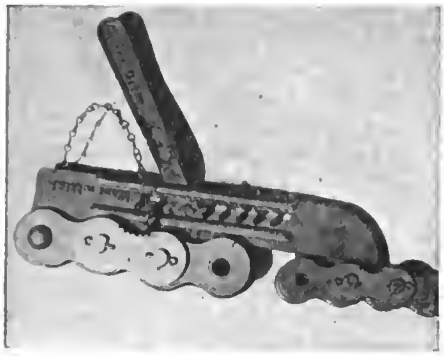
B-G Spark Plug

A spark plug that is unusual not only in outward appearance but in its internal construction is the B-G Non-shortable, recently placed on the market.

Two factors give the plug its outward novelty; it is copper plated for protection and to permit easy unscrewing when tightly set up and the wrench faces are



Hansen Service automatic air chuck



Meyer tool for repairing broken motor truck drive chains

carried high to give the wrench a chance when the plug is inserted in a deep recess.

As for the interior, the central electrode is not an ordinary metal rod, but is composed partly of a carbon compound packed into a recess in the porcelain. The manufacturers claim that this has the effect of greatly enlarging the spark and of so affecting its character that it will not short-circuit through a carbon deposit on the insulation. The porcelain is inclosed in a double bushing designed to overcome breakage at the shoulder. The plug is assembled with the main bushing and porcelain in place and melted metal is poured between the bushing and the porcelain, making a close fit and a firm support for the porcelain. The exposed part of the porcelain is corrugated to increase the surface area. Plugs are packed in a metal can with a ferrule to protect the points which, by the way, are of the highest grade meteor wire. All standard sizes, $1.50 each.—Batchelder-Gallant Co., Boston, Mass.

Queen City Portable Garages

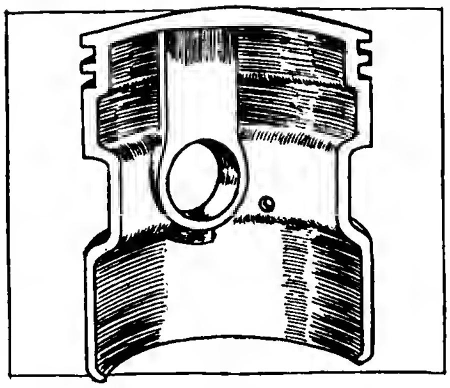
These garages are built of wood in sections and are put together with bolts, a wrench being the only tool required. Studding and rafters are of hemlock, siding of yellow pine and roofing of rubber; trim is white pine, doors glazed and paint may be of any color without extra charge. No floors are included. Price, 10 by 16 ft., $65; 18 by 16, with double door, $120.—Manufacturers Outlet Co., Buffalo, N. Y.

Meyer Chain Connector

It is always a great deal of trouble to bring the ends of a broken motor truck driving chain together, and it is practically impossible to draw the two ends together by hand in order to slip in the link pin. This prompted the invention of the Meyer chain connecting tool illustrated herewith in the act of drawing the ends of a broken chain together. The head of the tool terminates in a hook that is placed behind the first link and there is also a hook on the end of the lever, this catching the other end of the chain. Thus the slack in the chain is drawn up by the lever being moved forward from notch to notch in the main part of the tool, this working on the dog-and-ratchet principle. When the two parts of the chain are brought together, it is an easy matter to slip the pin in place. The device is made for small trucks at $2 and for large trucks at $3.—H. T. C. Meyer, Detroit, Mich.

Green Aluminite Pistons

These pistons are of an aluminum alloy, which, according to the makers, permits fitting with a clearance of 0.0014 per in. of diameter without danger of scoring even under hard conditions. The metal machines freely, has no pin holes and becomes glazed on the surface with a skin which is said to be better than that of cast iron. A feature is the use of stiffening ribs extending from the head to the piston pin bosses, having no connection, however, with the side walls. The effect of this arrangement is to minimize distortion through expansion.—Green Engineering Co., Dayton, Ohio.

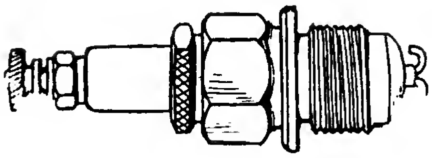


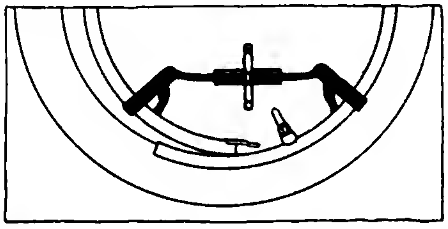
Green Aluminite piston construction

Niswander Rim Remover

This tool for removing demountable rims easily and rapidly contracts and expands the rim by a specially-threaded hand wheel. This gives an even, steady pull, contracting the rim from 1 to 4 in., and the rim hooks and braces are so constructed that the harder the pull, the tighter they grip the rim in either operation. The device folds to a length of 10 in., and although strongly made, it weighs but 2½ lb. and can be easily carried in the coat pocket. The rim hooks are of carbon steel and have sufficient spring to adjust themselves to rims of any width. Nickel-plating and high polish prevent the accumulation of rust. The maker guarantees the tool to work successfully on rims of any size or make. It sells for $3.—Niswander Mfg. Co., Quincy, Ill.

A Queen City portable garage





Above—3-X spark plug. Below—Niswander rim remover

3-X Spark Plugs

The 3-X is a heavy plug with steel shell and packing nut and blue porcelain insulation, the central electrode being split and turned back, forming two sparking points from which the current jumps to the surface at the end of the shell. The opening into the chamber back of the points is a small slot. The terminal at the top is of heavy brass and will take either spring clips or plain terminal tips. All regular and special sizes are made, selling for $1 each.—3-X Spark Plug Co., Chicago, Ill.

Giles Tire Valve

This is a tire valve which will perform all the functions of that part and will also take the place of a pressure gage. The Giles valve shows through a slot in its stem figures indicating the air pressure in the tire.

The valve itself is of the conventional type. The stem, however, is smaller in diameter than usual. A flat, thin-walled tube is coiled about it, the lower end of which is anchored while the upper end is left free with a dial attached.

The upper end of the tube is closed and the lower end communicates with the interior of the valve, thus being under the same pressure as the tire itself. The operation of the gage is the same as that of a steam gage, the pressure tends to uncoil the tube, and the dial is turned according to the pressure. The reading slot is placed at the top in the outer stem. Price, $1.25.—E. M. Giles, Peoria, Ill.

Laying the Foundation

BUILDING an industry, like building a nation, consists in rearing the structure of progress upon the foundations laid by the pioneers. It is to these pioneers and to their early experiments and environment that the heirs to the results of their work must turn from time to time to express gratitude for benefits received. Great sacrifices have always been made in foundation work.

Citizens of the United States have set apart certain days dedicated to those who have by their personal sacrifices, potential personalities and genius furthered the interests of their country. Every school boy is familiar with the names of the thirteen colonies that founded the great union which now spans the continent. Certain men and certain environments are beacon lights in the history of development and it is fitting to render expressions of recognition and gratitude to those patriots and to the scenes of their great activities.

Hardly second in importance to the building of a nation is the building of a gigantic industry which is of benefit to the entire world, constituting a very arc light illuminating the onward path of civilization. Just as the nation has its great founders who with wonderful foresight and determination lay down the lines of progress for the future, so has the industry its great pioneers who often made a life-long sacrifice to attain some little detail of advancement which has proved the key which has opened the gates to triumph in progress. Just as the nation has its hallowed ground upon which great deeds of war or peace were enacted, so has the industry its cherished localities where perhaps the cornerstones of great eras in development were laid.

To-day we turn to New England. Its history is the history of the country. New England, the scene of witchcraft and the whipping post, has had its darker days, but the accomplishments which have originated in that fair country and which are now reflected in its wealth and prosperity, in its wonderful manufacturing activity, are the rewards for the endeavors of the pioneers who have blazed the trail.

Cut the Gas Bill

EVERY experienced automobile man knows that, if they will take the trouble, users of cars can save a large proportion of their gasoline by taking proper precautions. At the present time, with gasoline at almost famine prices, it seems highly desirable that the subject of economy should be brought very forcibly before the user. The user of an automobile is in constant touch with dealers and garagemen, and in fairly close touch with the factories through their sales and service departments. This being the case, there is a great opportunity for the industry to educate the user so that he can reduce the fuel bill for his car.

There is no need to go into the matter in detail. A little skill allows the use of a far leaner mixture than is employed by the average man in ordinary running; keeping the valves, the ignition and the lubrication in proper order makes for efficiency and so saves power waste; care in one way or another is rewarded by the need for less gasoline to do a given mileage.

This is the most vital matter the industry has before it to-day. Never before have the men who act as "guide, philosopher and friend" to the user had to give close study to this economy question, but if they do not strongly buckle to just now, they will be failing in their duty and failing to grasp an opportunity for action which will react upon their own fortunes by giving the industry some very real assistance.

Every salesman and every dealer to-day ought to do all in his power to become an expert on the subject of saving gasoline, so that he can quickly, and accurately, furnish advice when it is sought. The day when the prospect's first question will be "how many miles to the gallon?" is not far distant, and the trade should, nay *must*, be prepared to give an answer that can be substantiated.

Nor should the automobile industry be content to let the matter rest there. Car manufacturers and engineers should redouble their efforts to reduce in every way possible to constructive and designing science the gasoline consumption of their cars. Everyone should realize that the matter is one which vitally concerns the continued success of the industry.

1915—Big Year for New England

Car, Truck and Accessory Factories in This Territory Break All Records

BOSTON, March 1—Taking inventory of the activity of the New England automobile, trucks, parts and accessory factories during the past year, the great increase in the industry and the unprecedented activity of the factories stand out conspicuously. All factories have been busy, and many parts manufacturers have operated on a 24-hr. schedule. Fully 100 per cent of New England manufacturers have increased production from 100 to 500 per cent, and 90 per cent of them have increased the factory facilities. In the vehicle field, Locomobile has had a particularly busy year with its truck work, and its car output has increased. Metz has added 160,000 sq. ft. to its factory at a cost of $300,000. Knox has expended a great deal of effort on its four-wheel tractor business. Stanley has increased its production.

Parts Field Active

In the parts and accessory field equal activity is found. The Connecticut Telephone & Electric Co. has added 40,000 sq. ft. manufacturing space at an expense of $50,000 and has added $25,000 equipment. The Pittsfield Spark Coil Co., formerly located at Dalton, is now located at Pittsfield with increased manufacturing facilities.

The New Departure Mfg. Co. has added a new building during the year and has others in process of erection. Fafnir Bearing Co. has doubled its manufacturing space.

The Waltham Watch Co. has made very great increases in its sale of clocks to the automobile trade.

Bausch Machine Tool Co. is adding a new building for the manufacture of worm drive units. The Heald Machine Co. has added a new building 300 ft. long for its grinding machines. Large increases in factory capacity have been made by the North Grinding Co. The Berkshire Magneto Co., a new organization, is practically ready to market its magneto.

The S. K. F. Ball Bearing Co. is building a new factory in Hartford. Rockwell-Drake Co. is erecting a new ball bearing factory at Plainville, Conn.

The Hartford Auto Parts Co. is erecting a new plant at New Britain. Additions have been made to the plant of the Royal Equipment Co. during the past year.

A new factory has been built during the year by the American Chain Co., in Bridgeport.

The Fisk Rubber Co. has been expanding manufacturing facilities by the erection of new buildings during the entire year.

The Bosch Magneto Co. has increased its manufacturing facilities by 60,000 sq. ft., the new building serving as an annex to the old factory.

The Auto Parts Co., Providence, has erected a complete new factory during the past year. The Mayo Radiator Co. has greatly increased production during the past year. The G & O Mfg. Co. started a new radiator business in New Haven a few months ago. Increased production has been made by the J & B Mfg. Co., Pittsfield, Mass., and also L. S. Starret, manufacturer of fine tools, Athol, Mass.

The Springfield Metal Body Co. has entirely reorganized with greatly increased capital, and is adding to its manufacturing facilities, to take care of factory business.

The Chelsea Clock Co. and the Boston Clock Co. have increased output and production facilities during the year.

Billings & Spencer, during the year, disposed of their old plant in Hartford and have occupied the factory of the Columbia Motor Co. and have added two new buildings.

Whitney Mfg. Co. has added an addition. Wyman & Gordon Co. has added to its forging facilities.

Norwalk Tire Co. has started during the year at Norwalk, Conn.

During the year the Boston Blacking Co., one of the largest manufacturers of shoe blacking, has entered the automobile field with a full line of automobile polishes, top dressings, etc.

The G. W. J. Murphy Co., Merrimac, Mass., maker of the Murphy curtain fastener, has secured a new plant at Amesbury, Mass., for immediate occupation, with ten-fold its present facilities.

L. P. C. Service Sold

RACINE, WIS., Feb. 28—The American Motors Co., Indianapolis, Ind., bid in the service and good will of the L. P. C. Motor Co., Racine, Wis., at the auction sale of the Racine company's assets ordered by the assignee, F. Lee Norton. It was the first parcel offered for sale and brought $3,400. The American Motors Co. will act as service house for all owners of L. P. C. cars in the future and will be in exclusive possession of repair parts.

Warner Gear Not in Merger

MUNCIE, IND., Feb. 25—R. P. Johnson, general manager of the Warner Gear Co., this city, states that the Warner Gear Co. is in no way concerned in the merger which was reported to be undergoing formation among Indiana concerns.

Dealer Wins in Horn Patent Suit

Court of Appeals Reverses Decision of Lower Tribunal in Klaxon vs. Oriental

NEW YORK CITY, Feb. 29—By a decree filed to-day in the U. S. circuit court of appeals for the second circuit, the decision of Judge Chatfield in favor of the Lovell-McConnell Mfg. Co. in its suit against the Oriental Rubber & Supply Co., has been reversed. Judge Chatfield's opinion, handed down last July in the U. S. district court for the southern district of New York, held the Hutchinson patent No. 1,120,057 valid and infringed by electric horns sold by the Oriental concern.

The patent in suit covers a construction having the drive shaft forming the axis of the electric motor at right angles to the plane of the diaphragm and slightly below the center. A face cam is used to vibrate the button at the center of the diaphragm.

Materials Market Unchanged

DETROIT, MICH., Feb. 28—Manufacturers of this city who were interviewed to-day see very little change in the condition of the general materials markets as compared with their status two weeks ago, when a general investigation was made. Most of them express the view that no relief from the current high prices of all raw materials is in sight. The recent German successes and talk of an early ending of the war should Verdun fall into the hands of the Kaiser's troops would not mean any bettering of prices for some months at least, until the producers could get reasonably caught up in their orders. However, such an outcome seems so remote that few if any of the Detroit automobile industry are taking such a long chance and are contracting now for deliveries well into 1917 at current prices. The feeling is quite general that the steel mills are taking as good care of the industry as could be expected under the existing circumstances.

In conversation with one of the largest carbureter makers, this manufacturer said that there seems to be even greater trouble in getting brass, which has heretofore been a necessity to carbureter production. However, his concern will soon be making nothing but malleable instruments, so the brass shortage will not effect him very much. This is a very interesting development of the material situation and indicates that the manufacturers are meeting conditions as they find them. There is no reason why malleable iron could not be used advantageously, but it took unprecedented conditions to force its development.

Wm. T. Jones, general manager of the Edmunds & Jones Mfg. Co., large maker of automobile lamps, whose principal requirements are brass, steel and glass, is one of those who does not see any immediate relief, although his company is in an enviable position due to having contracted as long as eighteen months ago for what materials would be needed this year. He states that the concern now has in stock five times as much material as one year ago, this serving to indicate the foresight displayed in many of the big factories. As a result, current high prices are not felt, but as there does not seem to be any tendency to lower prices, Mr. Jones said that they are now contracting for supplies for delivery during the second quarter of 1917. In normal times it would not be necessary to figure more than sixty days ahead, he explained, but now it is necessary to look twelve months ahead on steel. The conditions are not quite so bad for brass deliveries, however. It is easier to get glass than many other products, according to Mr. Jones.

Everything Going Up

Others of the big parts makers here, as well as the car manufacturers, see no great change, and, as J. E. Ryan, purchasing agent of the Russel Motor Axle Co., put it, everything seems to be on the up grade. He looks for no big drop for some time, at any rate not until the mills get reasonably caught up in their orders. It is next to impossible to contract for brass and copper, because it would not be advisable with the market so high and somewhat subject to fluctuations.

F. C. Gilbert, sales manager of the Timken-Detroit Axle Co., also stated that the steel market is higher and wilder.

It looks as if conditions would become even more strained than they have been, and while the Timken company is protected on steel and has been able to protect its customers. the steel mills are not able to give prices after next July delivery. The mills, he said, will protect on tonnage, but they are unable to say what the price will be.

The fact was also emphasized that car makers, dealers and the general public must fully meet the conditions and realize that prices for motor vehicles must go up, if quality is to be maintained. There is very evidently no way out of it. It is surprising how unanimous well-informed automobile men here are on this point.

Dividends Declared

Packard Motor Car Co.; quarterly of 1¾ per cent on preferred, payable March 15 to stock of record Feb. 29.

Kardo Axle Suit Re-Opened

Ohio Court of Appeals Upholds Corporation's Validity and Orders Rehearing

CLEVELAND, OHIO, Feb. 29—The decision of Judge J. H. Clarke of the United States district court of Ohio in dismissing on April 13, 1915, the patent infringement suit brought by the Kardo Co. against Henry J. Adams, dealing as the Reo Motor Sales Co., this city, has been reversed by Judge Hollister, sitting in the Federal court of appeals. Judge Hollister held that the Kardo Co. is a good corporation under the laws of Ohio and therefore has a right to bring suit for alleged patent infringement. He remanded the case to the lower court for rehearing of the patent claims.

This decision practically re-opens the case which has been in the courts now for over a year, and the higher court instructs that the lower court confine its decision to the merits of the patent in question. The Kardo Co. brought suit against Adams on Jan. 29, 1915, substituting for the American Ball Bearing Co., and charging infringement of patent No. 792,690 issued to Alanson P. Brush of Detroit by the use of a compensating mechanism termed a floating spider in the bevel gear of the rear axle of Reo cars. The Kardo Co. fell heir to the suit against the Reo representative when it took over the patents of the American Ball Bearing Co. The bill of complaint was filed June 25, 1913, and the case was transferred to Kardo on Oct. 3, 1914.

De Palma Becomes a Manufacturer

DETROIT, MICH., Feb. 28—Ralph De Palma is one of the incorporators of the De Palma Mfg. Co., which has been organized here with a capital stock of $100,000. The others interested with the famous race driver are Frank P. Book and J. B. Book, Jr., wealthy Detroiters. While the incorporation papers state that the new company will build aeroplane engines as well as racing cars, the main purpose at the present time is to campaign De Palma's Mercedes which gave such a good account of itself last year. The De Palma company will enter the Mercedes in the big race meets of the year, according to present plans, and Ralph is now busily rebuilding it at the present time here.

The officers of the De Palma company are: F. P. Book, president; Ralph De Palma, vice-president and general manager, and H. V. Book.

Although H. V. Book does not appear in the incorporation papers, he will be the secretary and treasurer when he becomes of legal age two months hence. J. B. Book, Jr., owing to the fact that his brother is not yet of legal age is therefore the third incorporator, although he will have no active interest in the company. All the stock of the concern is subscribed for, and there is none for sale, the incorporators wishing this to be made clear in view of the fact that they have already been approached by parties wishing to become interested.

Scripps-Booth Reorganized—Incorporated with $1,000,000 Capital

DETROIT, MICH., Feb. 28—A reorganization of the Scripps-Booth Co. has been effected, the company having increased its capital stock to $1,000,000 and incorporated under the laws of Delaware.

Clarence H. Booth, who became associated with the concern last December and who has been vice-president and sales director, has been made president; William E. Scripps, vice-president; James S. Booth, secretary, and F. J. Sensenbrenner, treasurer.

Of the new capital stock $750,000 has been subscribed and paid in while the balance of $250,000 is being held in the treasury for future needs.

Need for Testing Argued by Metro. Section S. A. E.

NEW YORK CITY, Feb. 25—At the regular February meeting of the Metropolitan Section, Society of Automobile Engineers, held at the Automobile Club of America last night, Leonard Kebler, president the Ward Leonard Electric Co., was elected chairman; Harry Tipper, advertising manager, Texas Co., secretary, and H. G. McComb, engineer the General Vehicle Co., treasurer.

The program for the evening included a symposium on motor testing and was provocative of a valuable discussion on the real needs of testing commercially. The topic was introduced by Peter Payne Dean, former engineer of the Diehl Mfg. Co., who took the viewpoint that it is not necessary to secure horsepower readings at the rear wheels.

This viewpoint was discussed by C. F. Scott, engineer of the Sprague Electric Wks. and others. The net result of the discussion seemed to be that some form of testing is necessary, but there was evidently a disagreement among the members present as to whether or not the expense of the dynamometer equipment is justified.

In bringing forward his arguments Mr. Dean stated that in his opinion the blower system fits the situation best of all, assuming of course that the accurate horsepower at the rear wheels is not to be measured accurately. The movement of the air in absorbing power does not create heat and furthermore the installation is not expensive. The air can be used to cool the radiator and thus simulate the actual conditions of running the car. In a modern installation, a series of multivane or paddle-wheel blowers are installed either in the test room ceiling or underneath the floor. They can be either driven through friction drums or by belt. This installation is now in use at the Chevrolet plant.

Mr. Dean stated that on comparing costs he finds that the electric dynamometer system to absorb 25 hp. would cost $800 per set, while the blower system for the same power output could be installed for $300 per set.

Knobloch Becomes Cole Motor Car Co. General Manager

INDIANAPOLIS, IND., Feb. 25—A. F. Knobloch has become general manager of the Cole Motor Car Co., this city. Mr. Knobloch was formerly general manager of the Northway Motor & Mfg. Co. He has also brought into the Cole company his brother. W. H. Knobloch, and A. Keller, an efficiency engineer.

Elgin Contest Board Chosen

Chicago, Feb. 28.—W. O. Duntley, recently elected president of the Chicago Automobile Club, has appointed the following members to serve on the contest board, which will direct the promotion of the Elgin road races, the Chicago speedway events and the annual inter-club reliability matches during 1916:

George Ballou, chairman; Joseph Callendar, Tom Hay, A. M. Robbins and E. C. Patterson. This committee will have as its advisors David Beecroft, editor of Motor Age and Automobile, and C. G. Sinsabaugh.

The new contest board promises to be a very active and efficient committee. Chairman Ballou served in the same capacity last year and the other members are experienced in racing matters. Callendar was head of the C. A. C. contest board in 1914, Hay has been starter for the Indianapolis international sweepstakes for the past 3 years, Robbins at one time was a driver on the Abbott-Detroit team and Patterson is the backer of Ralph de Palma.

The C. A. C. contest board has a most strenuous season ahead, as it will be in charge of the Elgin road races, the three meets to be held on the speedway and at least three reliability runs.

Fostoria Price Fixed at $675

FOSTORIA, OHIO, Feb. 28—The price of the new Fostoria light car has been fixed at $675. It has 108-in. wheelbase and the engine is 27 hp. Roadsters, coupes, speedsters and delivery wagons, ranging in price from $495 to $825, are built on the same chassis. These cars are manufactured by the Fostoria Light Car Co., this city.

Studebaker Earns $9,067,425

Sales Amount to $56,539,006, a Net Gain of $13,094,782—46,845 Cars Sold

SOUTH BEND, IND., Feb. 26—The fifth annual report of the Studebaker Corp. for the year ending Dec. 31, 1915, shows net sales of $56,539,006.23, as compared with $4,344,223.41 in 1914, a gain of $13,094,782.82, or 30.1 per cent. An increase of 87.2 per cent was made in net profits, after reserving an increased amount for depreciation and after payment of interest. Net profits for the year amounted to $9,067,425.28 as against $4,844,663.73 in 1914, a gain of $422,761.55. Deducting the payment of the 7 per cent dividends on preferred stock, the net profits remaining for the common stock amounted to 29.5 per cent during 1915 as against 14.2 per cent in 1914 based on a total of $27,931,600 common stock which was outstanding during all of 1914 and for eleven months of 1915.

War order sales amounted to only one-quarter of the total sales made last year, the amount being $13,000,000 as against $2,000,000 in 1914. Sales of cars have increased over 100 per cent since 1911, when only 22,555 automobiles were sold, whereas last year 46,845 were sold, over 90 per cent of which were delivered to regular customers in the United States and the remainder to regular customers in export markets. About 1300 of these were sold to foreign governments for hospital and other purposes.

The number of cars turned out last year year was 32.1 per cent greater than in 1914, but the volume of the automobile sales showed an increase of only 17.5 per cent on account of the reductions in the prices of Studebaker cars made last summer.

The net expenditures for plant and property in 1915 were $740,444 and depreciation credits were $397,991. In addition to these expenditures charged to capital there was spent for repairs and renewals and charged off to operating expenses $1,244,207, compared with $802,458 spent for the same purposes in 1914. The net working capital on Dec. 31 last was $21,276,837, an increase of $6,505,686.

Gasoline Prices Soar in Europe

Sells at 45 Cents Per Gallon in London District—Doubles in 3 Years

PARIS, Feb. 15—Gasoline has taken another leap in both France and England. In London district it is now selling retail at 2s. 6d. per gallon, which at present rate of exchange is equivalent to 45 cents per American gallon. This is the highest price in the history of England, and the highest price in European countries, Germany excepted. The direct result of this increase has been a curtailment of motoring; the use of cars for any other than utilitarian purposes is very small indeed. As, however, the use of automobiles in Great Britain for business and professional purposes is very extensive, the high cost of gasoline has called forth loud-voiced protests. Before the war, and before the government put a tax on gasoline, it was selling in England at 1s. 2d., or 28 cents per gallon; thus the price has more than doubled in a period of three years. There is considerable resentment against the few companies controlling the gasoline situation in England, motorists considering that the increased selling price is altogether out of proportion to the increase in freight and insurance. There is no doubt that when normal conditions are again established there will be a very strong feeling in favor of the use of benzole in place of gasoline. There is not much possibility of the rise of alcohol as an automobile fuel in England.

44 Cents in France

France has also had to stand for a rise in the price of gasoline, the refiners recently having decided to put $1 per 100 liters on gasoline and 60 cents on kerosene. The retail price averages 42.5 to 44 cents per American gallon. This excludes the city of Paris, where there is a special local tax artificially increasing the price of gasoline. For the first time in the history of motordom gasoline is cheaper in France than it is in England. This is partly explained by the fact that in England a government tax has been placed on gasoline, while in France the tax has undergone no change.

A Government Inquiry

The situation in France is considered so serious that a sub-commission of the Ministry of Commerce has been entrusted with an inquiry. This commission met the refiners before the present rise went into effect and was able to arrange that the price of kerosene should only be increased 3 francs (60 cents) instead of 5 francs ($1) per 100 liters. The projected increase in the wholesale price of gasoline was carried through, however, with a provision that in case the retailers' increase was disproportionate to the wholesale increase the refiners would undertake to sell to any municipal authorities at wholesale rates.

Grant-Lees Gear Co.'s Output Increases Over 400 per Cent

CLEVELAND, OHIO, Feb. 26—The output of the Grant-Lees Gear Co., East Sixty-ninth Street, this city, has increased over 400 per cent in the last three years. The capacity of the factory is now 120 complete transmissions per day, and the company is furnishing transmissions for some of the best automobiles in the country. Three years ago the company did largely a jobbing business in gears, but after a study of conditions in the industry experts in gear work were secured and the present flourishing business was started on its way.

Reliance Engineering Extends Scope

LANSING, MICH., Feb. 26—A further extension of the Reliance Engineering Co. has tagen place. The National Engineering Co., Saginaw, Mich., one of the largest grinding and finishing concerns in the country, has been bought out and its entire equipment of machines, tools, etc., also its entire working force of more than 100 men, will locate here in the plant formerly occupied by the Olds Gasoline Engine Co., which belongs to the Reliance interests.

The Reliance company has taken over about half a dozen manufacturing concerns during the past six months, among them the Seager Engine Works, the Michigan Crank Shaft Co. being the biggest. Further extensions of the Reliance company are likely to take place this year.

General Motors Output Statistics

NEW YORK CITY, Feb. 28—The number of cars and trucks built by the General Motors Co. during the six months up to Jan. 31, 1916, was 62,468, compared with 31,608 in the 1915 period, and 76,068 cars for the year ending July 31, 1915.

New York Chalmers to Move

NEW YORK CITY, Feb. 24—The Chalmers Motor Co., Detroit, Mich., has leased for the local branch the Wendel Building on the northwest corner of Broadway and Fiftieth Street, this city. It is a three-story structure. It is stated that two or three more stories will be added.

Name Now Johnson Bronze Co.

NEW CASTLE, PA., March 1—The American Car & Ship Hardware Mfg. Co., this city, has changed its name to the Johnson Bronze Co., with its main office and factory in this city. Its plant is being enlarged.

Porporato Called to Colors

Racing Driver Now in Italian Ambulance Corps—Other Drivers in Service

PARIS, Feb. 28—Jean Porporato, whose Sunbeam took second place at Chicago last year, and who is a well-known figure on American race tracks, has had to obey the martial call and is now wearing the uniform of an Italian soldier. Although Porporato became mechanically interested in automobiles as soon as he left school, and has been race driver and tester for Minerva, Gregoire, Berliet, Sunbeam, F. R. P., and other firms, the military authorities have placed him in the ambulance corps, with which body he is now serving on the Italian front.

After nearly eighteen months' service as an automobile driver on the French front, during which period he has had numerous miraculous escapes, Albert Guyot has just been transferred to the aviation section of the French army. Guyot learned to fly years ago, being one of the first men to mount a Bleriot monoplane, but nevertheless did not find it an easy matter to get a transfer from one branch of the army to another. He is now pilot of a Nieuport scout machine, capable of 120 miles an hour, his dangerous and exciting job being the bringing down of German machines which venture over the French lines.

Kennington to Leave for England Early in April

NEW YORK CITY, March 1—W. O. Kennington, for the past five years assistant chief engineer of the Remy Electric Co., will leave with his family for England the fore part of April. Mr. Kennington is offering his services to the War Office but as yet has not been assigned to any definite post.

He has been in America for about seven and a half years, coming from the English-Simms to the American-Simms and thence to the Remy company, and has been with the latter for about five years.

Mr. Kennington is engaging in business with W. H. Johnson, who is the European agent for the Remy company.

Murray Mfg. Gets Kemiweld Plant

DETROIT, MICH., Feb. 26—The J. W. Murray Mfg. Co., which makes sheet metal parts for automobiles, and which is now located on Clay Avenue, has acquired the Kemiweld plant of the Detroit Can Co., and will locate there shortly. It will provide much larger manufacturing space, and the Murray company intends to add a large force of men.

Louisville Show Success Spells Splendid Sales Season in South for 1916

Hundreds of Optimistic Dealers from All Parts of Kentucky and Southern Indiana Visit Show—30% Business Gain Over 1915 and 30,000-Car Registration Predicted

LOUISVILLE, KY., Feb. 26—Optimism is in evidence everywhere at the ninth annual exhibition of the Louisville Automobile Dealers' Assn., which opened last Monday evening and closes to-night. Indications point to a splendid season following the show. It is the largest motor exposition to hold attention south of the Ohio river, and, as usual, is staged in the First Regiment Armory, which covers 54,000 sq. ft. of floorspace. The big military building is one of the leading show places of its kind in the country, there being no pillars to obstruct the view. It presents a most attractive appearance.

43 Exhibitors

Forty-three exhibitors are showing forty-one different makes of gasoline passenger cars, twenty-eight more than last year, four electrics and nine commercial vehicles. The Old Hickory truck, built by the Kentucky Wagon Mfg. Co., a local concern, and the Dixie passenger car, made by the Dixie Motor Car Co., at the plant of the Kentucky Wagon Mfg. Co., are displayed for the first time at a show this season.

Many Dealers at Show

Factory representatives from all of the big automobile centers are in attendance. Hundreds of dealers from all parts of Kentucky and Southern Indiana also are daily visitors at the show. While the local exhibition, in the main, is a retail proposition, the Louisville distributors and factory representatives have closed many new contracts with sub-agents and dealers for the coming year.

One of the features of the Louisville Show is the great interest being manifested in the commercial vehicle by Kentucky merchants and manufacturers who are buying more trucks than ever before.

30% Gain Over 1915

Business is much better than it was at this time last year. A conservative estimate, based on interviews with dealers, points to an increase of about 30 per cent so far this year over the same period in 1915. A few dealers say business is 50 per cent better, but this is the exception rather than the rule.

Owing to the tendency of some of the dealers to keep their sales secret, it is impossible to give any figures as to the number of cars sold during the show, but all of them agree with the prediction of an official of the Commissioner of Motor Vehicles' office that 10,000 new cars will be sold in Kentucky during 1916. Some say that 15,000 automobiles will be sold in the State this year.

THE STANDING OF KENTUCKY AMONG THE FOLLOWING SOUTHERN STATES IN FIELD CROPS AND LIVE STOCK

Kentucky, Tennessee, Virginia, South Carolina, North Carolina, Florida, Alabama, Arkansas and Louisiana

Hay and forage, tons, 674,000	Third

In Louisville, sixty-three different makes of cars are handled by forty-two dealers and distributors. There are approximately 620 dealers and agents in the Bluegrass State, including about 180 Ford agents, 100 Overland agents and seventy-five Buick agents.

A Wide Territory

Louisville's show is the greatest motor event of the year in Kentucky and marks the opening of the selling season in this section of the country. The district embraced by the local agents, factory representatives and branches, as a rule, covers Southern Indiana, the entire State of Kentucky, and in some instances Tennessee, the western portions of West Virginia and Virginia.

Louisville is an automobile city, not in the producing sense, but from the standpoint of use and distribution. As a distributing point, with its excellent railroad facilities, it ranks with the leaders. A number of the largest factories and tire concerns in the United States maintain branches here.

The majority of dealers have a larger list of live prospects, who have promised to sign up in the spring, than ever before. The lack of deliveries has cost several dealers good sales. As a rule, the Southerner is slow to make up his mind upon the question of buying a car, but, once settled, he wants the machine immediately. When he can't get a certain make he wants, he visits another garage and finds another car in the same class that will satisfy him.

Trucks Sales Increase

There is one feature that stands out more prominently than any other in connection with the industry in Louisville, that is, the rapid strides which the commercial vehicles have made in popularity and usefulness. The number of horse-drawn vehicles on the streets is fast diminishing.

It is outside of the cities where local distributors are doing the bulk of their business. The farmers—the majority of them—and the people living the small towns, want a car selling in the neighborhood of $1,000, and they prefer a touring car, though there is a demand for the runabout. The car listed for $800 and under finds a ready market South of the Ohio River, provided it has a well-known company behind it.

50% Gain Predicted

The automobile in Kentucky has experienced its most prosperous year. During the year 1915, and to date in 1916, there has been a greater percentage of increase in automobile registrations than ever before. Five years ago an increase of 100 per cent meant about 2500 cars; to-day it means 20,000. The prediction is made from the Commissioner of Motor Vehicles' office that the Bluegrass State will absorb 50 per cent more cars during 1916 than in 1915.

The prospects are that 30,000 motor vehicles will be registered in Kentucky by Jan. 1, 1917. There is not a county in the State that does not register automobiles to-day, although 1915 is the first year to show this. Better roads throughout the State, and the Dixie and Jackson Highway movements are believed to be responsible in a large measure for the sale of thousands of cars.

The total State registration for the year 1915 was 19,500 automobiles and trucks, the fees collected amounting to $114,184.07.

10,000 New Cars

Hugh Ramsey, Deputy Commissioner of Motor Vehicles, who is an authority on the Kentucky automobile situation, says:

"About 10,000 new cars were registered during 1915, which paid only the proportional part of the fee to Jan. 1, 1916. These cars will pay the full fee, averaging $7.50, making a total of $150,000 for 1916. Over 1500 cars have been registered for 1916 to date, and a sale of 10,000 cars is anticipated for the year, which will contribute $50,000 in license fees, making an estimated total of $200,000 for the year on automobiles alone. This is more than one-third of the money derived from the so-called '5-cent tax.' There has been more money collected in one week in 1916 than the entire year of 1910. The total receipts for the month of January were $90,384, against $36,000 for the same period in 1915. If this proportionate increase is maintained through the year the estimate of $200,000 will be largely exceeded."

The increase in numbers in the State is largely due to the purchase of small cars in the rural communities. The year saw the advent of the jitney bus, and probably a few hundred registrations were due to that, but they have not had the effect predicted. There seems to be some cause for alarm by the railroad systems over the inroads on their passenger business by the automobile. Instructions have been issued by the larger systems to gather all information possible bearing on the question, in an effort to determine to what extent it menaces, and to work out, if possible, a remedy.

Louisville's Importance

The estimated population of Louisville proper to-day is 305,000; within a 10-mile radius, 416,000. The city is admittedly the largest exporting center in the world for tobaccos and whiskies. It is the largest grain market in the country outside of Chicago—especially for bona fide transactions—as well as the largest live stock market, especially in the matter of sheep and lambs, while in the matter of Southern fruit distribution, including pineapples, watermelons and the like, it is the most important in the United States. This city also is the principal mahogany market and manufacturing center in America.

With possibly one exception, Louisville is the largest exporter of agricultural implements in the world. Other great industries here are: porcelain-lined bath tubs, chewing gum, cotton seed oil, cotton seed products, organs, window shades, loose leaf ledger supplies, boxes, barrels, millinery, stoves, hardware, cement, paints and varnishes.

Record Clearing Reports

Total exchanges through the Louisville Clearing-house for 1915 established a new high record. The total for the year was $742,390,281, as compared with $667,947,515 in 1914, an increase of $74,442,766. Clearings for the closing month of the year amounted to $78,535,342, the highest record for a month in the history of the clearing-house, and a gain of $26,000,000 as compared with the corresponding month in 1914. For the last quarter of the year clearings aggregated $218,230,782, as compared with $146,858,562 for the same quarter of 1914.

Some Kentucky Statistics

Kentucky, with a gross area of 40,598 square miles, had a population in 1910 of 2,289,905. It ranked fourteenth among the forty-nine states and territories. According to the latest estimate of the census bureau, for Jan. 1, 1916, the State now has 2,372,412 inhabitants.

In 1909, from the last government figures available, the total value of the manufactures of the State, exclusive of the products of the neighborhood and hand industries, amounted to $223,754,000.

Kentucky, because of immense whisky production, pays Uncle Sam the fourth largest revenue in the United States. Of the total of $33,653,848 paid by this State in 1915, according to the Internal Revenue Commissioner's report, the biggest item was $28,642,911 from distilled spirits, this being about one-fifth of the amount collected from this source for the whole country. In addition to this, fermented liquor paid nearly $1,000,000 to the Internal Revenue Department in 1915.

$125,000,000 in Distilleries

These figures to some extent give an idea of the importance of liquor-making in a State famous from its earliest days for this industry. It is estimated that over $60,000,000 has been spent in distillery and brewery property in this State. It is further estimated that the operating capital of Kentucky distilleries aggregates something like $125,000,000.

The report of the United States Department of Agriculture estimated the 1915 tobacco crop in Kentucky at $27,899,200. Tobacco to-day is selling from 1 to 4 cents higher than it was a year ago.

This means prosperity in Kentucky, for tobacco is one of the State's chief products, and there is no question but what a big tobacco business influences the sale of automobiles and results in a greater demand for cars.

Texas Dealers Confer on New Law

DALLAS, TEX., Feb. 26—Future contracts of automobile general agents and subdealers over the State will eliminate territorial specifications and price stipulations. This it is said is the result of a conference at Austin last week with the attorney general for Texas and Dallas automobile dealers.

J. W. Atwood of the Buick company, who headed the aggregation of automobile dealers, said that the matter with the attorney general was amicably settled. Heretofore the contracts, some of them specified the territory an agent should sell in and the price he should receive for the car. These objections were raised by the attorney general.

This conference at Austin resulted in the filing of a number of suits against automobile concerns in which it was alleged the anti-trust laws of Texas were being violated. As a result of these suits it is declared the automobile industry in Texas has been hurt.

Syracuse Show Sells Many Cars

Prosperity in Central New York Section—30,000 Cars for 1916

SYRACUSE, N. Y., Feb. 26.—Some measure of the prosperity which is sweeping through Central New York was revealed at the show held in this city during the week ending to-day. Without exception, dealers and distributors expect to far exceed in 1916 their sales for 1915. Their optimism is based on the fact that during the year gone by manufacturing industries in the principal cities in this section has shown a consistent increase, that farmers are well out of debt, crops have been good, bank balances are heavy and there is promise of an early spring with early touring weather.

During 1915, the five counties which are contiguous to Syracuse, and from which Syracuse dealers draw their trade, absorbed 20,467 cars, according to figures supplied by the Secretary of State. These counties, with the number of cars registered are: Onandaga, 7270; Jefferson, 2943; Oswego, 1552; Cortland, 1368; Cayuga, 2326; Madison, 1106; Oneida, 3802. It is confidently expected that the average gain for 1916 will be between 25 and 30 per cent and that the territory should absorb nearly 30,000 cars. The combined population of these counties is 635,145, and of Syracuse itself, 149,000.

The show was the eighth annual affair and was staged by the Syracuse Automobile Dealers Association. Despite inclement weather during the latter part of the week, attendance was good, the average being nearly 5000 per day. The show was held in the State armory.

Portland Mfg. Co. Restarts

FLINT, MICH., Feb. 21—The Portland Mfg. Co., originally located in Portland, Mich., where it was burned out in May, 1915, has restarted in business here. The company which is capitalized at $12,000, will make besides electric and springless-gearless types of washers, a number of special accessories for the Chevrolet and Dort cars. The officers of the company are Arthur G. Lodewyck, president; Frank D. Lockwood, vice-president and Harry C. Shute, secretary-treasurer. Manufacturing quarters have been secured at 859 Patterson Street.

Cannot Revoke License

LANSING, MICH., Feb. 28—Attorney-General Fellows has ruled that the Secretary of State has no right or authority to revoke a chauffeur's automobile license for violations of the automobile law.

E.V.A.A. May Merge with N.E.L.A.

Work of Electric Vehicle Assn. To be Continued Under Auspices of National Body

New York City, Feb. 28—The Electric Vehicle Assn. of America has been invited by the National Electric Light Assn. to affiliate with it as a section, to be known as the Electric Vehicle Section, and that in the event that favorable action is taken by the E. V. A. A., its members will become members of the National Electric Light Assn., and the E. V. A. A. will be legally dissolved. A special meeting has been called to consider the invitation at the office of the association on March 10.

It is the present intention to discontinue any further meetings of the E. V. A. A. body, the members attending the regular monthly meetings of the N. E. L. A. The latter association expects to hold an exhibition May 22 to 26 at its convention in Chicago, and arrangements will probably be made for parking space either in Grant Park opposite the hotel, or some other nearby location for the display and demonstration of electric vehicles.

The Electric Vehicle Assn. of America was organized six years ago and now has a membership of 1150. The N. E. L. A. has a membership of 15,000 and has been in existence for forty years.

Bay State to Fight for Lower Gasoline Prices

Boston, Mass., Feb. 24—Massachusetts motorists have taken up the cudgels in the fight to reduce the price of gasoline in New England. At the request of the Bay State A. A. of Boston, Representative Thomas J. Giblin of the Massachusetts Legislature, has put in a resolution requesting that action be taken. He has asked the Legislature to pass the following:

> Resolved, That the motor industry has given such steady employment to so many thousands of our citizens, men and women; has increased the tax values of the State by many thousands; and has in other ways done so much to add to our prosperity, be it
>
> Resolved, That the Massachusetts Legislature send a resolution to its Senators and Representatives at Washington requesting them to take such action as will result in lowering the price of gasoline in the East, where its high price now jeopardizes the motor business of Massachusetts and gives Western States an unfair competitive advantage over our motor business firms and individuals.

50 Cents per Gallon

At the annual banquet of the Automobile Club of Springfield, Mass., which was attended by 750 members and friends, Thos. L. Hisgen, former independent party candidate for the presidency, who was the principal speaker, asserted that if action is not taken the price of gasoline will go to 50 cents in a year. Hisgen is an independent oil operator. He stated that the percentage of gasoline taken from crude is higher now than ever before; that figures based on facts prove that there is no oil shortage; that the trusts aim to stifle competition and maintain high prices after the war; that the company of which he is president refused an offer from an agent of the Allies to sell all the gasoline they could get at a profit of 4 cents per gallon; that he believes the committee appointed by the Bureau of Commerce to investigate gasoline prices is incompetent, and that the Bureau of Commerce refuses to divulge the names of the members.

Timken New Seamless Tube Plant Working Full Time

Canton, Ohio, Feb. 26—The new seamless steel tube plant of the Timken Roller Bearing Co., recently completed at an expenditure of about $500,000, is now in full operation, 24 hr. a day. It is an all-steel structure of the standard mill type. The piercing and rolling mills with their accessories are of the latest design, embodying a number of patented features which make for greatly improved hot finished tubes. The cold working department includes pickle house, annealing furnaces, pointers, draw benches, straighteners, cutting-off machines, and many other things which make the plant one of the most complete in the world.

Wardell Detroit Steel Products Sales Manager

Detroit, Mich., Feb. 26—H. F. Wardell has been appointed general sales manager of the Detroit Steel Products Co. in place of P. A. Smith, who resigned. Mr. Wardell was formerly office manager of the company. Previously he was with Albert Kahn, the architect, also with the United States Gypsum Co.

Hupp Makes Output Record

Detroit, Mich., Feb. 24—The biggest day of the winter season at the Hupp Motor Car Co., was on Thursday, Feb. 17, when 101 Hupmobiles were made. Although the plants here and in Jackson are working to capacity, the company is still over 700 orders behind the immediate demand.

Struggle for Race Selection

Elgin and Santa Monica Contend for Vanderbilt and Grand Prize

Chicago, Feb. 29.—The battle for the honor of promoting the Vanderbilt cup and grand prize road races for 1916 is on. At the annual meeting of the Elgin association, held last week, the directors and stockholders voted to apply for the sanctions for the two classics and directed Joseph Callendar a member of the contest board of the Chicago Automobile Club, to open negotiations immediately with the Motor Cups Holding Corporation, which controls the two trophies.

Santa Monica already is in the market for the two blue ribbon events.

According to the plans of the Elgin promoters, the Watch City meet will be of 8 days' duration this year, with 4 days of racing. The speed carnival will open Saturday, Aug. 12, with the Vanderbilt cup, and close the following Saturday, Aug. 19, with the grand prize. The C. A. C. cup event will be run on Tuesday, Aug. 15, and the Elgin National trophy contest on Thursday, Aug. 17.

At the annual meeting, which was one of the most enthusiastic sessions ever held by the association, no decision was reached regarding the distance of [illegible] four events or the piston displacement limit to be placed on the entries. These are matters that fall under the jurisdiction of the contest board of the Chicago Automobile Club.

The Elgin promoters have agreed to raise $10,000 of the $24,000 to be offered in purses by the sale of 1,000 season tickets at $10 apiece. Chicago race enthusiasts also have promised to sell the same number of tickets in advance.

The Elgin course has weathered the ravages of winter in splendid shape and very little work will have to be done on the roads to put them in condition for fast driving.

Business Good at Newark Show

Newark, N. J., Feb. 28—Newark's show ran true to 1916 form; it was the biggest and best it ever had, which is the experience that every other show-city has had this year. Paid admissions were double what they were a year ago despite an uninterrupted spell of intense cold alternated with driving rain.

The interest was greater, sales were more frequent, and there was a business-like air that was not so pronounced at previous shows.

The opening was Saturday, Feb. 19, and from the moment the doors were unlocked until the lights were turned out the building was a solid mass of enthusiasts. Many were car buyers but more probably were there out of curiosity, because the majority of the attendance on the opening night is complimentary.

The large attendance through the following week was no doubt due in large measure to the wholesale purchase of tickets by the various exhibitors for distribution among owners and prospects. The regular price of admission was 50 cents, but exhibitors could purchase blocks of 100 for $25. Many dealers bought 500 or more.

Interest in the show was stimulated by making every night except the last a special night. Opening night Gov. James F. Fielder was scheduled to make an address, and his failure to put in an appearance was not the fault of the management. Monday night the Mayor was there to act as host. Tuesday was Washington's birthday and a special musical program was arranged for the night. Wednesday was society, military and naval night—no extra admission was charged. Thursday was club night, the New Jersey Automobile and Motor Club acting as hosts to the 10,000 members of affiliated clubs of New Jersey. Friday was commercial vehicle night and the Motor Truck Club of New Jersey was host to the owners of motor trucks.

Chandler Profits $933,217

New York City, Feb. 24—The Chandler Motor Car Co., the old company, reports to the New York Stock exchange for the year ended Dec. 31, 1915, net profits of $933,217 as against $321,821 in 1914 and $42,232 in 1913. The new company up to Jan. 1, 1916 had $1,613,515 cash in the bank and on hand and a surplus of $173,450.

A comparison of the earnings of the old company for 1913, 1914 and 1915 is given in the following tabulation:

	1915	1914	1913
Gross profits ...	$1,507,360	$706,123	$154,461
Other income...	101,125	43,233	13,034
Total income.	$1,608,485	$749,406	$167,495
Expenses	641,733	428,585	123,363
Depreciation of plant	33,534	4,000	1,900
Net profits...	$933,217	$321,321	$42,232

The balance sheet of the Chandler Motor Car Co., new company, as of Jan. 1, 1916, follows:

Assets	
Real estate, buildings and equipment	$223,928
Good will and organization.......	5,000,000
Investments	43,240
Cash in banks and on hand.......	1,613,515
Accounts and notes receivable....	138,823
Inventories, at cost..............	622,644
Prepaid expenses	14,318
Total	$7,661,475
Liabilities	
Capital stock	$7,000,000
Accounts payable	410,152
Deposits from dealers on contracts	63,725
Reserve for taxes and contingencies	14,146
Surplus	173,450
Total	$7,661,475

Five Firms Have Credit Systems

Banks Support Schemes for Selling Cars on Installment Plan to Approved Buyers

Detroit, Mich., Feb. 28—Selling automobiles on installments or deferred payments has now become a standard part of the business of dealers selling at least five makes of automobiles. Doubtless other makers will be added to the list from time to time, but the five so far in line on the proposition are Overland, Studebaker, Chalmers, Maxwell and Paige, all large producers, and their announcements of arrangements on behalf of their dealers came out in about the order named. In every case the car maker has no financial interest in the credit company that buys the notes taken in by the dealers, but the maker has simply made the proper arrangements so that the dealer may do this class of business on a proper and logical basis.

In every case so far made public, an old and firm banking house is back of the arrangements, and while the plans differ considerably in their details, they follow about the same general idea of having one-half to one-third of the price of the car paid down and the balance in eight monthly payments. The banking firm then buys these notes from the dealer. Hence the dealer has a ready outlet for this paper and does not have to use his local credit for the purpose. Undoubtedly the installment idea will increase the sales of cars, for it opens up that field in which there are many who have enough to buy a car but cannot pay it all out at once.

Credit Houses Back Scheme

Following are the credit houses back of the time sales of the five cars mentioned:

Overland—Guaranty Securities Co., Toledo, Ohio.

Chalmers—Agricultural Credit Co., Chicago.

Studebaker—Commercial Investment Trust, New York and St. Louis.

Maxwell—American Commercial Co., Cleveland.

Paige—Bankers' Commercial Corporation, New York.

Up to a short time ago it was generally thought that automobiles could not be marketed successfully on the installment plan basis, because it was believed there was too much risk of damage and depreciation to the vehicle between the time of first payment and final payment. However, the new arrangements seem to overcome this difficulty.

However, with the wider use of cars by the general public and the need of an adequate method of doing such business so as to save the dealer from haphazard methods that might lose him much money or even wreck his business have decided some of the big producers of cars to make arrangements with banking interests to finance such transactions. Doubtless the great earnings of the automobile companies during the past year and the constantly increasing market for cars were big factors in bringing to the attention of big banking houses the matter of financing time sales, just as these factors have induced many moneyed interests to invest heavily in the expanding motor car factories themselves.

Arrangements Differ Slightly

Although the arrangements differ in details, the general scheme of these deferred payment plans is the same. Usually the dealer is required to take one-third or one-half of the list price of the car down, and the balance in eight monthly payments. The cost of insuring the car against fire, theft and transportation loss is added, as well as 6 per cent interest on the notes which the buyer gives. This is a cash sum that must be paid at the time the initial payment is made. Then the dealer indorses the notes and sends them to the banking house, which buys them from him less a brokerage charge that ranges from 2 to 3 per cent in most cases. In one or two instances the banking firm sends immediately the entire amount of the notes less brokerage, and in others an amount of $100 to $200 is withheld and the dealer given a deferred certificate for this. He can cash this certificate through the banking house when the customer has paid the last note, or if he wishes he can use it immediately by sending it to the car manufacturer, who will accept it on the purchase of more cars, less a discount of 5 per cent.

Buyer Specified

For this kind of business the plan laid down usually specifies the kind of person whom the dealer can sell on this deferred payment basis, and since he indorses the notes he is reasonably sure to satisfy himself that the party is able to pay for the car as agreed. Certain investigation procedure is given the dealer and usually all the necessary forms and notes are furnished him, so that the sales are made in a strictly uniform manner and in accordance with the rules the dealer is instructed to follow. He will, of course, follow them, as he wants the notes to be taken by the credit firm.

In most instances the plan does not interfere with the dealer's local banking arrangements, and there are no restrictions if he wishes to finance the installment sales through his local bank he is at liberty to do so. Usually the dealer needs all of his local credit for taking in the shipments of cars as they come from the factory, and the new scheme is a method whereby the dealer can take care of a much larger volume of credit sales than he would be able to do were he entirely dependent upon his local credit. Some of the car makers, however, do not favor the dealer financing any of their time sales through local banks.

Many will wonder why the banking firm will not remit them the entire face value of the notes less the brokerage, instead of paying all but about 10 per cent and giving a deferred certificate for that, paying it when the car is fully paid for. This is because it is held that the dealer must have some interest in the transaction after he has made the sale and taken the notes. Knowing that the balance of his money is dependent upon the payment of the last note, he will keep in touch with the customer and see that the latter keeps up his payments.

Pennsylvania Rubber Has $4,000,000 Business

CONSHOHOCKEN, PA., Feb. 24—The stockholders of the Pennsylvania Rubber Co., at the annual meeting elected the following officers for the ensuing year: Chairman of board, Herbert DuPuy; general manager, S. G. Lewis; secretary, G. W. Shively; and assistant treasurer, C. G. Morrill. The directors are Herbert DuPuy, H. W. DuPuy, C. M. DuPuy, S. C. Lewis, and G. W. Shively.

The company's report for the season of 1915, shows approximately a $4,000,000 business. Additions will be made to the factory facilities to take care of a production of not less than 2000 casings a day.

157 Chalmers Shipped Feb. 23

DETROIT, Feb. 23—All former shipping records were broken by the Chalmers Motor Co. to-day, when 157 Chalmers were shipped. The daily shipping schedule calls for 125 cars, but it is better than that most of the time.

Army Truck Bids Opened

Full Specifications Issued for Eight Trucks Needed by U. S. War Department

WASHINGTON, D. C., Feb. 26—Bids for supplying the U. S. Army with eight gasoline trucks will be opened in the office of the Chief of Ordnance, U. S. A., War Department, this city, on March 2. These trucks are to be four-wheel-driven with locking differentials whose normal capacity shall be 5000 lb., whose weight with body shall be about 6500 lb., whose speed shall be 15 m.p.h. maximum and whose power shall be 30 hp.

In the specifications of these vehicles, they are required to be capable of negotiating surfaces off the roads and to climb grades of as much as 15 per cent. Axles must be forgings and live axles should be of the floating type. There must be brakes in each wheel and also on the transmission, capable of holding the truck on a 25-per cent grade. Load distribution must be so that not less than 30 per cent or more than 45 per cent falls on the front wheels. The safety factor must permit 20 per cent overloads. The carbureter must be water-jacketed and fitted with a hot air connection. The tread must be 56 in. and the clearance 15 in., 8 in. under the brake drums.

Spark and throttle levers are required to be separate from the steering column. An accelerator, if used, must be to the right of the pedals. The radiator must be mounted on springs and preference will be given to the vertical tube type. It must be at the front and fitted with a drain. Circulation should be by pump, so arranged as not to interfere with thermo-syphoning. The engine should be supported on three points.

The engine is required to be under the hood, of four-cylinders, vertical and with inclosed valve mechanisms. The horsepower formula used is $HP. = .28N (b - 1.18) (s + b)$, in which N is the number of cylinders, b, the bore in inches and s the stroke in inches and must equal 30 by this formula. Towing hooks, after the Ordnance Department's specifications, spring-mounted, must be fitted fore and aft. A spur- or bevel-gear type of differential is required.

Shaft drive is required, worm drive being preferred. Universals may not be exposed. Thirty gallons of gasoline must be carried, 25 in a main tank and 5 in a reserve tank. A selective gearset is required with a total low reduction of from 30 to 40 to 1.

If magneto ignition is used, there must be a battery reserve. If an electric starting system is used, a separate storage battery shall be provided for ignition. Electric lighting is required, fed from a storage battery and in addition to the usual lamps, there must be a dash lamp and swinging searchlight on the dash. Torsion and propulsion through springs is considered undesirable. There must be three forward speeds and a governor set at 15 m.p.h.. A speedometer must be provided. No bright metal parts will be permitted. Four-wheel steering is preferred, but not insisted upon. Single tires, 36 by 6 are desired, mounted on cast steel wheels. Deliveries will be made f.o.b. train at Fort Sill, Okla.

Automobile Club Tests Tankii

NEW YORK CITY, Feb. 28—Results of a certified test on Tankii, a fuel preparation made by the Tankii Chemical Sales Co., Cleveland, Ohio, have just been announced by the Automobile Club of America, under whose auspices the test was made. The report of the technical committee indicates that no increase in miles per gallon resulted from its use. The test was made on the roads in Central Park, the car first being run with gasoline and then with the mixed fuel, the Tankii being in the form of white tablets. One tablet was added to each gallon of fuel.

A run with the mixed fuel showed 13.1 m.p.g., and with the plain gasoline under the same circumstances, 13.4 m.p.g.

Metal Prices Higher

NEW YORK CITY, Feb. 29—A contraction in the supplies of a few of the metals last week caused prices to soar. Tin advanced over $6 per 100 lb. in one day, reaching a new high mark of $50 per 100 lb. Lead reached $6.50 per 100 lb. yesterday, making a gain of 20 cents for the week. Aluminum kept up its rise, reaching 60 cents per lb. Bessemer steel went up $1.00 per ton to $35.

Pennsylvania crude oil went up to $2.40 a barrel on Tuesday. Reports reaching the oil refiners showed that during January there was a falling off of about 6000 barrels a day in normal runs and shipments, and the advance was made in the hope of making up this deficiency. Competent authorities, however, believe that the immense amount of crude oil now held in storage will not find the market until the price has reached $2.50 a barrel.

Crude rubber prices were a little higher with a steady market and a fair demand. Manufacturers did not show much disposition to anticipate to any extent, but the demand for moderate lots was on a fair scale.

Gasoline prices remained unchanged, with higher prices, however, expected. A number of curb brokers in Wall Street are hedging on gasoline. They are buying some oil stocks to cover any rise in gasoline. If gasoline goes up, they figure, oil stocks would also go up, and the profits would reimburse them for the high prices of gasoline. If gasoline went down, on the other hand, they figured they would take their compensation by buying cheaper gasoline, even though their oil stocks dropped a little.

Indianapolis Plant Sold

INDIANAPOLIS, IND., Feb. 24—The American Motor Realty Co., owner of the site and plant formerly occupied by the American Motors Co., at South Meridan Street and the right-of-way of the Indianapolis Union Railway Co., has sold the property for $70,000 to the Indianapolis Cordage and Implement Co.

Jeffery Cuts Hours—Raises Wages

KENOSHA, WIS., Feb. 24—The Thomas B. Jeffery Co., this city, has increased the wages of 2000 employees 10 per cent and reduced the working hours to fifty a week for day work and fifty-five for night work.

Maxwell Man in Orient

DETROIT, MICH., Feb. 24—Walter T. Langwell, of the sales department of the Maxwell Motor Co., sails for Japan and China, April 22, and will make an investigation of the automobile business in the Orient and the possibilities of further extending the Maxwell export trade in that part of the world.

Security Prices Lower

General Reduction Sets in with Little Activity—New Stocks Issued

NEW YORK CITY, Feb. 28.—Securities prices on Saturday were much lower, failing to hold their advantage of the previous week. In fact, a few of the leading stocks on the New York Exchange have gone under their low marks for 1916. Maxwell common at the present time is a little under its lowest mark this year, which was 63½. The first preferred is now quoting at the lowest price this year, that of 85. The second preferred at 48 is ½ point under its low mark for the year. Studebaker at 140 on Saturday was 1⅞ points below its former low mark while its preferred at 109 was just 1 point lower. General Motors and Willys-Overland have managed to quote above their lowest marks. General Motors, common, especially, is considerably ahead of its 1916 rock bottom price of 415 made on Jan. 7. Its present price is around 476. Its highest quotation was 495, made on Jan. 3. The highest point reached by this stock was 558 in 1915, having risen from 82 the same year. Willys-Overland, common, though considerably under its highest mark made this year, is at the present time about 10 points above the rock bottom price of 199¼. Its preferred has been very steady this year, there being very little difference between its high and low marks.

With the exception of a 5-point rise in Firestone common, the rest of the tire issues last week were lower. Miller Rubber common featured the decline with a 50-point drop. This stock has been subject to large fluctuations. U. S. Rubber common went down 1¼ points to 50½. The new Kelly-Springfield common also showed a decline of 1 point. This company has made a formal application for the listing of its shares on the New York Exchange. It is understood that trading in the issue on the big board will start March 9. In accordance with the provisions of the certificate of incorporation there has been set aside in the special surplus account $75,246, which will be expended in purchasing for retirement and cancellation the 6 per cent preferred stock. There will be $3,758,200 preferred and $5,877,200 common issued.

Another company to have its stock listed on the exchange is the Chandler Motor Car Co. This stock was taken from the curb market and placed on the Exchange board last Saturday. The company is listing $7,000,000 common.

There was a brisk demand for the new shares of the Continental Motor Co. on the Detroit Exchange. This stock is now $10 instead of $100. The bid on Saturday was 27 and it is next expected that a further rise will occur. On the last day the old stock was quoted, it went up to 505 bid, which was a gain of 55 points since Feb. 19.

Winton Co. Reverses Color System on Its Cars

CLEVELAND, OHIO, Feb. 26—The Winton Co. has reversed the usual procedure, where both light and dark colors are used on closed car bodies and is now putting the light shades above the seat line and the dark shades below. This plan of coloring is believed to make the cars look more cheerful, since the human vision has a tendency to take in the upper half of everything before the lower portion is noted.

Johnston President of Dealers' Assn.

NEW YORK CITY, Feb. 24—R. H. Johnston, manager of the New York branch of the White Co., was re-elected president of the Automobile Dealers' Assn. of New York. W. C. Poertner of the Poertner Motor Car Co. was elected vice-president, and C. M. Brown was re-elected secretary and treasurer.

Factory Miscellany

Oakes to Add—The Oakes Co., manufacturer of automobile parts, will enlarge its plant at Indianapolis, Ind.

Hamilton Carbureter to Add—The Hamilton Carbureter Co., 535 Queen Street, East Toronto, Ont., will build an addition to its factory at Toronto.

Ford Plant in Pocatello—The Ford Automobile Co., Detroit, Mich., it is stated, is contemplating the construction of an assembling plant at Pocatello, Idaho.

Carhart to Build—The Carhart Motor Co., 218 West First Street, Oklahoma, Okla., contemplates the construction of a plant at an estimated cost of $50,000.

Glidden Varnish to Add—The Glidden Varnish Co. will erect a $20,000 steel, four-story manufacturing and storage building at 11,020 Madison Avenue, Cleveland, Ohio.

Hamilton Watch to Make Speedometers—The Hamilton Watch Co., Lancaster, Pa., will construct an addition to its plant for the manufacture of speedometers. C. F. Miller is president.

Canton Automobile Co. to Add—The Canton Motor Car Co., Canton, Ohio, has placed contracts for the erection of a new plant. It will be a two-story brick and steel structure, 66 by 200 ft.

Steel Products to Add—The Steel Products Co. has purchased a tract of land adjoining its plant at 2206 Clarkwood Road, Cleveland, Ohio. The land will be used for an addition.

North American Co. Gets Foreign Order—The North American Motor Co., Pottstown, Pa., has made an initial shipment of its motor trucks to Manchester, England. This company has been recently established.

Prudden to Add—Plans have been prepared for the construction of a two-story, 70 by 540-ft. addition to the plant of W. K. Prudden & Co., manufacturer of automobile wheels at Lansing, Mich.

Belknap to Enlarge—Belknap Wagon Co. will practically double its plant on Front Avenue, Grand Rapids, Mich. The company makes automobile bodies especially for delivery purposes. It now has orders on the books for more than 250 special bodies.

Auto Devices Move—The Auto Devices Co., manufacturer of Pamco shock absorbers and several other automobile specialties, has removed from 3027 Locust Street to a larger building at 3214 Locust Street, St. Louis, Mo., and with enlarged manufacturing facilities will largely increase its output.

Bettendorf Trailer Co. Formed—The Bettendorf Trailer Co., Bettendorf, Iowa, has been incorporated with a capital of $100,000. The company has been manufacturing automobile trailers at Bettendorf for several months, and in the spring will erect a shop building, 300 by 300 ft. J. W. Bettendorf is president.

R & R Shock Absorber Adds—The R & R Shock Absorber Co., Elgin, Ill., has been compelled to increase the force of employees by twenty-five men to take care of an order for 25,000 sets of its product of 100,000 single absorbers. As soon as the material can be secured the company can turn out 2500 sets per week. An addition to the plant is contemplated.

First Rock Island Tractor—The first tractor completed since the Heider Company of Carroll, Iowa, consolidated with the Rock Island Plow Co., Rock Island, Ill., was turned out this week. For several years the Rock Island company has been marketing the Heider product, and when the demand became so great that additional facilities were required it was decided to consolidate, shipping facilities being improved by the change, together with many other advantages. It is hoped to turn out several thousand of the machines this year.

The Week in the Industry

Harris Gray & Davis Sales Manager—R. W. Harris has recently been appointed sales manager of Gray & Davis, Inc., Boston, Mass. Mr. Harris was formerly in charge of the Ford system department of the company.

Stone Makes Remy Change—G. B. Stone has been placed in charge of the Ohio-Indiana territory of the Remy Electric Co., Anderson, Ind. For a number of years Mr. Stone has been a member of the engineering department of the Remy company, doing specialized sales work in connection with engineering.

Farrington Joins Gibson Co.—Richard Farrington has been appointed assistant to H. R. Williams, manager of sales of the Gibson Co., Indianapolis, and will have charge of advertising. Mr. Farrington comes to his new position well equipped, as in addition to having been editor of the Automoble Department of the *Indianapolis Star* for sometime past, he was previously connected with an advertising agency, and also with newspapers in other cities.

Dealers

Ahlberg Opens Atlanta Branch—The Ahlberg Bearing Co. has opened a branch in Atlanta, Ga., at 323 Peachtree Street. This branch will be in charge of H. A. Fisher.

Cleveland Co. Builds—The Hudson-Stuyvesant Motor Co., Cleveland, Ohio, is building a $55,000 salesroom and service station. The building is on automobile row on Euclid Avenue and Twenty-first Street. The building, 50 ft. wide by 179 ft. deep, serves two purposes. The front section, 51 ft. deep, is an artistic commercial building, four stories high, of strictly fireproof construction.

Louisville Items—The Louisville Automobile Exchange, 544 South Third Street, agents for the Mitchell, Hollier and Partin-Palmer, have been appointed Chevrolet distributor in this territory.

The Standard Auto Co., 212 East Broadway, Louisville, agent for the Cole and Reo, is the new distributor for the Paige in this vicinity.

G. M. Cheschier of this city, who for two years has been Southern district manager of the Waverly Electric Co., with headquarters at Washington, D. C., has resigned to become district manager of Northwestern territory for the Milburn Wagon Co., Toledo, Ohio. He will make Minneapolis his new headquarters. For several years he was connected with the Southern Motors Co., Louisville.

Motor Men in New Roles

Collins Resigns—B. J. Collins, sales manager of the American Top Co., Jackson, Mich., has resigned.

Ryan Leaves Hupp—John Ryan, traveling representative of the Hupp Motor Car Co., Detroit, has resigned.

Pietsch Packard Mgr.—F. H. Pietsch has been appointed manager of the truck department of the Packard Motor Car Co., Chicago, Ill.

Suhr Promoted—F. W. Suhr has been appointed manager of the New York City motor tire department of the Firestone and Rubber Co.

Durie with Chase Truck—C. A. Durie has been made factory production manager by the Chase Motor Truck Co., Syracuse, N. Y. He succeeds J. E. Gramlich.

Kromer Transferred to Atlanta—P. W. Kromer has been transferred to the Atlanta, Ga., office of the Prest-O-Lite Co., Indianapolis, Ind. He was formerly with the Buffalo office.

Replogle Marathon Middle West Mgr.—H. H. Replogle is Middle West division manager of the Marathon Tire & Rubber Co., Cuyahoga Falls, Ohio. His headquarters are in Omaha, Neb.

Moore Cleveland Velie Sales Mgr.—R. L. Moore, who has for a number of years been intimately connected with the motor car business in Cleveland, Ohio, has become sales manager of the Cleveland Velie Co.

Kerr Joins Overland Forces—Melvin Kerr, formerly assistant branch manager of the King Motor Car Co., New York City, has been appointed western New York representative of the Willys-Overland Co. His headquarters will be in Rochester.

Redman Joins Chicago Michelin—J. E. Redman has been made assistant sales manager of the Chicago territory by the Michelin Tire Co., Milltown, N. J. R. B. Tracy, who was appointed factory representative recently, will continue to supervise the Middle West branches of the company.

Langmaid Resigns—Chase Langmaid, manager of the New England branch of the Federal Tire Co. for some years, resigned last week to become sales manager of the Needham Tire Co. He is succeeded by W. H. Piggott, who was sent on from the factory at Milwaukee. H. L. Diechert has been sent on also as New England traveling representative.

Crumley Detroiter Ssles Representative—A. A. Crumley has been appointed traveling sales representative of the Detroiter Motor Car Co., located in Detroit, Mich.

Ross Joins Dodge—Frank Ross, for the past five years superintendent of the Cleveland Foundry Co., Cleveland, Ohio, has accepted the position of superintendent of the compressed steel division of the Dodge Bros. factory located at Detroit.

Richards Goes to Pittsburgh—G. A. Richards, who has been manager of the Columbus branch of the Firestone Tire & Rubber Co., for three years, has been promoted to manager of the Pittsburgh branch of the company.

Hanson Joins Service Truck—A. B. Hanson, formerly manager of the service department of the Chalmers Motor Co., Detroit, has become general manager of the Service Motor Truck Co., Wabash, Ind.

Wellman Olds Advertising Manager—Fred Wellman has been appointed advertising manager of the Olds Motor Works, Lansing, Mich. He was formerly confidential assistant and advertising counsel to Carl G. Fisher in the Indianapolis and other enterprises. C. V. McGuire, former advertising manager of the Olds, has joined the Cheltenham Advertising Agency.

Dealers

New Dayton Rubber Dealers—The Alling Rubber Co., Albany, N. Y., and the Dayton Tire Co., Boston, Mass., have been appointed dealers for the tires of the Dayton Rubber Mfg. Co., Dayton, Ohio.

Cleveland Items—The Ris Motor Co., Cleveland, has taken on the Kissel-Kar in addition to the Dort, which was its original line.

W. J. Newcomb, Cleveland, Ohio, has purchased the business and stock of the Windermere-Euclid Garage Co. and taken over the lease of the building at 13,560 Euclid Avenue. Mr. Newcomb was formerly connected with the Baker-R & L Co., but will now devote his entire time to the new business.

The Coate Motor Car Co., Cleveland, distributor of the Paige and Pullman, is remodeling and enlarging its salesroom. A service station has been established at Euclid Avenue and East 66th Street, in order to give more room for the sales department.

Columbus Items—The Capital Motor Car Co., 168 North Fourth Street, Columbus, has decided to move to South Fourth Street, where a two-story garage and sales rooms will be erected by the concern. The new structure will be erected during the summer.

The Winders Motor Sales Co., Columbus and central Ohio representatives of the Chevrolet, Velie and Monroe, has decided to erect a modern sales room on East Long Street, near Fourth Street, which will cost approximately $25,000.

Wis. News Items—O. F. Fischedick, who, with J. D. Babcock established the first exclusive motor supply and accessory store in Milwaukee by organizing the Auto Supply Co. in 1910, has disposed of his interest to Mr. Babcock, who becomes president and general manager. Mr. Fischedick will engage in another department of the industry. The Auto Supply Co.'s main store is located at 134-136 Second Street, Milwaukee.

The Diener-Nelson Co., Milwaukee, State distributor of the Haynes and Grant, has moved from 809 Grand Avenue to new and larger quarters at 188-192 Eighth Street, Milwaukee.

The American Tire & Rubber Co., 252 Fifth Street, Milwaukee, has been appointed State distributer of Batavia tires.

The Jeffery Motor Service Co., Fond du Lac, has leased the entire first and part of the second floor of the Longdin-Bruegger Block and is converting it into a modern garage and service station. It will be ready May 1.

E. A. Glab and J. J. Glab of Milwaukee have organized the Pathfinder Sales Co., to act as distributer of the Pathfinder in Wisconsin and upper Michigan. Headquarters have been established at 163-165 Eleventh Street, Milwaukee.

The Motor Car Sales Co. of Milwaukee has been organized to act as Wisconsin distributer of Marmon cars. Temporary headquarters have been established at 136 Mason Street, pending the completion of the company's own garage, which will be located in the downtown district. The concern also is Milwaukee agent for the Oakland line. F. P. Lynch and P. B. Hustis are in charge of sales and George Kerner manager of the service department.

The Universal Auto Supply Co., organized recently as a corporation in Milwaukee, has opened a store and service station at 468 Jefferson Street.

The Anderson Electric Car Co., Detroit, Mich., has established a direct factory branch at Milwaukee, in charge of J. A. Crandall. Headquarters have been opened at 604 Downer Avenue. Mr. Crandall was formerly associated with the Detroit electric branch in Chicago.

San Francisco News Items—The Latham Davis Co., San Francisco, has been appointed Northern California agent of the Case Car, which it will handle in addition to its Stutz and Fiat lines.

M. M. Hartmann of the Hartmann Motor Sales Co., who was recently appointed Pacific Coast distributor of the Lozier car has named William Sealey as manager of his San Francisco office.

G. K. Arnold and J. H. Stelling, formerly of New York, have been appointed Pacific Coast agents of the Simplex-Crane. Mr. Arnold was formerly connected with the Packard and S. G. V. agencies in New York City and Stelling was identified with the De Dion Bouton Co. In addition to the Simplex-Crane car the new firm will handle the Lancia in this territory.

With the arrival in San Francisco of Eli White, chief construction engineer of the Hood Co. of Detroit, last week the first step in the building of the million-dollar Chevrolet assembling plant in Oakland was started. The new plant will furnish close to 150,000 ft. of floorspace and will be so built as to allow the putting together of 8000 Chevrolet cars a year. It is anticipated the factory will be in working order by July 1. The location of the plant is right on the Lincoln Highway in Oakland.

Many Agencies Being Closed at Boston—The activity in Boston motor circles is evident from the way agencies are being placed without waiting for the motor show. J. W. Bowman has closed up to represent the Daniels Eight. He also has the Velie. W. B. Dorr and A. J. Griffen have formed the Dorr-Griffen Co. to handle the Crow-Elkart, with salesrooms on Commonwealth Avenue. F. L. Brown, New England distributor of the Apperson, has formed a new company to handle the line at retail in Boston, with R. W. Shank and J. G. MacMurray, two former Buick salesmen, as partners and they have leased the old Dodge Bros. quarters on Boylston Street. B. W. Krogman and E. J. Sullivan have formed the S. J. R. Motor Sales Co. to handle the new S. J. R. Boulevard roadster being made at Boston, they having taken Maine, New Hampshire and Vermont. G. D. Rathburn of Malden has taken the agency for the Elcar, and he will open salesrooms in Boston shortly. And A. C. White, Jr., resigned recently to take on the Vim truck for New England. W. L. Burgess, sales manager for the Dorris, was in Boston last week and he expects to close an agency shortly and J. W. Moon has plans developing to have his car represented. V. A. Charles, New England distributor for the Briscoe, has given up the retail sales, and it is to be taken over by the Porter Motor Sales Co., handling the Pathfinder.

Gardner Machine to Add—The Gardner Machine Co., Beloit, Wis., manufacturing disc grinders widely used in automobile factories, garages and other shops, has made plans for an addition of the same size as the one now being completed. Both buildings will be 60 by 60 ft. The company's business has increased enormously in the last 8 months, making enlargement imperative. The establishment of many garages and repairshops throughout the country has created a heavy demand for small grinders. The C. H. Besly Co., Chicago, which has works at Beloit, is also enlarging the new shop recently completed.

Tower Truck Co. Formed—The R. J. Tower Motor Truck Co. has been formed at Greenville, Mich., with a capital stock of $50,000. A truck with several new features and a novel system of traction will be manufactured. R. J. Tower is president of the company, Francis Tower, vice-president, and C. V. Coats, secretary and treasurer. Besides the officers T. B. Winter and H. L. Baker are stockholders. Factory buildings have been secured and the manufacture of trucks will start at once.

Parish & Bingham to Add—The Parish & Bingham Co., Cleveland, Ohio, has secured a permit to erect a fireproof addition to its factory building at 10,601 West Madison Avenue. The building will be 900 ft. by 100 ft., with a height varying from 20 to 30 ft. At the same time it asked permission to build an addition to its boiler room. The two will cost about $130,000. Several other modern buildings have been planned by the company.

Kissel to Build Again—Plans for the proposed new factory building to be erected by the Kissel Motor Car Co., Hartford, Wis., on the 17-acre tract recently acquired for future extensions, are being drawn. It is said that work will be undertaken before June 1. The company is completing a large shop addition at this time.

Highway Tire Protectors' Separate Plant—John J. Bukolt, who has been manufacturing Highway tire protectors in connection with his other business, the Automatic Cradle Mfg. Co., at Stevens Point, Wis., will separate the two industries. A $100,000 corporation will be formed to take over the tire appliance and accessory business, and a new fireproof factory affording 15,000 ft. of floorspace will be erected. The present combined works are employing nearly 200 men on two 10-hr. shifts, and more than $3,500 worth of new machinery and tools has been contracted for to relieve the high tension caused by the extraordinary demand.

Steel Clad Auto Bow Co. to Start—The Steel Clad Auto Bow Co., Holland, Mich., has been organized here, its capital stock being $50,000. H. R. Schnarr is president, Henry Winter secretary, and Dick Jellema vice-president and treasurer. The old Holland Mfg. Co.'s plant will be occupied by the new concern.

Patent No. 1165861

Hudson Super-Six

Wasted Power Now Reserve Power

THE Super-Six motor has identical size with the former Hudson Light Six.

But the former type, at its best, delivered about 42 horsepower. The Super-Six delivers 76 h.p.

No more power is created, no more fuel is consumed. All that added power—that extra 80 per cent—is power that was lost in friction. And that friction was due to vibration.

THE IDEA IS NEW

The Super-Six motor follows standard practice in all respects save one. But that one new feature, by eliminating vibration, gives us 70 per cent more efficiency.

The idea is new—a basic invention—as proved by the fact of our patent. It is also proved by performance. The Super-Six has broken all the stock car records.

It has outrivaled every former type — Sixes, Eights and Twelves.

And this new motor is a Hudson invention, controlled by Hudson patents. So it gives to the Hudson unquestioned supremacy.

Reason for 76 H. P.

In the light-weight Hudson this 76 horsepower means a vast reserve power.

It means effortless performance on any road or hill. It means quick acceleration, matchless flexibility.

It means economy, for the motor rarely runs at more than half its capacity.

It is not added power, remember. It is power that we save by saving vibration—power that was heretofore wasted.

LITTLE ENGINE WEAR

All this extra power—this 80 per cent—means that much lessened friction. Engine wear has been almost eliminated.

In our speedway tests a Super-Six stock motor was run for 1350 miles at speed exceeding 70 miles per hour. It was the hardest test a stock car ever stood. But not a part or bearing showed any discoverable wear.

The motor's endurance has been almost doubled by this Super-Six invention.

Take a ride in the Super-Six. Put it through its paces. Then you will realize that fine-car buyers are bound to demand this efficiency.

All Other Cars Outrivaled

At Sheepshead Bay, under A. A. A. supervision, a 7-passenger Super-Six stock car excelled all former stock cars in these tests.

100 miles in 80 min. 21.4 sec., averaging ***74.67 miles per hour***, with driver and passenger.

75.69 miles in one hour, with driver and passenger.

Standing start to 50 miles an hour in 16.2 sec.

During these tests the car was driven 1350 miles at top capacity, at speed exceeding 70 miles per hour without discoverable wear on any part.

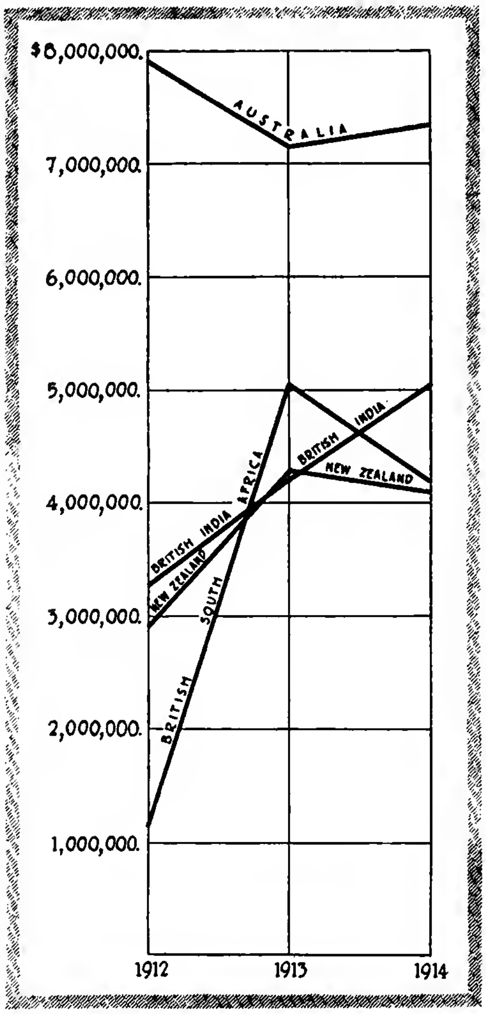
The British Empire Needs Vast Numbers of Cars and Trucks Which Can Come Only from America

By A. Ludlow Clayden



Automobile import trends in the British Empire

FOR the past several years American made cars and trucks have been exported in increasing numbers to the outlying parts of the British Empire. Australia, New Zealand, South Africa, India and the lesser portions of that vast territory, have looked to England for the major portion of their vehicles, but the eminent suitability of the American car to countries constituted much like America, has earned for it a growing popularity.

Canada is outside the argument, for Canada is a market which the American manufacturer enters without thinking about it; so in the following analysis of British Empire markets, Canada is left entirely out of the calculations.

The immediate conclusion, born of a close study of the import statistics of the major British colonies, is that Australia, New Zealand and South Africa, together with India, will want to buy $100,000,000 worth of automobiles during the next two years. These colonies are not feeling any pinch of war; on the contrary they are supplying many needs of the mother country and being paid for them in hard cash; the modern or reawakened patriotism of the Briton is a distinctly profitable thing to the Empire as a whole. Thus the colonies not merely want American cars, but have ample ready cash to pay for them.

It has been generally understood that many American manufacturers have been doing a good trade with British colonies these past twelve months, but it needs figures to show how great is the actual opportunity for immediate sales and future business.

Take Australia first, as being about the largest buyer of automobiles among the newer countries of the world. Unfortunately it is not possible to give statistics for 1915, as there has not yet been time for the compilation of the figures and their transmission to America, but sufficient is shown by study of the returns for previous years to indicate the trend of affairs. Taking the graph on this page, we see the automobile imports of the four major British colonies for 1912, 1913 and 1914 have shown a steady and substantial increase; moreover it shows that the American imports have risen very considerably in value.

However, it is not so much the value of the imports from the different countries that matters so much as the total values. Studying the curves of total importation, although we have only three points on each, it is yet self-evident that each of these four countries is absorbing automobiles at a rapidly increasing rate. It is safe to assume that the demand for cars in Australia, in New Zealand, in South Africa and in India is progressing in a normal way. None of these countries is pinched by war, and the extent to which taxation has risen is offset by the increase in the demand from Europe for their products.

Thus if we carry on the curves for another couple of years through 1915 and 1916 up into 1917 it is obvious at once that there will be a very large market indeed for cars and trucks and a very strong demand.

In 1914 the British colonies imported a total value of automobiles of roughly $30,000,000. Of this total the United States supplied only between $7,000,000 and $8,000,000. The balance of very well over $20,000,000 came mainly from England and France, with a fair amount from Italy, Belgium and Germany.

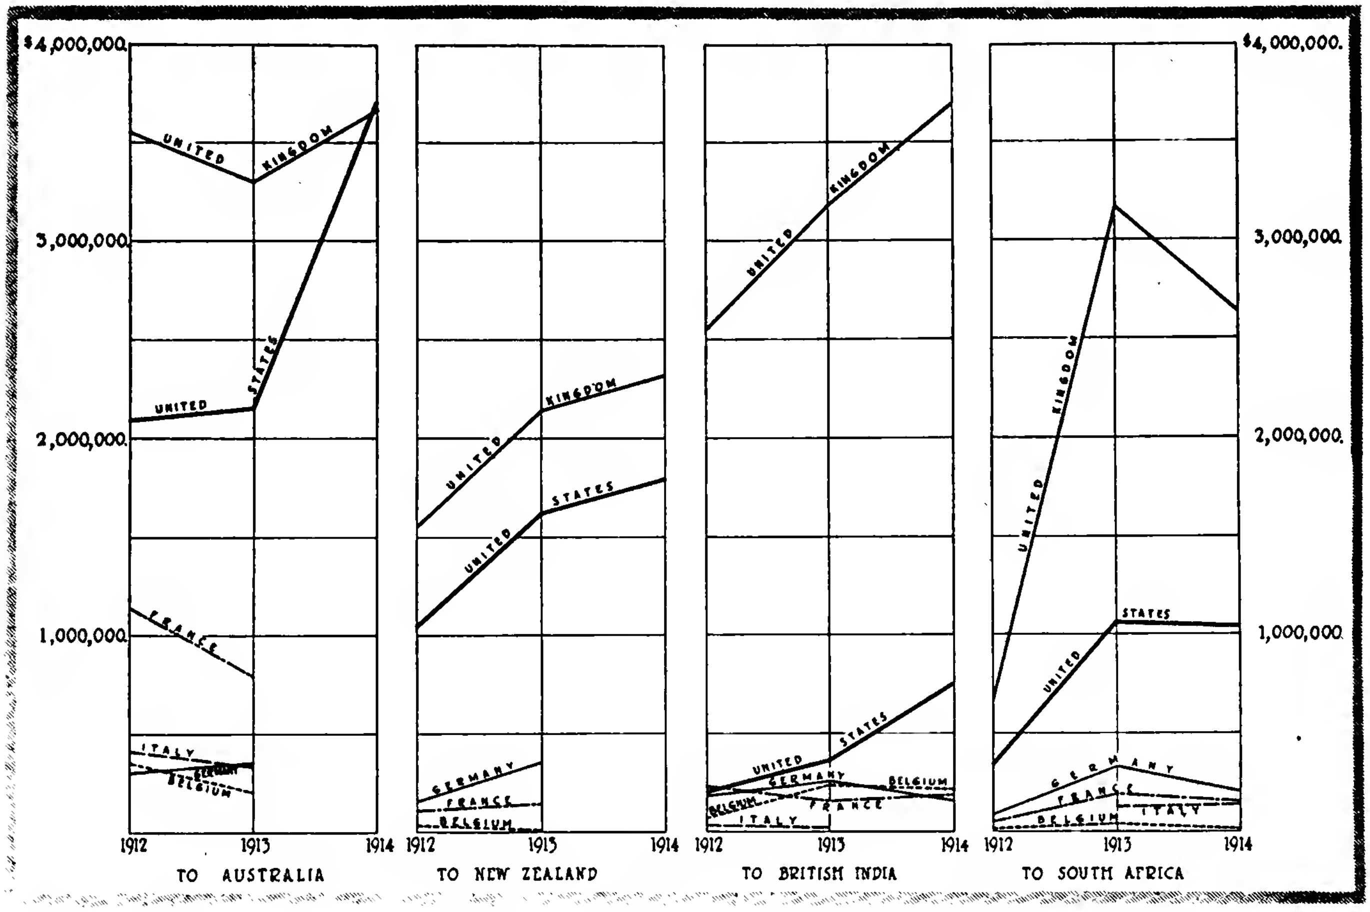
Exports of Motor Vehicles, Motor Cycles and Accessories —In American Dollars

	To Australia			To New Zealand		
From	1912	1913	1914	1912	1913	1914
United States	$2,088,225	$2,123,321	$3,695,595	$1,045,000	$1,620,000	$1,789,951
United Kingdom	3,545,268	3,308,956	3,663,600	1,560,000	2,145,000	2,325,900
Germany	332,142	366,645	....	157,000	355,000	....
Belgium	360,948	220,248	....	24,000	5,000	....
France	1,145,526	779,458	....	120,000	131,200	....
Italy	430,980	359,936	....	....	....	....
Total	$7,903,089	$7,158,564	$7,359,195	$2,906,000	$4,256,000	$4,115,851

	To British India			To South Africa (‡British)		
From	1912	1913	1914	1912	1913	1914
United States	$201,000	$365,500	$752,698	$348,300	$1,167,371	$1,045,000
United Kingdom	2,560,000	3,185,000	3,699,917	670,800	3,180,000	2,630,000
Germany	195,000	260,000	167,802	77,400	330,000	205,000
Belgium	79,500	240,000	220,959	12,900	35,027	9,510
France	220,500	165,000	195,181	51,600	195,300	154,500
Italy	25,100	13,500	....	....	121,000	139,932
Total	$3,281,100	$4,229,000	$5,036,559	$1,161,000	$5,028,698	$4,183,942

‡Figures are for year ending Dec. 31, 1914, which, because it includes 6 months of the war slump period, no doubt accounts for the decrease shown all down this one line. Note that U. S. exports show an increase to each country for 1914, except South Africa, which is not the case in regard to the exports from the other countries.

Curves Showing Trends in Importation from America, United Kingdom, France, Italy, Belgium and Germany from 1911 to 1914



Despite the war the British colonies are all in a state of fair prosperity. Every year for the past five the total imports to Australia, South Africa, New Zealand and India have increased with the exception of South Africa, which showed a slight drop in 1914. Probably this was because South Africa had some actual fighting to do in its own territory.

On the whole it is reasonable to assume that the upward trend has been maintained through 1915, judging by individual reports we have published. Assume the upward curve to be persisting and the four principal parts of the British Empire (excepting Canada) would have wanted about forty million dollars worth of automobiles in 1916. Of these, thirty millions would come from Europe in normal times. At present Europe cannot supply a single vehicle.

$30,000,000 This Year

This means that, if they can seize the chance offered, American automobile manufacturers have a market for a minimum of $30,000,000 worth of goods this year in four countries, all easily reached from our ports without going near any war zone.

Nor is it for this year only, for, if the war should end to-morrow, it will be two good years and more before the factories of Europe are again ready for exportation in any substantial quantity.

Then again, in 1913 the total value of German exports to the four parts of the British Empire which we are considering was $1,311,645, and the total figures for the first half of 1914 show that there would have been a substantial increase if the war had not intervened. Germany will have to wait many years before these markets are open again. Italy is not an important factor, and the French imports show a general decline. This means that Great Britain and America are left alone, almost, to struggle for the rich markets of the Empire.

America's Help Essential

Nor is it really a question of struggling. Great Britain, unless her methods of manufacture undergo a vast change, will be totally unable to supply the needs of the overseas parts of her dominions. The demand for passenger cars and trucks in England itself to-day keeps the importers busy, and, when the war is over and the British factories are once more producing automobiles, the domestic demand will easily absorb all the output. No doubt the importation of American cars into England will receive a check at the end of the war, as the feeling is very strong that Great Britain ought to do everything to keep her money within her own boundaries, but the more of her own output that England takes, the less will she have for export purposes.

This being so the American manufacturer is the only one left who can possibly satisfy the needs of Australia, South Africa, New Zealand and India, for the next five years or more, and probably longer.

The possibilities of the British Empire as an automobile market are staggering in their immensity. The enormous areas and the immense population provide an ever-increasing outlet for every possible sort of machinery.

Taking the Indian Empire alone, its 2,000,000 square miles with over 300,000,000 inhabitants represents an area of fairly dense population and with far from good means of transportation. Certainly, of that 300,000,000 the vast majority is semi-savage, but fully civilized or half civilized, there are many millions who spend their time in going to and fro just as in more fully developed Western lands. For the truck and omnibus as well as for the passenger car India offers a field almost as big as the U. S. A., which will develop slowly year by year for a century ahead.

Unexploited Fields

In Australia, New Zealand and South Africa, much of the land is yet unbroken, is trackless and railroadless, but the kerosene tractor, and the automobile plow, are wanted to convert the wild land for cultivation; and then the motor truck will come to haul the produce to rail or river head. Countries developed a century ago were essentially railroad countries, but those which are just being opened up to-day will be automobile countries first, because a practicable road for automobiles is a far cheaper thing to build than a rail track.

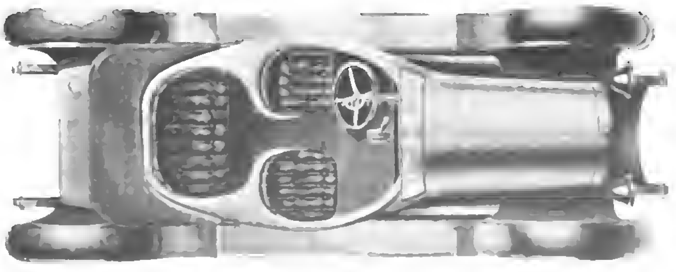
There is no river in the world where the chug-chug of the motor boat cannot be heard, there are few cities where the motor car is not being used in the great work of expanding and extending civilization. Great roads cut through the forests of Africa may be a vision of the future, but it is a less far distant future than most men would imagine.

Overland Adds Clover Leaf Body Type

THE six-cylinder Overland, model 86, can now be obtained in limited quantities with a clover leaf body to seat three or four passengers. The car will sell for $1,290 f.o.b. New York, and the chassis is identical with the standard six Overland except that the gasoline tank is at the rear, on the deck and with the filling cap at the side.

The new body will be finished in four colors, gray, green, red or blue, the wheels being a suitable contrasting tint, except for the vermillion car, which has wheels in the same paint as the rest of the body.

The Ohio Electric Car Co., Toledo, Ohio, are the manufacturers of the body, and the procedure for buying one of these cars is to order the chassis from the Overland Co., with instructions to deliver to the Ohio Electric Car Co., who will receive separate payment from the dealer ordering the car.



Overland Model 86 size cylinder chassis with clover leaf body equipment

The Sizes of Motors for Trucks and Outline of British Practice in This Field

An Exposition Covering Especially Those Features in the Design of Automobile Motors Which Should Vary According to the Different Conditions of Vehicle Service

By W. D. Williamson

Extracted from a paper entitled "Engines for Petrol Commercial Vehicles" presented by Mr. Williamson to the British Institution of Automobile Engineers. In the review of practice, forming a part of this paper, only motors for vehicles having a useful load capacity of two tons and upwards are considered, so as to exclude design which is artificially influenced by taxation based upon the bore of cylinders.

Part 1—Factors Governing the Sizes of Motors

THE designer of pleasure cars, after doing all he can to obtain the maximum of torque from a given cylinder, devotes his energies to the pursuit of "revolutions." To him, and to the aeronautical engineer, horsepower for weight is a serious consideration. In motors for commercial vehicles, on the other hand, the design is unhampered in this respect, in so far as additional weight is not of great moment, except in reciprocating parts, if it serves a useful purpose. Utility and manufacturing cost are the guiding considerations, and the designer can set out to produce a motor which will give the best possible results, in the hands of the average user, under the conditions for which it is intended.

Requirements in General

The user demands a vehicle with high fuel economy per ton-mile and reasonable speed. The motor must be robust, to insure against breakdowns, and the parts must be accessible, to facilitate adjustments and replacements. Here bore and weight are not involved. The user is often favorably impressed if the cylinder bore is, for example, ⅛ in. larger than in a competing vehicle.

Silence of operation has not so far been an outstanding feature or indispensable for the success of commercial vehicles. Motor noises were drowned in the general uproar. But live axles, inclosed chains and quiet gear boxes are bringing about a change. Motor buses and char-a-bancs set the fashion. The quietness of one portion of the chassis throws the noise from another into prominence. In one after another the noise is remedied, and finally the demand for a quiet motor, too, makes itself heard. To-day, on fair roads, high-class lorries operate with a lack of fussiness undreamed of a few years ago.

The motor must be produced at a competitive price. This requirement is related to those already mentioned, in so far as a low production cost for the motor enables a manufacturer to meet competition by putting all or a part of what he saves on the motor into improvements or workmanship that will tend to maintain his prestige.

The design must be adaptable to variations in size. As few British builders of commercial vehicles confine themselves exclusively to one type or size of chassis but usually cover load capacities from two to five tons and sometimes one or two sizes for passenger work, they have to provide a suitable range of motors, and from a manufacturing point of view it is highly desirable to obtain this range or series of motors with the fewest possible changes. The engines may be grouped so that one size is made suitable for two or three different types of vehicles, and provision can be made in some cases for larger cylinders and pistons to be used in conjunction with standard crankcases where additional power is required. The methods for attaching the motors to the frame can be standardized, so that it becomes possible to fit, for example, either a 30-hp. or a 40-hp. motor in the same frame without too many alterations. A little forethought in this direction may mean advantages both to himself and to the user.

Determining the Size of Motor

Motor speed and road speed are the most important factors for determining what the size of the motor should be. The ratio between them must be decided, and, in order to do so, the most economical motor speed must be discovered, as well as the average road speed giving the best vehicle results.

In ordinary delivery work for loads of two to four tons, a very satisfactory maximum speed is 15 m.p.h. For loads of four to five tons, this should be reduced to 10 or 12 m.p.h. For passenger vehicles greater speed is frequently demanded, and their hill-climbing speed must be better than that of a lorry or van, so that their motors must be correspondingly larger, but for commercial vehicles in general the figures mentioned may be taken as normal.

The best motor speed for these vehicle speeds depends largely on the type of engine used. Hence the type of the engine must be considered first. Broadly, it is found that the high-speed and high-compression motor so largely used for pleasure cars does not suit. Such a motor in a pleasure car is rarely required to run at low speeds with full throttle opening, and then usually only for short periods. In other words, in its average use the volumetric efficiency is low, its compression is reduced by throttle restriction and its rate of revolution is considerably below the maximum. Motors of this type are also apt to require more attention to minor points than the commercial vehicle motor obtains. While it is desirable to fit an engine no larger than the work requires, the weight consideration, which is mostly responsible for the pleasure car type of motor, should give way to those related to length of life and reliability.

One of the principal points in determining the most suitable type is to ascertain the motor speed at which the best results are obtained for the gasoline consumed. And, with the vehicle speed decided upon, this means the motor speed which will drive the vehicle at the selected road speed with the minimum of fuel cost, unless other factors cause a modification in this. In other words, the desirable speed for any particular motor must be determined through comparison and consideration of its torque and consumption curves.

Characteristic Torque Curves

The diagram of curves taken from a Dorman motor and shown in Fig. 1 illustrates the points to be considered. In examining this torque curve it is seen that from the lowest speed at which regular torque is obtained—about 300 r.p.m.—there is a rise showing increased load on the piston. The effective torque of the motor depends upon volumetric efficiency, cooling, carburetion, internal mechanical loss and on the relative gains and losses due to these governing factors at various speeds.

The volumetric efficiency should be greatest at the lowest speed at which the engine will run steadily, as under such conditions the cylinder should receive a full charge of mixture. At this speed, however, the cooling effect is most pronounced. The working temperature of the whole engine is lower; the heat losses during the cycle are considerably greater than at high speeds, and the thermal efficiency of the engine suffers. Carburetion at this speed with the usual carbureter setting would probably not be as perfect as at higher speeds.

Mechanical loss per stroke or per cycle where lubrication is thorough, might be expected to decrease with increased speed, if the actual loss due to friction alone is taken into account. In addition to this, however, the engine is called upon to overcome the valve spring pressure and valve inertia, and to drive the fan, water pump and magneto. The loss due to these increases more rapidly than the gain due to decreased friction, so that there is a probability of a greater total mechanical loss at high speeds.

It might be suggested that by suitable carbureter setting and by modification of the cooling arrangement the thermal losses at low speeds could be reduced, and the engine made to give an excellent torque at this speed. This is, no doubt, quite true, but the object is not to endeavor to alter the conditions to make the engine produce good results at any particular speed, but rather to find out at what speed the engine gives the best all round results for our purpose.

Tracing the torque curve through its rising speed the maximum is approached at about 700 r.p.m., and the curve remains fairly flat from there to 1000 revolutions, where it commences to fall.

Up to 700 r.p.m. the power of the engine per cycle is evidently increasing. The volumetric efficiency may be decreasing, the mechanical losses probably increasing, but these are evidently more than balanced by the increase in thermal efficiency and the more perfect mixing of the charge.

From 700 to 1100 r.p.m. the gains and losses are evidently almost balanced, as there is little variation in torque between those speeds, but as the speed increases, restrictions due to the valves and pipes begin to have their effect. Volumetric efficiency probably falls off and mechanical losses increase, and the net result is a decreased torque.

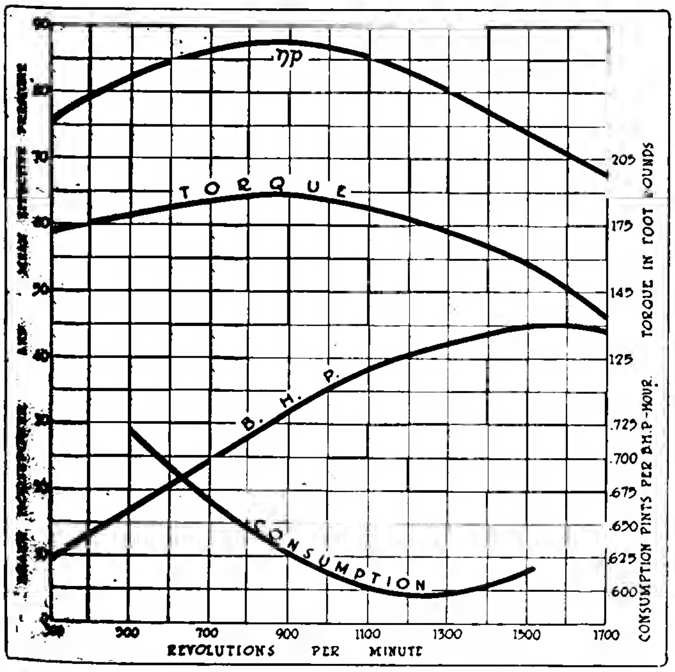


Fig. 1—Curves showing Torque and Consumption. 110 MM. × 140 MM. Dorman Engine

Consumption Curves

Considerations of torque alone would lead to the conclusion that unless the valve and pipe diameters are increased the engine is likely to give the best results if its range of revolutions is kept between 700 and 1100 r.p.m. Before any definite conclusion can be arrived at, however, it is necessary to go into the cost of this torque. The object in a commercial vehicle engine is to obtain torque for the least possible expenditure of gasoline, the ideal being attained when the range of maximum torque coincides with the speeds for minimum consumption—a result which is rarely obtained. While the consumption curve must depend on the carbureter setting for its actual value and relationship to the torque curve, it is generally found that the range of minimum consumption is at a higher rate of revolutions than that of maximum torque. When this range is confined to within 15 per cent of the best consumption, the curve shown would give from about 700 to 1300 r.p.m. as the correct range of speeds.

At 1300 r.p.m. the torque is falling, and although the torque per foot-pound is costing no more, since the consumption is at its best, yet the best range of mechanical efficiency is being departed from. If the maximum engine speed is taken at a point far down on the descent of the torque curve, the resulting torque is only equivalent to what might be obtained from a smaller engine at a lower speed. There appears to be no objection to allowing the maximum speed to be located some little distance down the curve, as on meeting increased tractive resistance the reduction in engine speed to come within the range of maximum torque would not be great. This maximum speed might then be taken at 1300 r.p.m.

An examination of the curves on these lines would lead to the conclusion that the maximum engine speed would be governed by the torque curve, and the minimum speed by the consumption curve.

If the left-hand end of the curves be considered, it is found that from 700 to 500 r.p.m. the torque value is moderately high, but the consumption curve shows that this torque is only obtained at a very expensive rate.

Take the case of a vehicle under load ascending a hill which eventually causes a change to a lower gear. As the tractive effort increases the engine speed falls from its maximum to a speed at which a higher torque value is obtained, and this continues until, with the driver's well-known persistence in hanging on to the top gear as long as possible, the engine speed has fallen back to below 700 r.p.m., and the engine is running outside its range of economical working.

High torque at this low speed end of the torque curve is therefore not an advantage unless it is accompanied by reasonable fuel efficiency.

Number of Cylinders

The four-cylinder engine appears to have become firmly established for commercial work, and can be taken as standard for the vehicles under consideration. The only heavy vehicles having engines of more than four cylinders are for fire engine or other special purposes.

Calculations for Engine Size

The usual ratio of engine to road speed in modern vehicles is for 1000 r.p.m. to correspond to about 15 m.p.h., but for any engine with curves corresponding to Fig. 1 there is a decided advantage in increasing the engine speed to 1300 r.p.m. Not only is the consumption improved, but the increased speed allows a decrease in engine size for any given weight of vehicle, with a corresponding lightening of transmission parts up to but not including the final drive. For the engine under consideration it is proposed to assume 1300 engine revolutions per minute for 15 m.p.h. The next step is to arrive at some formula to give the actual figures for engine sizes to meet particular requirements.

In the following method the author has aimed at obtaining a formula that is easy to handle rather than one which will give accuracy to a large number of decimal places.

The useful work obtained from the engine per minute is represented in foot-pounds by:

Mean effective brake pressure × area of cylinder in square inches × stroke in feet × number of working strokes.

Let V represent volume of one cylinder in cubic inches,
D the diameter of cylinder in inches,
S the stroke in inches, and
N the revolutions per minute.

and if r is taken as $\frac{\text{stroke}}{\text{bore}}$, then stroke $= r\,D$ and the useful work obtained per minute is:

$$\eta p \times \frac{\pi D^2}{4} \times \frac{r D}{12} \times 2N$$

(In which ηp represents, as usual, *M.E.P.* multiplied by the percentage of mechanical efficiency.)

or

$$\eta p \times \frac{\pi r D^3}{4} \times \frac{N}{6} \text{foot-pound}$$

but

$$\frac{\pi r D^3}{4} = \text{Volume of one cylinder,}$$

and therefore $\eta p \times \frac{N}{6} \times V =$ foot-pound per minute.

The Factor "Q"

The work this engine has to perform is to propel the vehicle against the internal friction of the vehicle itself, the external resistance due to the road and the wind pressure.

Let S represent the speed of vehicle in miles per hour.
W the gross weight of vehicle in tons.
R the total resistance on the level in pounds per ton.

Then the total foot-pound of work per minute required by the vehicle on the level is:

$$W \times R \times S \times \frac{5280}{60}$$

Hence, for an engine just large enough to drive any vehicle of gross weight W on a level road:

$$\eta p \times \frac{N}{6} \times V = W \times R \times S \times \frac{5280}{60}$$

Taking ηp at 80 lb. from Fig. 1, and R at 71.5 from Fig. 2, with 15 m.p.h. at 1300 r.p.m. we get:

$$80 \times \frac{1300}{6} \times V = W \times 71.5 \times 15 \times \frac{5280}{60}$$

or $$V = W \times \frac{71.5 \times 15 \times 1760 \times 3 \times 6}{60 \times 80 \times 1300}$$

or $V = 5.5\ W$ approximately

That is to say, the cubic capacity of one cylinder of the engine is found by multiplying the gross weight of the vehicle in tons by 5.5. This factor the author has called "Q." In dealing with "Q," it must be remembered that the factor assumes a definite ratio between engine and road speed—in this case 1300 r.p.m. and 15 m.p.h.

An engine designed with a "Q" of 5.5 would not be a commercial success. As long as the vehicle remained on a level road and had a total resistance of 71.5 lb. per ton the engine would be equal to the work required, and would be doing that work under most economical conditions. The drawback is that it has practically no reserve for hill climbing.

Curve 1, on Fig. 2, shows the engine torque taken from Fig. 1, and is plotted to correspond with the figures for road resistance. This shows the engine torque and road resistance cutting each other at 15 m.p.h. On an increasing gradient, as the engine speed falls the torque increases to a maximum at about 1000 r.p.m. and the road resistance decreases. The ability of this vehicle to climb is represented by the distance between the Curve R and Curve No. 1, Fig. 2, but at its maximum is less than 30 lb. per ton, which is the increase in resistance due to a gradient of only 1 in 74.

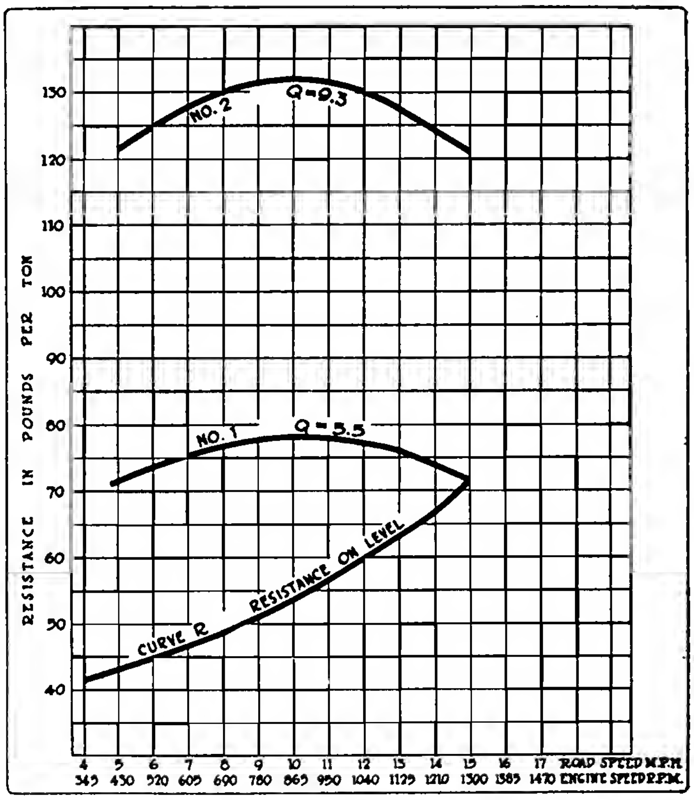

Fig. 2—Curve R is from Mr. Wimper's formula: Resistance = 40 + 14 $\frac{V}{10}{}^2$ lb. per ton where V is speed in M.P.H.

The maximum gradient up which the engine would drive the vehicle on top gear is represented by Curve 1 in Fig. 3.

Engine Sizes for Hill Climbing

The modern lorry is expected to be able to climb gradients of about 1 in 30 on top speed with full load, and we may take this to be a reasonable figure. From Fig. 1 it is found that the engine has its range of highest torque at about 1000 r.p.m. or 11½ m.p.h., and this is taken as the climbing speed.

ηp is 87 lb. and R is 58.5.

The total resistance due to R and the incline is

$$W\left(R + \frac{2240}{30}\right)$$

or

$$W\left(\frac{1755 + 2240}{30}\right)$$

$= W\frac{3995}{30}$ (approximate total resistance = 133 lb. per ton)

(*Continued on page 476.*)

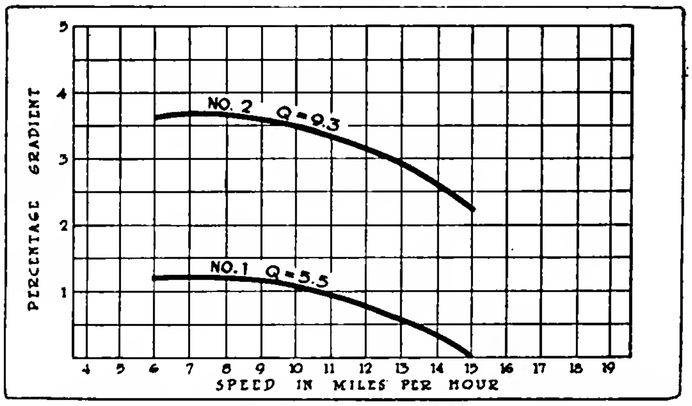

Fig. 3—Hill climbing capacity for "Q" = 5.5 compared with same for "Q" = 9.3

Proving New England Prosperity

Boston Show Discloses Demand Equal to Expectations—Buying Active Throughout Winter — Many Closed Cars Wanted

By David Beecroft

BOSTON, March 7—Last week THE AUTOMOBILE stated that 1916 would be one of the most prosperous years for the automobile in New England. This week, after spending two days at the fourteenth annual automobile show now running in this city, we are led to confirm the fact, not because of crowded exhibits and aisles in the show, but because we have talked with a majority of the Boston distributors who handle New England through scores of agents, and because we have seen the Boston populace and the New England populace look over cars and buy them. Only two days of the show have passed. Five more remain, and the story that could be written if the complete history of the business of show week could be accurately collected would be one of the most impressive automobile stories that New England ever heard. The out-of-town dealer tells the same story that the Boston distributor tells, a story of unprecedented demand for cars, a story of unparalleled wealth through the six States, and a story of greater confidence than heretofore experienced.

Last week the prediction was made that New England could absorb 50,000 cars this year. She can readily do this if the cars can be secured, if shortage in materials does not restrict production in many factories not fortified against the days that seem in store in the metal world. If New England can get the cars when the buyers want them she can absorb 60,000 machines; in fact, the demand is here for 75,000 machines.

The possible shortage of material has permeated the farthest town in Maine, in New Hampshire, in Vermont as well as the three southerly States, Massachusetts, Rhode Island and Connecticut. New England is much closer to the metal market than some other parts of the world—closer than the great Mississippi Valley with its almost limitless areas of productive acres. New England has breathed machinery for years and knows of the rising prices of metals and the possibility, grave possibility, of not being able to perhaps secure as many cars a few months hence as she would like to receive. New England remembers the past season when, if more cars could have been had, much more money would have been made.

This combination of circumstances has brought about an entire change in conditions throughout the six States and particularly through the three northern States, Maine, New Hampshire and Vermont. Never before has there been such a generous and widespread storing of cars by dealers in these States during the winter months. Heretofore the New England dealer was adamant to all solicitations of the maker and the distributor to store cars and have them ready for spring delivery. To-day he is stocking up in an unheard-of manner, and apparently for varied reasons. He knows the money is in his territory to buy cars, he knows that the material market is rising and he feels in his very bones there is grave probability of a car shortage when the big selling season comes. He wants to be protected at that time. He has turned over a new leaf in automobile selling. The arguments that manufacturers have been hurling at him year after year have at last fallen in fertile soil. The old New England tradition appears broken. A new order has set in.

The Boston distributor has come to the dealers' assistance in this storing work by making the storing process as easy financially as possible. Often the dealer has to give a deposit of but $100 per car, and in addition pay interest on the money the dealer has invested in it and carry the insurance, if he takes such protection, which the distributor generally requires. This proposition, attractive as it is, lacked appeal a year ago. To-day it is a potential.

The used-car market has experienced a desirable stimulation. It is perceptibly better than a year ago, notwithstanding the fact that many distributors in Boston are stocked up with far too many cars taken in in trades. To-day these distributors, some of them dealers, hope to find a ready

Invention, Progress, Industry and Success uphold the giant wheel market, due to a possible lack of new cars. Already this is having its effect, and were it not for the heavy snow generally throughout the six States which has been on the ground for the past two weeks, the used-car business would be moving at a very healthy rate to-day. New England freezes up in buying automobiles much in proportion to the temperature and snow condition. Hundreds of sales have been delayed by the snow. Opening conditions are looked for and anticipations are for the biggest March and April of years. Some predict a very short active selling season. They go so far as to say that by May 15 the selling season will be over. Definite reasons for such an opinion are wanting. The answer seems to be in the atmosphere.

Carload Shipments All Winter Through

Reverting to the question of winter deliveries to dealers throughout all New England: Carload shipments have been made to the several States all winter, a condition not existing heretofore. A Maine dealer recently placed an order for fifty cars. In Vermont such centers as Rutland, Burlington, St. Johnsbury and Barre have been taking deliveries constantly. There is a tendency in these cities to keep cars more in commission than formerly, but only a very small percentage of the sales are going into actual use. Dealers in these cities are making deliveries, although the ultimate purchaser is perhaps not putting the car into commission. He is taking time by the forelock. He wants to know that he will have the car, and that new turns in the war, new developments in Washington, or other unexpected conditions such as shortage of materials, shortage of cars, etc., cannot rob him of his machine.

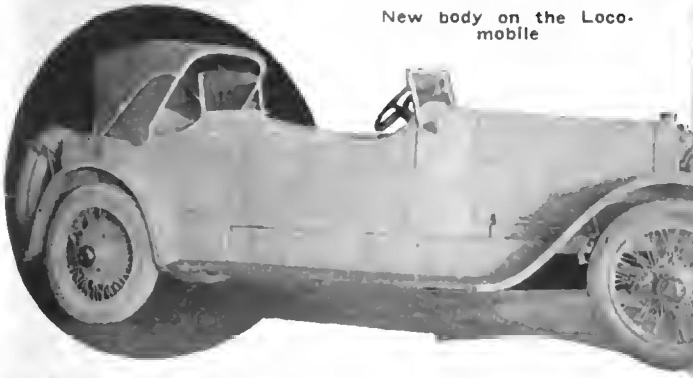
Reverting to the Boston show: The show is revealing many changes in the general trend of the industry in the six States. Closed cars are making very pronounced headway, this not only in Boston, but in all the States. The progress is slow in such Vermont centers as Burlington, Rutland, Montpelier and Barre, where very few cars are seen on the streets in the winter. The cities in Maine along the Atlantic Coast enjoy a climate moderated by the salt waters of the ocean and so can use their cars to advantage all winter, while those cities farther inland have to lay them up because of heavy snow falls and cold weather.

The sedan is proving a popular New England car, not only in Boston, but outside as well. It is the ideal family car. The same is true of the detachable winter body. Coupes are not in demand. The conventional coupe accommodates three people, and for a winter vehicle that is not enough. There must be accommodation for four. Boston is a good limousine town. The Berline is not known at all.

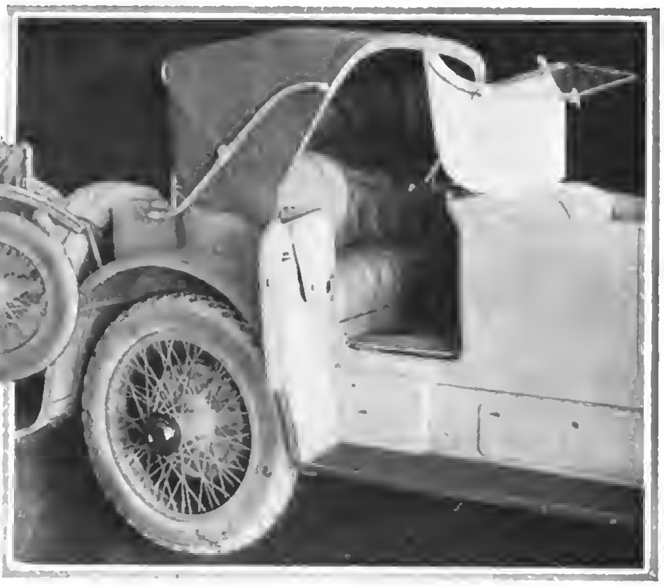
An official count of the different styles of bodies at the show generally reveals the types of bodies most in demand. This cannot be taken without modification, because to-day the selling period of closed cars is over and naturally touring cars and roadsters are featured. There are more closed cars shown than might be expected because several Boston dealers were not able to get their closed types early in the fall. Instead of getting them in October, they came through in December and then in small quantities.

Many distributors are quite emphatic in their condemnation of manufacturers who disappointed them so seriously in the closed car business. Some of the makers in turn were held up by labor troubles. The net result is that the maker does not start his closed car business early enough. He should lay his program out in May and have them in the dealers' hands in September. This is true for Boston and is equally true for Minneapolis, Kansas City, Omaha and many

Paul Revere Hall, on second floor of Mechanics Building, given over entirely to Mitchell exhibit. At the far end is a real full-sized touring car set in a huge painting of New England scenery



New body on the Locomobile



other Western cities that are rapidly developing closed car business.

Now the count: Boston has 273 passenger vehicles of all kinds in the show. There are but three electrics and three steam. Touring cars are the big leaders, there being twice as many of them as roadsters. Limousines are third, then come detachables or winter bodies and closely grouped on about even terms are coupes, sedans, cabriolets, and town cars.

The figures are: Touring cars 120, roadsters 60, chassis 32, limousines 21, detachables 9, cabriolets 6, town cars 5, coupes 4, sedans 4, landaulettes 2 and berlines 1, and a few miscellaneous types. The three electrics are closed types.

A Fine Truck Display

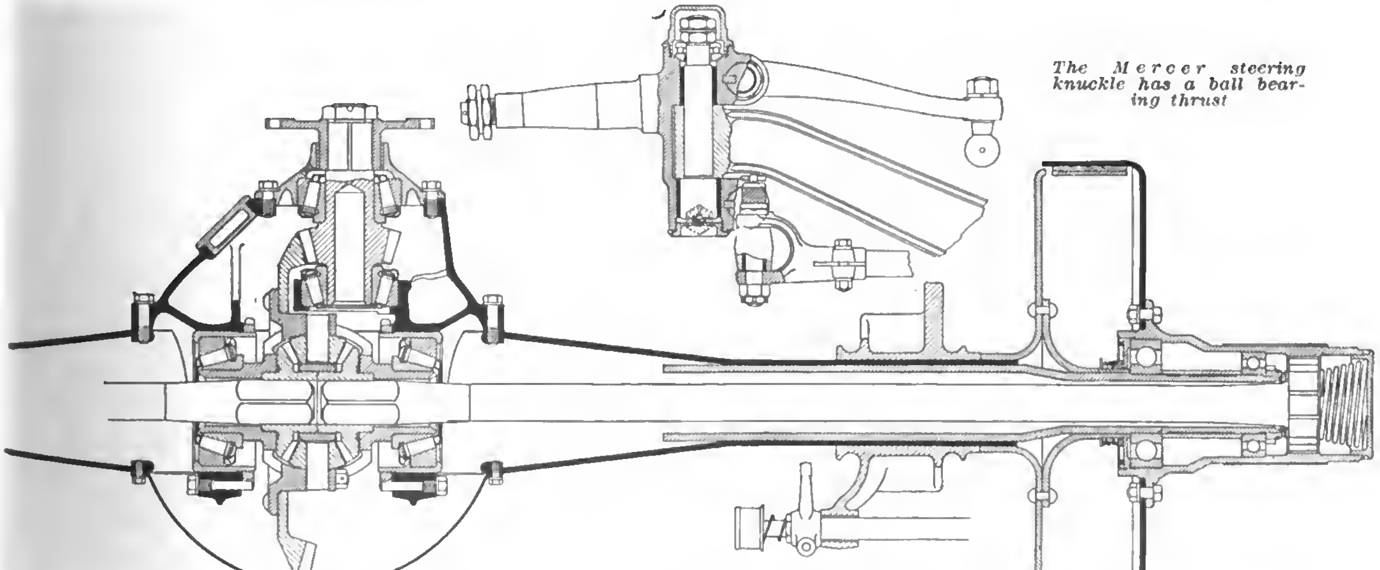
But this is not all. The Boston show has thirty-eight different makes of motor trucks; in fact, the greatest truck show of the year. Never before have there been so many trucks exhibited at a passenger car show. Some years ago Boston had a separate truck show a week after the passenger car show. The attendance was not up to the mark and the separate show was discontinued. To-day there is not room in the basement for the trucks.

The exhibit of electrics is poorer than ever before seen in Boston. There are anly three vehicles. Boston is not a good electric town with its narrow streets and its shopping district boxed up in the heart of the city. Add to this the fact that the city regulations will not permit unattended vehicles standing by the curb more than a certain length of time and you are at once convinced why women have not taken kindly to the electric.

Boston always brings out something new in bodies, styles not seen at either New York or Chicago. Some of these are the creation of local body builders. Others have originated in New England, where there are many high-class body manufacturers. The most original body style seen and one which gives promise of being largely copied is a four-passenger Locomobile touring type with a hinged cowl and windshield for the tonneau. The cowl carries a sloping windshield just as the dash cowl and practically as large. This tonneau cowl hinges to the back of the front seat and is raised when passengers enter. The windshield is back close to the passengers. A victoria top is used. It is the first time this hinged form of cowl and windshield has been seen.

Kissel has a new form of four-passenger roadster with disappearing rear seats. The front seats are individual with a passage between them to the rear, and when the rear seat is folded into the body and out of sight this passage is filled by a hinged filler board. This filler board swings back into the floor when the rear seat is opened. Rear seat passengers slt side by side, and there is comfortable room for two. The body was built by McNear, a local builder.

A high-water mark in exhibit ideas is carried out by the Mitchell distributor, the Pope-Hartford Co. of Boston. The exhibit is staged in Paul Revere Hall, a separate room in the show building, as illustrated opposite.



The Mercer steering knuckle has a ball bearing thrust

Features of the Mercer axle are the light casing, the double support for the drive pinion and the spring retained drive shafts (See page 452)

Refinements Feature New Mercers

Two Chassis, Similar Except for Wheelbase, and Four Body Models Continued—The Improvements Made Are Principally in Bodywork

SERIES 22-72 Mercer, which has recently been announced, is a continuation of the line introduced last season with minor refinements. Following Mercer traditions, the series is equipped with four-cylinder motors, and throughout, the new models adhere very closely to their predecessors of the 22-70 line. However, there have been a few refinements during the year.

Four different body styles are marketed this season. They are a six-passenger at $3,000, a four-passenger at $3,000, a runabout at $2,900, and a raceabout at $2,750. This also is in accordance with the practice of last year. The six-passenger touring model is a roomy vehicle adapted to family use, while the four-passenger is a sporting model and is designed for those who want a light car with quick acceleration and speed. Both of these models are mounted on chassis of 132-in. wheelbase.

The runabout and raceabout are built on chassis which are similar in practically every particular to the touring chassis, except that the wheelbase is 115 in. The runabout is suitable for two-passenger touring, while the raceabout is confessedly a speed car and is guaranteed to be able to make a mile in 48 sec. or, in other words, to travel at the rate of 75 m.p.h.

The Mercers of last year were distinguished in the touring bodies by the graceful center cowl, and the same idea has again been carried out, but the interior work of the body has been improved considerably. For instance, the auxiliary seat compartment of the six-passenger is finished in black walnut paneling. The extra seats are hidden from view when not in use by doors which can be rolled out of sight similarly to the cover of a roll-top desk, and another convenience is a special compartment built into the right front door to carry a complete set of tools.

Under the center cowl of the sporting model are three separate compartments also covered with black walnut paneling, the center compartment being sufficiently large to carry a good sized suitcase, while the other compartments on either sides are smaller and can be used for carrying such articles as Thermos bottles and miscellaneous items.

Details of Mercer 22-72

Number of Cylinders	Four
Shape	*L Head*
Bore	3¾
Stroke	6¾

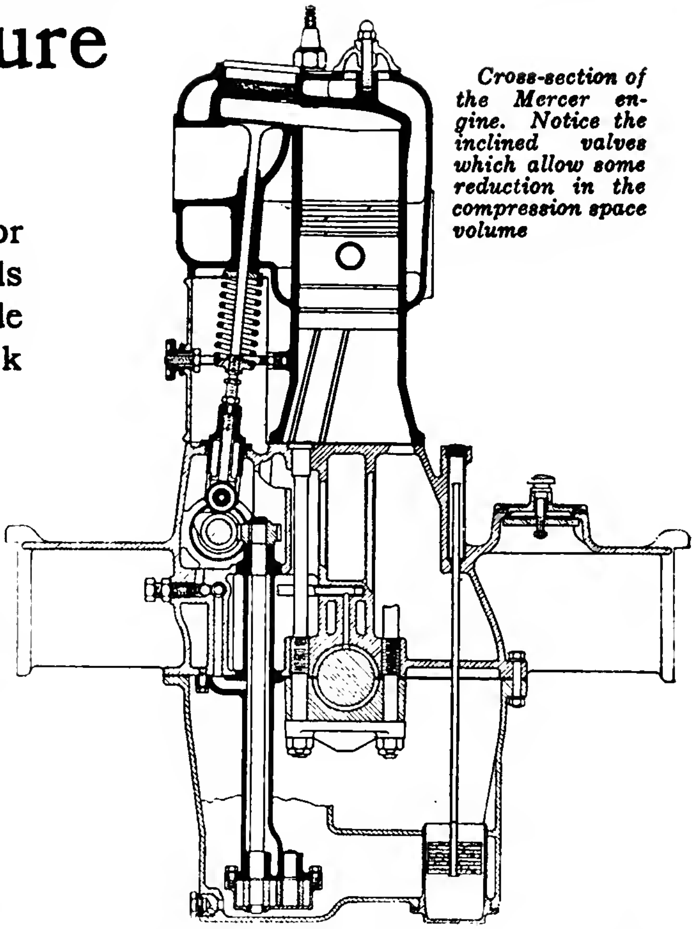
Lighting System	*U. S. L.*
Clutch	*Dry Disk*
Gearset	*Four Speed*
Wheelbase	115
Front Tires	32 *x* 4
Rear Tires	32 *x* 4
Type Rear Axle	*Full Floating*



Cross-section of the Mercer engine. Notice the inclined valves which allow some reduction in the compression space volume

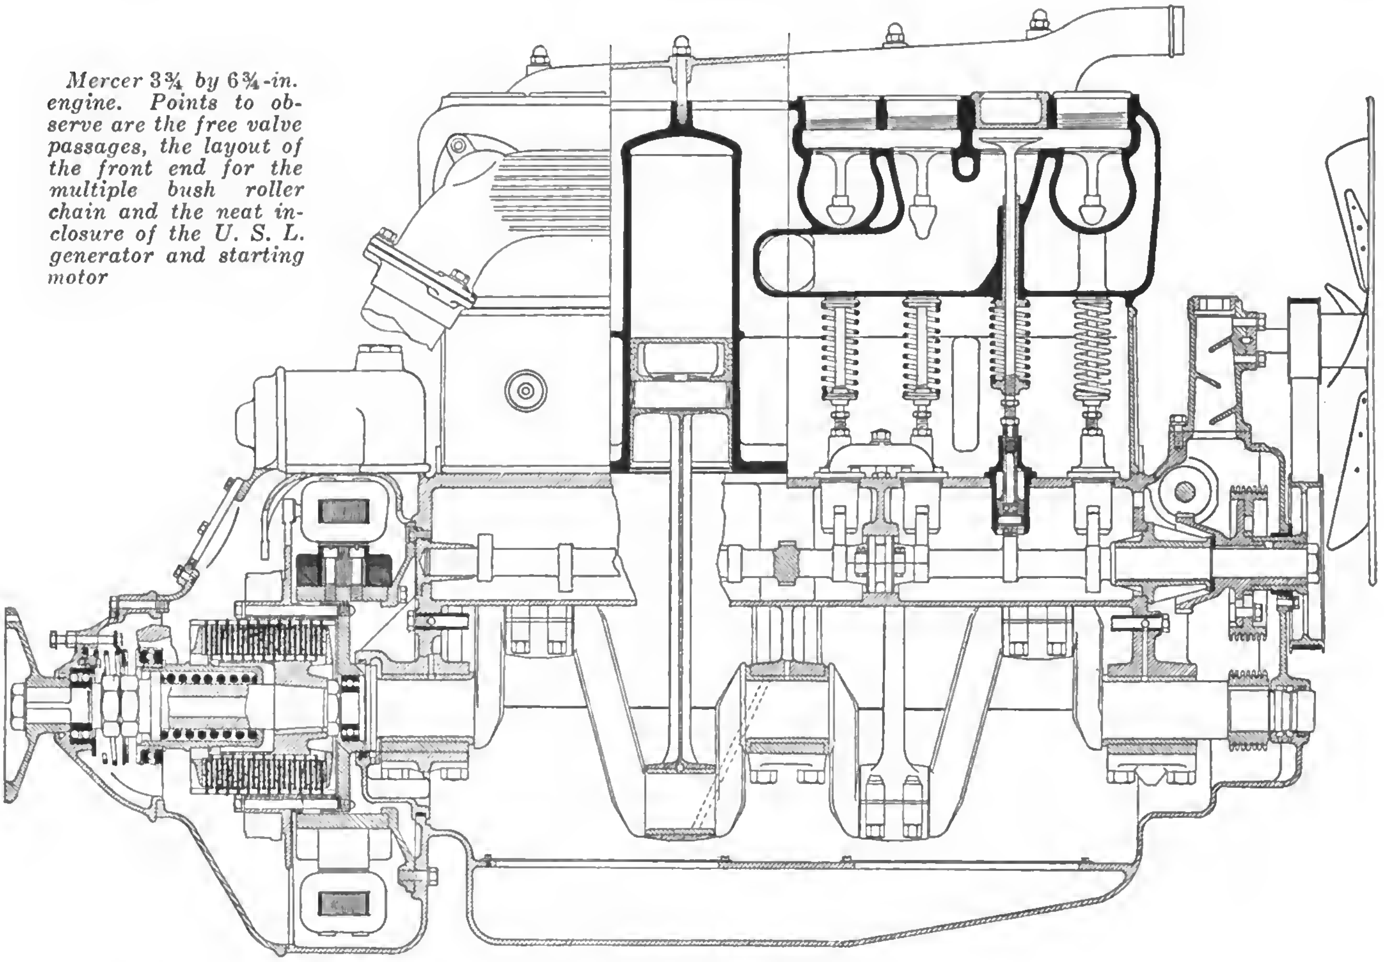
The Mercer car occupies a position in the automobile world that is very nearly unique. It is a car built for a class of buyer that is not very large, and it is thus a machine which has but a few direct competitors. The total number of cars being built in America for this special class of consumer is to be reckoned in hundreds rather than in thousands.

Probably the Mercer is the most European engineering job being made in America to-day, being a high efficiency four of considerable power, capacity for very high speed and a very high accuracy of finish on all parts. In addition it has other features that are considered typically European, such as the powerful transmission foot-brake, the amidships gearbox and last, but far from least, the body lines. In the body the Mercer engineers have made a wonderfully happy combination of American and European ideas. The outside lines are unexcelled by any stock car in the world, the internal fittings combine comfort and convenience to a high degree. It is essentially a British style of body with the best of American and French ideas added to enhance its qualities.

A Really Good Four

It has often been said, and truly, that the four-cylinder engine lacked a proper appreciation because there were so few fours made with the care that is possible in a car demanding a high price. The Mercer engineers, like many others who have not yet shown the courage of their convictions, believe that a four can be made to provide every quality of performance that is necessary or desirable, and have chosen the dimensions of 3¾ by 6¾ in. giving a piston displacement of 298 cu. in.

Since this is not the customary view, it may be well to begin by giving some attention to the performance of the car, before describing it in detail. First, as regards high gear ability, the stock model handles well from speeds of 8 m.p.h. upward, it will run more slowly than 8 m.p.h., but that is the lowest speed that the average driver would use



Mercer 3¾ by 6¾-in. engine. Points to observe are the free valve passages, the layout of the front end for the multiple bush roller chain and the neat inclosure of the U. S. L. generator and starting motor

normally, in fact the change to third gear is so easy that many a man would not employ the high gear for speeds much under 12 m.p.h. This figure of 8 m.p.h. is not a bottom limit as are the 2 m.p.h. speeds possible for some other cars with lower gearing and more cylinders, it is about 2 m.p.h. higher than would ordinarily be obtainable with a six or eight geared to the same ratio.

After 12 m.p.h. is attained it is not possible to distinguish the impulses so as to pick out the engine as being a four, and then, as the speed rises, up to the maximum there is no detectible periodic vibration. Vibration is present of course, but it is extremely small in amount and not perceptible till crankshaft speeds over 2000 r.p.m. are attained. At no speed is the vibration so great as that observable at some speed or another on all but a very select few of the sixes and eights.

Engine Speed Runs High

The speed capabilities of the engine are quite unusual. On second gear on a good road with top up and two passengers the writer obtained 46 m.p.h. and on third gear under the same conditions, 60 m.p.h. On the fourth gear, which is the direct drive, 65 m.p.h. was attained easily, road conditions at the time preventing any greater speed. At 65 m.p.h. the engine is running easily, and evidently the car would touch the 70 mark or a little over.

The gear ratios are, 3.6 to 1 on high; 5.4 to 1 on third; 7.9 to 1 on second and the low speed ratio is 13.8 to 1. This means that at 46 m.p.h. on second the engine is turning at 3800 r.p.m. and at 60 m.p.h. on third it is making 3400, these corresponding to piston speeds of 4270 and 3820 ft. per minute. These figures give an idea of the engine's elasticity and serve to show that the almost total elimination of vibration is a testimonial to the care taken in the design and in the manufacture.

A short time ago the Mercer had a balanced crankshaft, but this has now been discarded, as it is found that the same results are obtained with the conventional type. An idea of the strength is given by the dimensions, the diameter of the main crankshaft journals and crank pins being 2⅛ in. A rather unusual feature of the bearing design is that the front and rear bearings are both the same length, 3⅝ in., the center bearing being 3⅛ in. The 2⅛ in. diameter gives a bearing speed of 556 ft. per minute per thousand revolutions. Since the stroke is 6¾ in. the piston speed at 1000 r.p.m. is 1125 ft. per minute; almost exactly twice the bearing speed.

On high gear the piston displacement is 390 cu. ft. per mile.

Vibration Notably Absent

Returning for a moment to the matter of vibration, since its elmination from the Mercer is one of the car's most striking characteristics, some interesting things have been done to get the good effect obtained. For instance the pistons are Lynite permanent mold aluminum of a lighter section than usual, the webs beneath the head having been removed because it is thought their expansion may cause piston distortion. Each piston has two rings only, oil being kept down by the use of a long skirt and the weight of the piston assembly with rings and wrist pin is only 1.15 lb. Another factor in vibration elimination is the use of long connecting-rods, these being 15 in. center to center, the ratio connecting-rod to stroke thus being 2.22. This, of course, cuts down the unbalanced forces to some extent as it is a perceptible amount longer than the conventional. The connecting-rod weighs only 3.3 lb. being a highly finished I-beam forging.

Reciprocating Parts Are Light

Lightness of reciprocating parts is studied also in the valve mechanism, both the valves themselves and the tappets being as light as considerations of strength will allow. These parts can be studied in the drawings which also make clear the method of assembly of the four-bearing camshaft. For the latter a very interesting form of drive is used this being a multiple bush roller chain. In effect this is a number of narrow roller chains side by side, but the rivets or pins pass right across the whole row so that there is a series of small rollers separated by side plates. This type of chain operates as quietly, or even more quietly than a silent chain, and does not required any adjustment because a spring-supported idler bearing upon the back of the chain can be used to maintain the tension. It is a light form of chain camshaft drive and highly efficient.

Lubrication is a high pressure system, all the crank and connecting rod bearings receiving a supply, together with separate feeds to the camshaft bearings, the chain and the chain idler. In the cross section of the engine it will be noticed that the oil filling cap is located on one of the crankcase arms in a position of ideal accessibility.

Transversely across the front of the engine is a shaft driven by skew gear from the camshaft, this having the magneto and water pump mounted at opposite ends the thrust of the water pump being balanced by the thrust of the skew gear.

The cylinders being an exceptionally neat block casting the carbureter bolts directly to a flange on the left side the intake passage passing between the middle cylinders and then running fore and aft in close proximity to the separate exhaust manifold, this giving the necessary warmth. In the sections of the engine it will be noticed that the water spaces are proportioned very well, giving a free flow everywhere. The U. S. L. flywheel generator and starting motor is entirely inclosed within the crankcase, a hand hole giving access to the brushes and to the dry-disk clutch. This clutch, by the way, has twenty-four disks and operates with a very light pedal pressure; it is one of the easiest clutches to control in use to-day. Having a small diameter center, and a clutch brake, the inner member has but little flywheel effect, making it easy to change gears without much regard to the speed the car is making.

The engine bolts rigidly to the frame having four supporting arms on the crankcase and the amidships gearbox is brought into alignment, the two being connected by a flexible coupling. Placing the gearbox well back in this way permits the gearshift lever and the brake lever to be brought up conveniently from the top of the box and yet stand in the correct position relative to the driver. There is no especial peculiarity in the gearset, it being characterized by large diameter shafts and wide gears.

Brakes Are Large in Area

Behind the gearbox is the foot brake, this having expanding shoes faced with Raybestos and a steel drum with cooling ribs turned upon it. Its dimensions are 11 in. by 2½ in. and it has immense power combined with smooth action. The easiest way to obtain smoothness in a brake is to provide large surfaces, and it may be interesting to calculate the effective area of the Mercer transmission brake. On the assumption that of the total circumference of the drum the brake shoes only bear effectively on two segments of a 90 deg. angle, and this is the usual assumption, the Mercer brake area works out at just under 14 sq. in. The expanding brakes on the rear axle, operated by the hand lever, are 16 in. by 2½ in. and thus their combined effective area is 40 sq. in. At 20 m.p.h. the rear wheel is making 210 r.p.m. and, since the gear ratio is 3.6 to 1 the rubbing speed of the transmission brake is 36 ft. per second, as compared with 14 ft. per second for the road wheel brakes. Multiplying rubbing speed by area engaged and we get figures of comparative effectiveness for the road wheel and transmission brakes of 560 and 504 respectively.

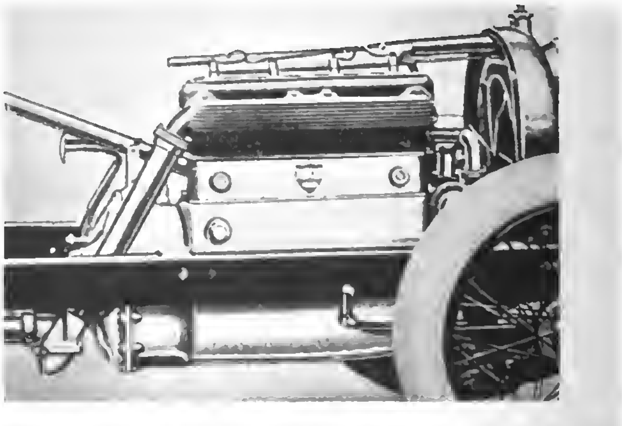
In the rear axle, lightness has again been a consideration, but the particular features being the spigot bearing for the bevel pinion, shown on page 449, and the method by which the driveshafts are slid in through the hubs and held secure against rattle by springs. There is no torque rod, the axle being bolted directly to the springs, which are underslung.

Semi-elliptic springs are used both front and rear, the latter being 59 in. by 2¾ in.; all the shackle bolts are hollow and fitted with oil retaining lubricators.

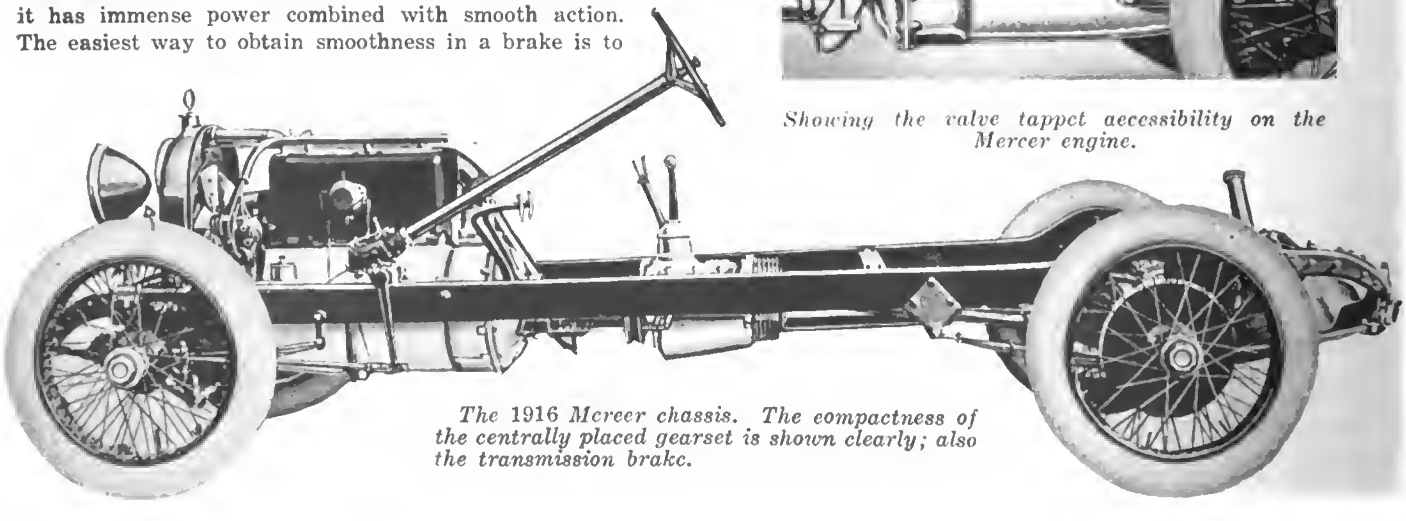
Great care has been taken in laying out the steering, which is irreproachable for lightness and accuracy. At 60 m.p.h. it operates as easily as at twenty and this is doubtless largely due to the use of ball thrust bearings for the steering knuckles and in the steering worm box.

Accessibility a Strong Feature

As to the detail, this is equally well worked out, and accessibility is a strong feature. Brake adjustments can all be made readily by large hand nuts situated beneath the front floor board, the carbureter with its vacuum fuel feed has no other parts near it, the magneto is likewise clear of all obstructions and the valves have nothing in front of them. This accessibility on the engine is certainly aided by the U. S. L. starter, since this needs no mechanism outside the flywheel case.



Showing the valve tappet accessibility on the Mercer engine.



The 1916 Mercer chassis. The compactness of the centrally placed gearset is shown clearly; also the transmission brake.

This illustration shows how two cars are loaded in one end of the freight car, two others being in the opposite end, while the fifth car stands in the middle. The latter goes with the top folded

New Kelly-Springfields Have Worm Drive

Six Models With Chain Drive and Two With Worm Drive Now Form Kelly Line

K-32 1½-ton Kelly worm driven chassis

THE Kelly-Springfield Motor Truck Co., Springfield, Ohio, has been one of the last of the larger producers to abandon the chain, although such abandonment in this case only amounts to its adoption as an alternative on two of the lighter models, there being six chain-driven sizes still in the catalog.

The two newcomers are of 1½- and 2½-ton capacity and are similar in almost every respect, excepting only final drive, to two chain-driven models of the same capacity. In addition to these there are 3½-, 4-, 5- and 6-ton models, all chain-driven. The last four of these are the same as announced at the beginning of the year and listed in THE AUTOMOBILE'S specification tables published Jan. 13. The 3½-tonner is the same vehicle as was formerly built for 3 tons, but with some heavier parts to sustain the increased load. The 2½-tonner is a similar outgrowth of the former 2-ton model. The 1½-tonner is practically as before, the 1-ton size being dropped.

Adaptation of the worm drive to the Kelly chassis has not entailed any other radical changes. The same motor, under its French hood, with drive through a torque-tube-inclosed shaft to a midships gearset is employed, and the frame remains of pressed steel in a flexible form, there being only three cross-members, with round bars supporting the spring shackles.

The driveshaft has been connected with the driven gearset shaft with a universal and carries another between it and the axle. The gearset occupies practically the same position as in the chain-driven models and is suspended on a wide yoked cross-member drilled to receive the rear flange of the gearset on the same jig as is the jackshaft flange.

The axle, while containing a Timken worm and gear, is otherwise of Kelly manufacture and is of the semi-floating type. Radius rods are used, as on the chain-driven models, with the torsional stresses falling on the springs. A feature of the Kelly spring suspension is that the right rear springs contain one leaf more than the left rears, thus allowing for the excess load imposed on the right spring when running on the usual crowned road.

Brakes on the new models have been placed on the rear axle, side by side, and are expanded by cams of unusual size. The brake carrier is a solid casting which includes the spring perch and wheel bearing housing and bolts directly to the axle housing. It is lubricated by one grease cup of large size, supplying lubricant to all parts contained in it excepting the brake-shoe pivots.

The new models are subject to the same wide range of wheelbase options that is offered in the chain-driven ones, affording load platform lengths of from 9 to 15 ft. back of the driver's cab.

From the motor the drive is taken by a cone clutch, mounted on the end of a rigid torsion member extending with its shaft back to the gearset. This eliminates any flexible joints between these two members. The gearset affords three forward speeds on the selective plan.

The steering wheel is to the left with central levers.

Below—Brake and radius rod on K-32 1½-ton Kelly worm driven chassis

The History of the American Automobile Industry—20

Lenoir Experiments Advanced Knowledge—Steam Engine Taken as Basis and Explosion Used to Heat Air—Engine Driven by Air Expansion

By David Beecroft

LAST week the Perry explosion engine of 1844, incorporating many of the essentials of an internal combustion, was shown as the high mark of American inventive genius of seventy years ago. Now the thread of progress in the internal combustion engine shifts to Paris, France, and instead of 1844 it is 1861, seventeen years later. After Perry the next great forward step was taken by Jean Etienne Lenoir, Paris, France, whose now famous patent shows what a grasp he had on the explosion engine, although even then Lenoir looked upon it more as a modification of steam rather than a complete internal combustion type.

Used Steam System

Lenoir was convinced that he could take a steam engine and, by few changes, convert it into an explosion type. Lenoir did not look upon his engine as an explosion type as we do to-day, but rather as one in which he took in a part charge of pure air, and followed it by an explosive mixture of some hydrocarbon and air. Lenoir then exploded the mixture by an electric spark, as the heat of this explosion was wanted to expand the volume of air, the expansive force of the air driving the piston.

With this partial conception of the internal combustion engine as we know it to-day, it is but natural to find Lenoir's engine very similar in design to a steam engine. The illustrations are taken from his engine as manufactured in large quantities in 1865. At that time over 400 of them were in use in France and 100 had been built in England. To Lenoir belongs the credit of being the father of the practical explosion engine. Previous to his day all explosion engines had been largely experimental. Lenoir in 1861 to 1865 was to the explosion engine what Newcommen was to the steam engine in 1704. Each added the practical touch to his invention.

Lenoir's engine was a double-acting type, an explosion taking place at each end of the piston, steam engine fashion. He used slide valves at one side of the cylinder for the intake air and gaseous mixture and a similar slide valve at the opposite side for the exhaust. The one valve served for intake at each end of the piston and the exhaust valve performed a similar function. These valves were driven by eccentric shafts from the crankshaft (see illustration). The top illustration with a cylinder in section shows intake and exhaust passages very small, but they extended a considerable distance circumferentially, thus obtaining sufficient area. The intake valve operated to first let in a volume of 85 per cent of the combustion chamber of pure air; this was then followed by 15 per cent of explosive mixture.

Lenoir did not have a carbureter in even a vague sense as we know it to-day. Instead he carried the hydrocarbon in a small vessel or boiler. In the bottom of this boiler he placed a coil which he connected with the exhaust jacket of the engine, thus using heat as we do in the carbureter to-day. The heat from the coil caused part of the hydrocarbon to pass off in vapor, and Lenoir conducted it directly into the cylinder.

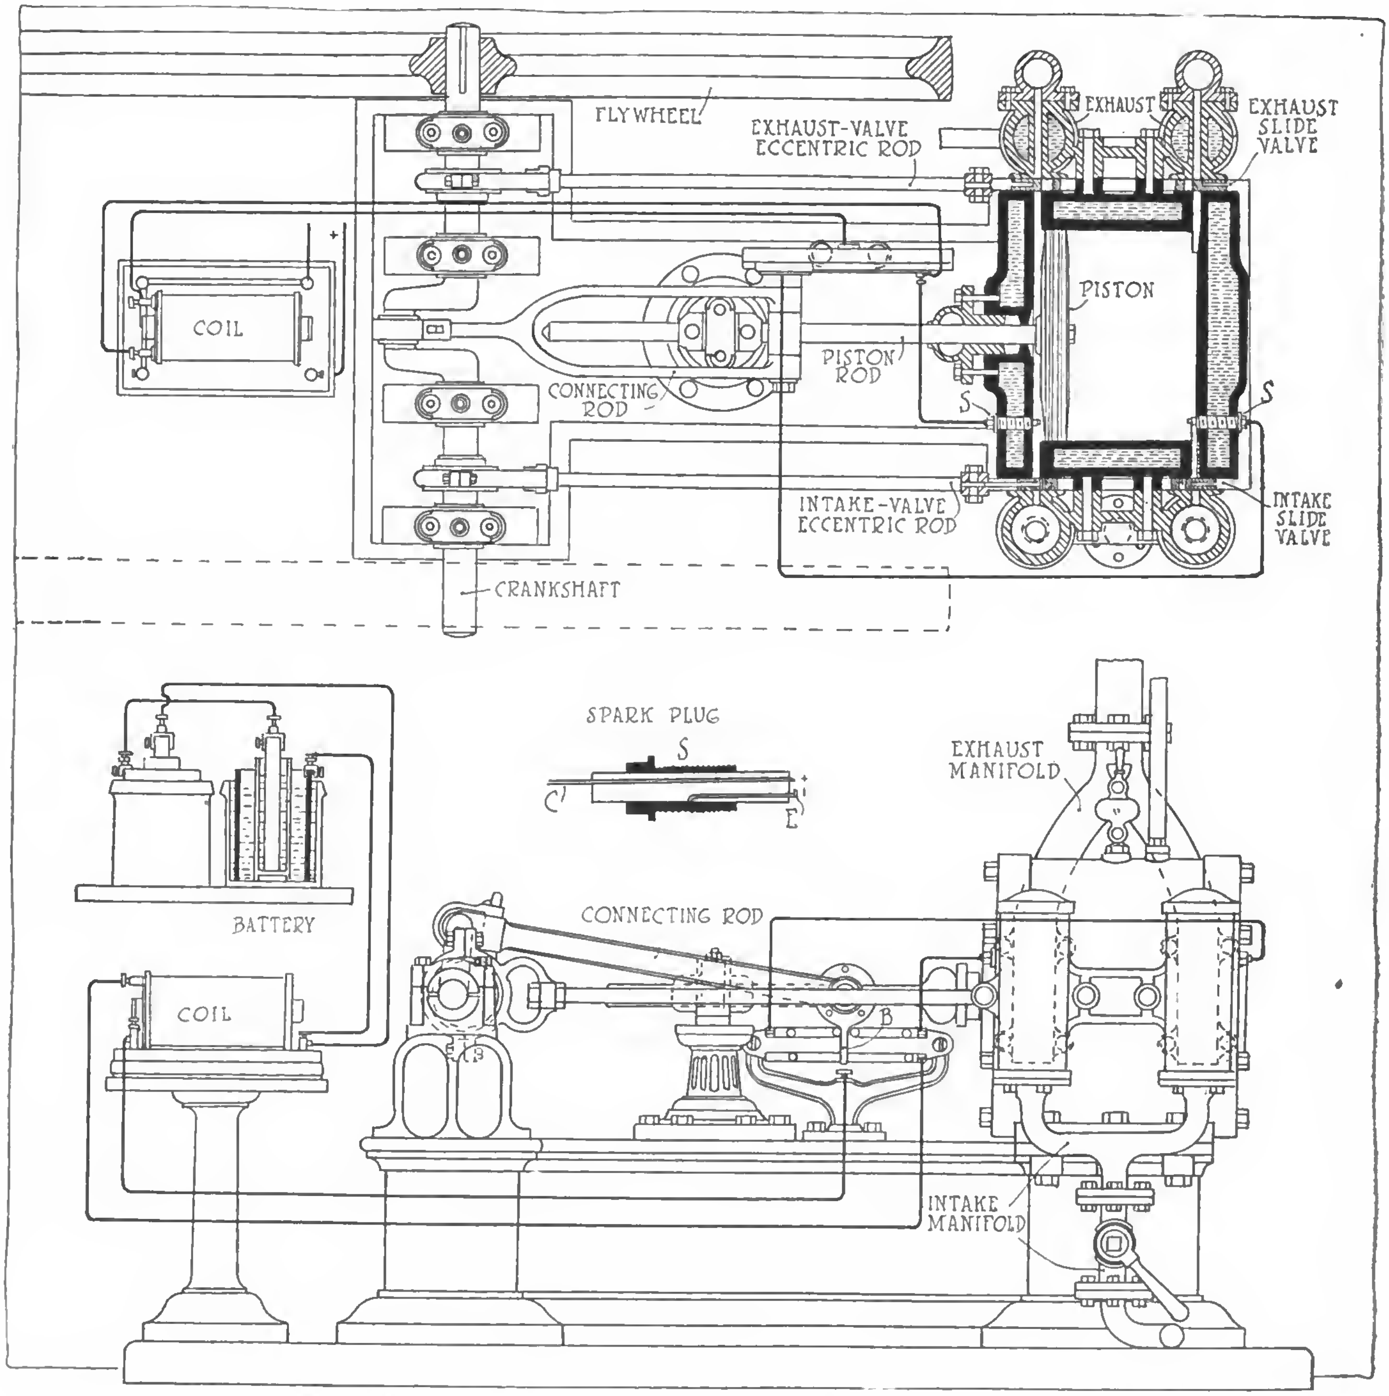
Passing to the ignition system as used by Lenoir, we find him using every essential of modern electric ignition. He used spark plugs (see illustration) that are identical in functioning with those of to-day, and only differ substantially in design in that there was a separate electrode *E* connected with the spark plug shell—the center electrode *C* was practically identical with modern practice.

But Lenoir went farther in his electric system, and was among the first to use the step-up or Rhumkorff coil to give his high voltage current. The low voltage current was taken from a primary battery (see lower illustration). As a means to deliver the current first to one spark and then to the other Lenoir was entirely modern. He attached his distributer *B* to the piston rod and contact was made to the two plugs in proper sequence. In his crude distributer he used hard rubber or gutta-percha in which he embedded the metal segments, practically identical in principle with what is done to-day.

Water Cooled Spark Plug

One feature in which Lenoir was perhaps a little in advance of the art of to-day was in water-jacketing his spark plugs. The illustration shows how the two plugs extend entirely through the cylinder waterjacket. Lenoir waterjacketed his entire cylinder walls and both ends. Although Lenoir had in reality the internal combustion engine as we know it to-day, he was not aware of what really took place within the combustion chamber, or if he later became aware of it, this fact remains that when his patent was issued he had not such a conception. His patent has only one claim which clearly sets forth his conception of the engine. Here it is: "The arrangement in an engine substantially as described, of the parts for the admission to the cylinder successively of air and inflammable vapor or gas in such requisite quantities and proportions as that the former (air) shall act upon the piston by expansion on being heated by the ignition of the latter (gas).

Lenoir very clearly set forth the fact that his engine was not a gas engine, but rather an explosion one. In his patent he sets this forth in the following terms: "My intention relates to engines in which the motive power is air diluted or expanded or heated by the combustion of an inflammable gas; and it is based on two fundamental principles: First—the application or the combination or mixture with atmospheric air of lighting gas or any other inflammable gas; and second, the simultaneous action of both in an engine deriving its elements of function from electricity and operating substantially in the manner of a steam engine. I employ gas and air in the proportions of 15 and 85 per cent; thus in my engine the function of the gas is as a fuel that can be ignited without producing any shock, for the purpose of heating the air that is mixed with it. The air thus dilated acts on the piston as steam in a steam engine."



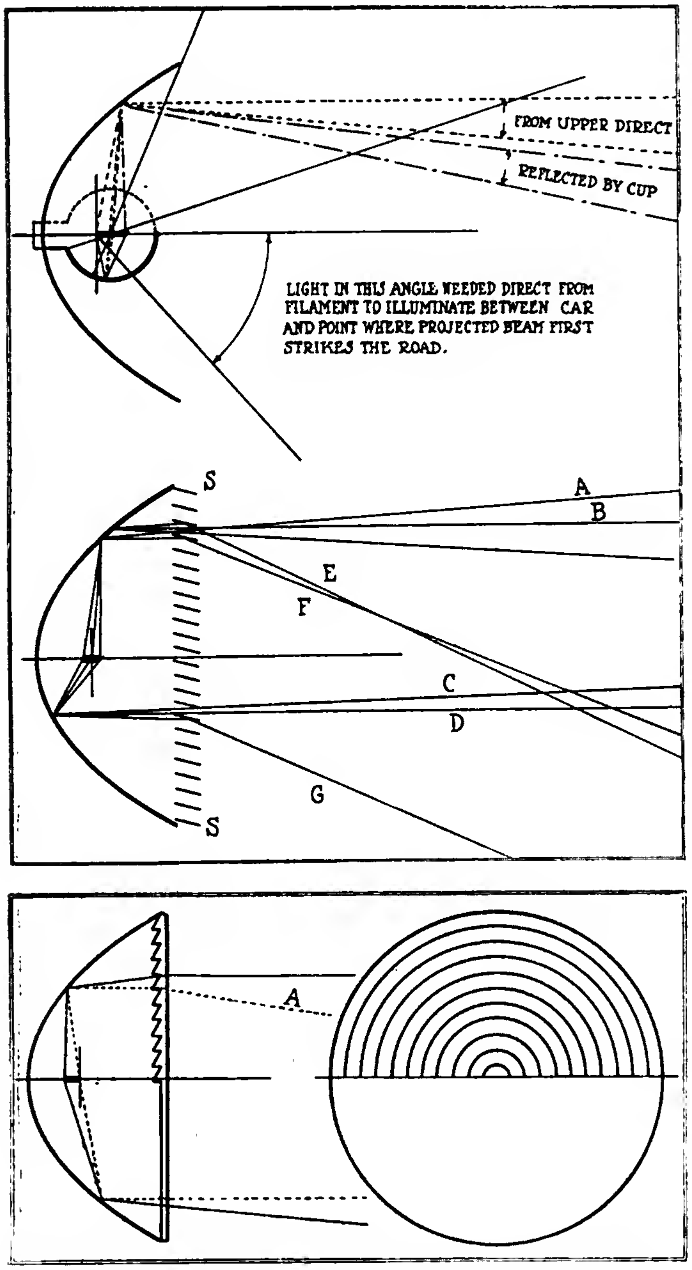
Lenoir's explosion motor of 1861, the first practical explosion motor built. Over 400 of these were made in Paris and 100 in England. Lenoir used modern electric ignition for the first time. His engine used slide valves

What Good Lighting Really Is[*]

Automobile Lighting Analyzed from the Lighting Viewpoint

By Emerson L. Clark

THE reflector does not actually have to be cut away, it is sufficient to put a shield over half of its surface or over half of the glass front of the lamp. However, if this shield is over the lower half of the glass front the light on the road directly from the filament is cut off and this light is needed to illuminate the space between the car and where the beam first becomes effective. The change in the road surface covered by changing the same reflector and light source to this type of beam is indicated in Fig. 6 by the difference in the area within the full and the dotted lines. The space between the lamp and where the beam becomes of effective width depends upon light directly from the filament for illumination. The absence of such light will be quickly noticed. Instead of putting an opaque screen over half of the lamp front, use has been made of a translucent diffusing screen; this absorbs and scatters light from one-half of the reflector so that its glare is reduced. This increases the illumination near the car, but does not appreciably increase the illumination at a distance over what would be obtained by the opaque shade. This translucent diffusing screen has two defects: First, unless it is very dense it will glare when a high candlepower bulb is used and the glare region is a large one; second, the strong scattered light thrown upward will cause blinding of the driver in fog and snowstorms, as was explained before.



Figs. 16, 17 and 18, showing effect of silvered bulb, of light-deflecting parts and of a prism front glass

Half Light Wasted

The great disadvantage of these various methods of using one-half of the reflector to get an improved distribution is that about one-half of the light that was in the old type of beam is wasted and the intensity especially at a distance is reduced.

Fig. 20 indicates a reflector construction which produces the same type of distribution but puts into the beam the light from both halves of the reflector. This reflector is constructed with an offset on a horizontal plane and the focus of the lower half is near the front end of the filament and the focus of the upper half is near the back end of the filament. In this position each half throws a beam having the distribution above described for a half reflector. The beams from the two halves superpose a short distance from the lamp and the intensity is doubled all over the field. There is an additional advantage over the single half reflector, in that slight irregularities in the single half reflector beam are smoothed out when two beams having different irregularities are superposed.

When properly made, using the correct separation of the foci of the two halves and used with a bulb having an axial length of filament a little greater than the separation of the foci, this reflector will give better lighting with the same candlepower than any other known arrangement. These reflectors are best made with dies from a single piece of metal. The slide shows a lamp containing a reflector of this type.

Fig. 18 shows a construction which was designed to produce the same results as the reflector above described. In this construction the glass front is moulded with a series of concentric semi-circular prism rings covering the upper half of the lamp front. The filament is drawn to the rear of the focus so that the uncovered half produces the desired distribution before mentioned. The prisms on the upper half refract the rising cones of light across the axis, thus superposing them on the beam from the lower half. The simple theory of this device would indicate that it should be very good, but there are a number of circumstances that combine to reduce its efficiency. First, if made of a single piece of

---

[*] Concluded from page 415.

glass, it will not be achromatic, the prisms will disperse and spread the light cones, as well as deflect them. The intensity of the maximum is thus reduced. Second, some light is scattered from the risers of the prism steps. Third, molded glass having abruptly changing thickness as the prisms have, often small cooling wrinkles form which scatter light and thus cut down beam intensity and efficiency.

Those types of prism fronts which deflect the top half of the beam downward as a whole without making each individual cone cross the axis are not as good as the above, because the portion of the beam which they deflect has its maximum intensity on the bottom, and as it is deflected downward as a whole the maximum intensity is still on the bottom after being deflected, whereas to produce uniform lighting it should be near the top.

Fig. 16 represents another arrangement designed to increase the light from one-half of a parabolic reflector, while still retaining the desirable distribution which it gives with the filament drawn out of center. To have the maximum effect in reinforcing the beam direct from the unshaded half, the reflecting cup must be truly hemispherical and set with its center coinciding with the center of the bulb filament. This is difficult with many bulbs because the filaments are not in the center of the bulbs. If the bulb filament is located to one side of the cup center the light reflected by the cup forms a real image on the side of the center diametrically opposite from the filament and this image may be considered as the source of all of the light striking the main reflector from the cup. It will form a beam of light which is mostly separated from that formed by light coming direct from the filament to the main reflector. Under these conditions the light reflected by the cup does not reinforce the beam of light cast from the half reflector.

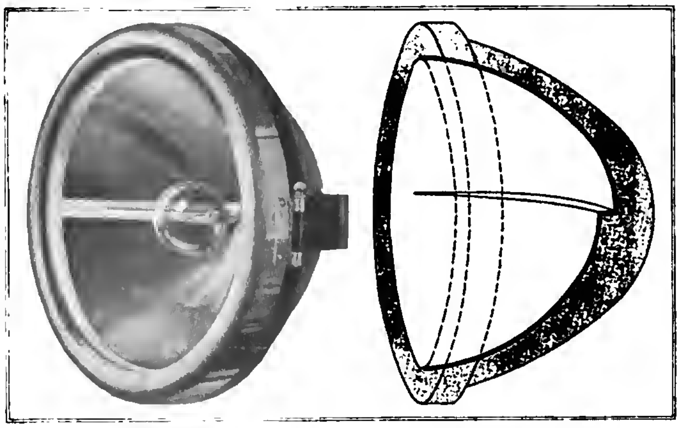


Fig. 20, Details of lamp with divided reflector

If these cups are placed on the lower half of the bulb the light on the road direct from the filament is cut off giving a dark area immediately in front of the car. To overcome this portions of the front of the cups have been cut away to let out the light on the road. This reduces its reinforcing power. Light from a certain zone in the rear of the cup is reflected directly out the front of the lamp and upward without striking the main reflector and contributes nothing to the beam intensity. The light which finally does get into the beam suffers loss by one extra reflection and two extra transmissions through the walls of the bulb. With all of these losses the hemispherical reflector attached to the bulb forms little more than a convenient means of shading one-half of the main reflector, and for this purpose is extremely effective.

Deflecting Slats

Another type of no glare attachment is shown in Fig. 17. In this device a number of closely spaced reflecting slats or louvers are placed across the front of the reflector to prevent rays of light rising above the horizontal. This device prevents glare but does not give effective lighting at a distance. The light acted upon undergoes the loss of an additional reflection and strikes the ground too near the car.

Focusing

With all of the foregoing arrangements for improving the distribution of the light one definite position of the filament gives the best result. This was not true with the plain parabolic reflector where sharp focusing gave a good light at a distance and a poor light near the car, while drawing the filament a little out of focus gave a better light near the car but a poor light at a distance. Some people preferred one evil, some the other, and each focused his lamps to suit his own preference. Interchangeable bulbs under these conditions would be of little advantage because the car owner would not want a fixed focus lamp in which he could not control the focusing. But with constructions designed to give a distribution of light suitable for no-glare lighting and general increased illuminating efficiency as previously described, the case is different. Here one focusing of the filament unquestionably gives the best results and it is not a question of deciding which of two evils is to be preferred as is the case with the plain parabolic reflector. This being the case it would be a distinct advantage to have bulbs that are optically interchangeable, that is bulbs in which the filament coil dimensions run reasonably uniform and which have the filament axis coincident with the axis of the base and with the distance from the locating pins on the base to the filament center within distinctly close limits.

With such standardized interchangeable bulbs the headlamp could be built without any focusing adjustment, but with the bayonet socket rigidly set at the factory to give the correct light distribution with the standardized interchangeable bulbs. This would obviate any skilled adjusting by the car owner when replacing bulbs and would insure good results in lighting regardless of the skill of the owner.

(Fig. 21 shows a base construction and optical jig with which interchangeable bulbs can be produced.)

To secure the best results in lighting and at the same time

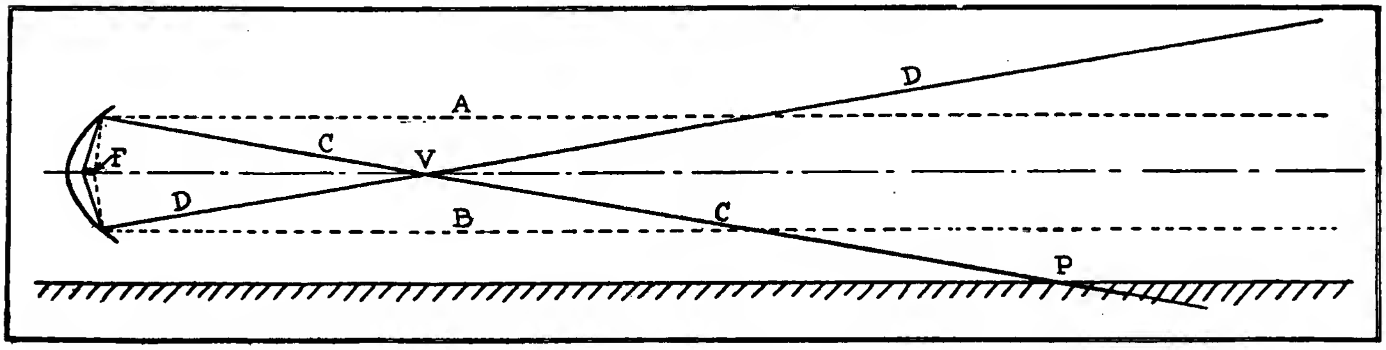

Fig. 19, Rays from part of filament at focus point F reflected parallel, rays from behind F cast D, D the glaring light, and C, C on road avoid glare it is necessary that the lamps not only give the proper distribution but also that they be properly pointed. Bulbs having their filament to one side of the axis of the base will change the direction of the beam of light and require repointing of the lamps. This will either require bending of the lamp brackets or using means especially provided for the purpose. Car makers would do well to devote some attention to this point. If interchangeable lamp bulbs were available the lamp once pointed correctly would never have to be adjusted again unless deranged through accident.

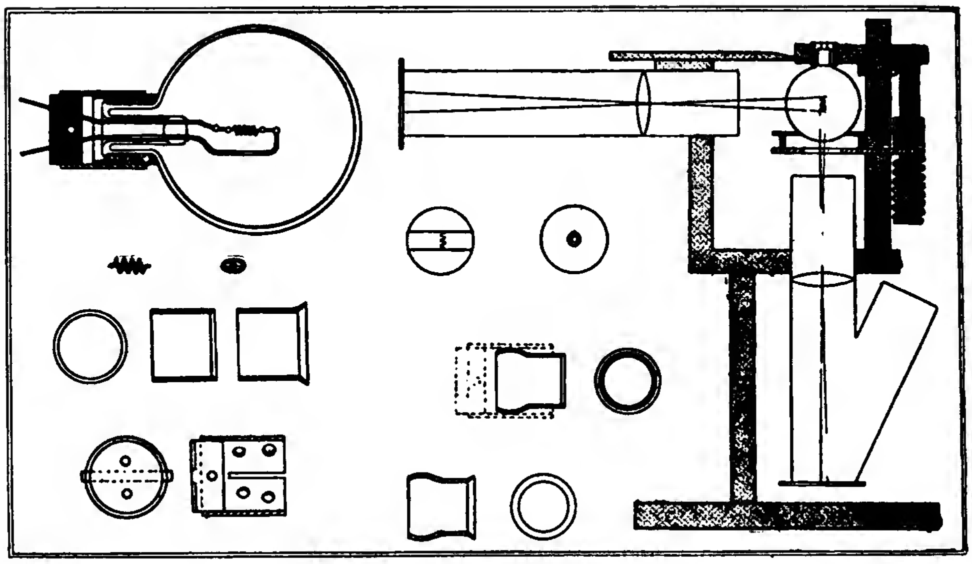

Fig. 21, Device for testing location of filament in bulb

Mounting Height

Other things being equal, the lamps should be mounted as high as possible consistent with avoiding glare. The higher the lamps are the more nearly normal do the rays strike the roadway and the smaller the difference between the vertical and the horizontal illumination, and the less exaggerated are the shadows of projections on the road surface. High mounting requires a greater vertical spread of beam to properly light the road and therefore to secure the best results the lamp and filament dimensions will have to be chosen to suit the mounting height.

I venture to say that the reason why some high priced cars made to-day have low mounted lamps is because the experimenters found that with the particular type of lamps in their possession they secured better results with low than with high mountings. But a properly designed lamp mounted high will give better all around results than any lamp mounted low. I believe that a height of 3½ ft. to the center of a lamp having a 9 in. or smaller reflector is about the highest that can be used where the beam is kept below 3½ ft. beyond 75 ft. from the car.

It needs little argument to show the advantage that would accrue to the automobile public through having uniform lighting regulations over the whole country. The automobilist is essentially a traveler and in the course of a season he is liable to come within the jurisdiction of many different authorities. The annoyance caused by having to comply with many diverse lighting regulations during these travels can easily be appreciated.

There is one system of legislation which is the best. The essential requirements of lighting regulation are the same everywhere and can therefore be met by a single set of regulations. The first great requirement in lighting regulation is to insure a maximum of safety to all parties concerned. The second is to reduce any annoyance or nuisance that may be connected with lighting to the smallest degree consistent with the meeting of safety requirements. The third requirement is that the comfort, convenience and pleasure of the automobilists should be insured in the highest degree consistent with meeting conditions one and two.

A system of regulation which best meets all three of these demands is the best system possible and should be adopted uniformly everywhere. Lighting regulations should be as simple as possible consistent with attaining the desired results. They should be couched in such terms that they can be readily understood by people of moderate intelligence and education, and in such a manner that it is easy to ascertain with precision whether they are violated.

The requirement that no strong beams of light be projected from the lamps above a level of 3½ ft. beyond 75 ft. from the car and placing no limit on the intensity which may be used below this height is a step in the right direction, and this regulation is coming into wider and wider use, which speaks well for the intelligence of the officials who have adopted it.

This regulation fulfills part of the three essential requirements but only a part. The easiest way to comply with this regulation is perhaps to greatly cut down the light and drive with an insufficient illumination. This does not meet with the requirements of safety as pointed out earlier in the paper. An addition should be made to the regulations which will specify a certain minimum of illumination that will promote the interests of safety. This should specify that the lamps throw an illumination of 0.025 ft. candles measured on the surface of a level road 200 ft. in front of the car. Also normal to a line from the nearest lamp the illumination should measure 0.1 ft. candle 10 ft. to the front and 10 ft. to the side. This latter requirement is easily met if improper attachments are avoided.

Appended to the regulations should be some recommendations as to what constitutes good lighting, for the purpose of disseminating knowledge of good lighting to the public that would be difficult to reach otherwise. In this could be briefly embodied the statements that uniformity of the illumination on the road surface is desirable; that patches of excessive brightness are undesirable; that a large area of illuminated surface promotes efficiency of vision as well as safety; that strong diffused or scattered light above the level of the lamps even though insufficient to cause glare makes driving in a fog and snow storm dangerous.

Form for Legislation

All motor vehicles capable of traveling 20 m.p.h. shall be equipped with two headlights adjusted so as to project a beam of light on a level road surface covering at least a length of the road between a point 25 ft. in front of the car and a point 200 ft. in front of the car, with an illumination that shall measure on the horizontal surface of the road at every place on the straight line joining these two points at least 0.025 ft. candles.

Also the illumination measured anywhere between the road surface and 3 ft. above it and normal to the rays from the lamps, over a point 10 ft. in front of the car and 10 ft. to either side of the center line of the car shall not be less than 0.1 ft. candle.

Further, no headlight on motor vehicles shall emit illumination measuring over 1000 apparent candlepower when measured from any point above 3½ ft. from the surface of a level road and over 75 ft. in front of the car.

South's Profits $10,000,000,000—Car Sales Gain

Rapid Agricultural and Industrial Progress of This Great Section Forecasts Opening of Enlarged Market for Automobile, Truck and Accessory Manufacturers

AT the very door of the bulk of the American automobile factories lies a great consuming territory which holds immense possibilities for the sales organizations of the various concerns. It is the South, with an area of one-third of the total area of the United States, and a population of about 35,000,000. The people of this rich region have drawn $10,000,000,000 of wealth from the rich coffers of their land. This money demands an outlet through the buying of all the necessaries and luxuries the country can supply. Of this sum, $1,000,000,000 comes from the cotton crop—$720,000,000 from the lint and the balance from the products of the seed.

The close of the year found spot cotton future contracts 4½ cents higher than one year previous, or a minimum gain of $25 per bale. Some are predicting 15-cent cotton by spring and 20-cent by Jan. 1, 1917.

King Cotton's Rivals

The war has taught the Southern farmer a great lesson, for it is no longer a one-crop land. During the past year the doctrine of crop diversification has spread to the four corners of Dixie. In evidence of her emancipation from the slavery of cotton there is the significant fact that the value of the grain crop produced by the South last year was $1,330,000,000, which is $100,000,000 in excess of the value of the most profitable cotton crop ever gathered.

The South produces 88 per cent of the total tobacco crop; 28,000,000,000 ft. of the total of 31,000,000,000 ft. of lumber manufactured in the United States last year came from the South; she produces 75 per cent of the coking coal; 41 per cent of the zinc; 42 per cent of the lead; 80 per cent of the phosphate, and produces fifty-five of the fifty-seven useful minerals mined in the United States.

The New South is a growth of a scant fifty years out of the ruins of war, while the stable institutions of New England have thriven undisturbed for centuries. Comparing the two sections, the people of the South had a few weeks ago on deposit in national banks alone $735,561,874. New England had demand deposits of $484,654,630; the South, $586,155,168. New England had time deposits of $73,175,851; the South, $149,406,705.

A Rapid Growth

Commercially, industrially and agriculturally, the South has grown faster during the last decade than any other section of the country. The population of the South in 1910 was about 30,510,000, and during the past five years population has increased at the rate of sixteen per cent. Outside of the main centers of density, where there is a natural growth of large proportions, regardless of accretions from the outside, no other section of the United States has shown a larger growth during the period named.

With no design or inspired relation, news articles are appearing in the daily press singularly consistent and of one note, in their relation, of a healthy activity and industrial condition over the Southern States.

This year, as a result of their labors, the people of Dixie have more wealth than they ever had at the close of any year. The money constitutes a factor that cannot be neglected by the sales campaigns of the automobile industry. There are few automobile factories in the South. Alabama, Arkansas, Florida and South Carolina have none. Kentucky, Tennessee and Texas have three each, while Louisiana, Virginia, Georgia and North Carolina each have one automobile factory within their borders. They cannot supply the demand.

Many New Dealers

That the factories are beginning to awaken to the possibilities in the South is shown by the fact that the manufacturers who have no representatives in this territory are sending traveling men to the big distributing centers to establish an office or branch, or to make contracts with a new dealer or distributor.

A comprehensive review of the activities of seven of the Southern states, Alabama, Florida, Georgia, Kentucky, Mississippi, Louisiana and Tennessee, forcibly brings out the growing industrial importance of the South.

South Grows 60 Per Cent of World's Cotton Crop

OF course cotton is the great staple of the South, which raises about 60 per cent of the 22,000,000 bales constituting the annual crop of the world, the contribution of the United States to this total being normally 15,500,000 bales per year. The 1913-1914 crop was 14,000,000 bales, and the 1914-1915 total was approximately 16,500,000.

The seven States, Alabama, Florida, Georgia, Kentucky, Mississippi, Louisiana and Tennessee, produce nearly 5,000,000 bales per year, with a total valuation of over $266,000,000. As shown in the accompanying tabulation, compiled from the most recent Government ginner reports, the bulk of this crop is upland cotton bales, the total being 4,424,475, as compared with only 84,769 bales of sea island cotton, which is largely used for automobile tire fabric, and 294,472 linter's bales. The value of the upland cotton is $248,876,718.75, that of the sea island $8,264,977.50 and the linter's bales are worth $9,010,843.20.

Cottonseed Products Important

Besides the cotton itself, these States produce 1,228,688 tons of cottonseed products, which sells at an average price to the cottonseed oil mills of $37.50 per ton, or a total of $46,075,800. Cottonseed oil crude obtained by the mills totals 1,150,000 bbl., of 50 gal. each, other products being cottonseed cake, meal and hulls.

The upland cotton is used for yarn, sheeting, toweling, thread, etc. Sea island cotton is useful for tire fabric and covers, fine thread, lace curtains and underwear, filling for silk ribbon and mail sack duck. Linter's is employed in gun cotton, nitro-cellulose, batting, wadding, mattress stuffing, carpet lining, mixing with shoddy, etc.

Cottonseed oil is used for insulating material, cosmetics, cooking and salad oil, oleomargarine, soap, roof composition, nitroglycerin, linoleum, cheap paint base, etc. The cake and meal are utilized in bread and cake and as feed for cattle, horses, mules, swine and sheep, and the hulls for feed, fertilizer and bran. Thus many fields of usefulness are filled and waste is minimized.

Georgia Leads in Cotton

Of the seven States mentioned, Georgia is credited with the largest cotton crop, according to recent statistics, producing 1,865,624 bales of upland, 56,722 bales of sea island and 118,000 bales of linter's, a total of 2,040,346, or more than any two of the other States combined. It produces two-thirds of the total crop of sea island of the group, 56,722 bales, Florida, with 28,047, being the only other producer of this variety.

Alabama ranks second of the seven States in total output, its 1,073,666 bales being made up of 1,012,966 bales of upland and only 60,700 bales of linter's.

Mississippi is a close third, with a crop of 958,814 bales, consisting of 898,414 bales of upland and 60,400 bales of linter's.

The Other States

Louisiana's 354,530 bales give that State fourth place, its upland being 333,908 bales and its linter's only 20,622, or much less than Tennessee's linter's crop. Although this was 32,250 bales, Tennessee's total was only 318,775, including the 286,525 bales of upland, ranking the State fifth of the group. Florida is sixth with only 57,585 bales, of which 28,047 are sea island, or more than the 27,038 bales of upland. Kentucky's crop of cotton is so insignificant that it is classed with other States than those comprising the rest of the group.

Southern States Rank High as Lumber Producers

STANDING out prominently among the resources of the South is its contribution to the lumber-consuming world. The South may be said to have three leading industries—lumber, cotton and steel. Of the three lumber is second only to cotton in the matter of dollars and cents. Ranking high among the lumber-producing sections of the United States, being a locality in which conservation of timber, perhaps, has not been adhered to more than in other regions, but by reason of a vast visible supply, standing well near the top of the ranks of future production, the South to-day is contributing a lion's share of the aggregate footage of lumber consumed in the Central, Southern and Eastern States, as well as sending millions of feet overseas every year.

Supply Is Abundant

The foregoing being true, it is not to be wondered at that advocates of the Greater South point with pride to its vast buying power in the commercial world. While it is true that in the river sections of the Southern States difficulties arise which must be considered when comparing the natural advantages of other sections, nevertheless, the South, taken as a whole, must attribute much of its financial showing to the fact that the activity in the lumber industry is at its height. There is a visible supply of timber in the South to last many years yet, if proper conservation is practiced, and with the Federal Government co-operating with timber owners, teaching them how to take from the forest, it seems likely that the people south of the Ohio River will not see the forests depleted for several generations.

Probably the South is more prolific of wood varieties than any other section of the United States. Two of the more common are yellow pine and cypress. Of the yellow pine there are two kinds—long and short leaf, the distinction between them being that the former has greater tensile strength than the latter by reason of its longer fibers. Yellow pine goes into the construction of building and manufactured articles where strength is a factor. It is harder and more durable.

Much Yellow Pine

Yellow pine of both grades go into building construction in large quantities. Certain grades go into the manufacture of boxes. Cypress found along the Gulf of Mexico and the lower Mississippi is used for nearly every purpose. Being known as "the wood eternal" it comes in as a building material in large quantities and by a burning and scouring process finds a place high in the estimation of users of interior finish, since the grain is thereby given in relief.

Kentucky and parts of Tennessee are in the hardwood region of the South. Red and white oak are found there in large quantity and as to their uses, one has but to look on every side to find them. Poplar and cotton, as well as sycamore are used considerably in interior finish, boxes and for pattern making to some extent.

The Atlantic States have another grade of pine, known as North Carolina pine, which is quite similar to long-leaf yellow pine, while Georgia has a species all her own, very hard and finding a place in all the uses to which long-leaf yellow pine generally is put. Some sections of the southeast produce walnut and other fine finishing woods, but the supply of these is more or less limited.

The consensus of opinion at the present time, according to several leading figures in the lumber industry of the South who are in a position to know, is that the lumber industry is on the eve of a period of prosperity, the equal of which has not been approximated in several years. Granting that this is true, other lines of business should prosper. The man who sells automobiles should find fertile fields for his selling campaign during the coming year. True, the sections along the Mississippi have suffered from floods, but that is no unusual thing and this year's inundation has been less severe than on several other occasions.

After a period of depression extending over the last year and a half, building activity has taken on a new impetus and in consequence new mills, bigger production plans and greater selling campaigns in the lumber industry of the South are the order of procedure. The good showing of the early part of 1914 was robbed to offset a declining market after the first

MORE IDEAS ON BODIES—BEAUTY AND COMFORT SHOULD GO HAND IN HAND—THE CASE FOR MAGNETO IGNITION

Efficiency, Beauty and Comfort the Three Ideals

By Charles H. Tuft

Daniels Motor Car Company

IN Mr. Schipper's article on Body Discomfort in THE AUTOMOBILE for Feb. 3, I believe Mr. Schipper has summed up the situation by his statement, "It is recognized that it is impossible to turn out the bodies of stock cars in the same manner as a tailor fitting suits of clothing.

Thinks Comfort Not Forgotten

I do not think that in the race after beauty of exterior, the designer lost sight of the comfort of the interior. I am sure that the majority of designers have kept this matter in mind. That some have been more successful in their efforts than others, goes without saying. There are, as the article in question states, "a multitude of things that go to make a car comfortable." As a rule, the layout of the chassis governs. The steering gear must be mounted on the frame at a place very often determined by the location of the spring links, engine legs, starter, generator, magneto or water pump, etc.

Cylinders of V-type, multiple-cylinder motors, the tops of which overhang near the frame, largely determine the position and angle of the steering gear. The unit power plant largely determines the location of pedals, hand brake and gearshift levers. Pedals and hand levers may be so designed as to make them accessible and convenient for use, but the fact remains that their fulcrums are fixed by the location of the power plant and that their efficiency to a certain extent controls their design.

Comfort Should Follow Beauty

It is no more than natural that the mechanical features and performance of a car should determine its popularity and success. Of what advantage would the most handsome and comfortable body be were the chassis faulty? Who would be satisfied with a beautiful exterior and comfortable interior, should his car lack the power and speed to take him where he wanted to go and come?

Comfort, however, should be the very next consideration after efficiency and beauty, for were it a choice between beauty and comfort in a car after its efficiency were assured, I believe the public would demand the beauty. An owner takes more or less pride in his car, and if he is assured of its beauty and gracefulness of lines, in the eyes of others, minor discomforts, if such he may have, are more than made up for. I do not believe there are many cars of later design and average price that are uncomfortable, in the real sense of the word, to the driver. There is no doubt that there are some that are inconvenient of entrance to the driver's seat, but the buyer has demanded fore doors, the center control and the individual front seat, and these have all added more or less to his inconvenience in entering and leaving the driver's seat.

A few cars have been made with adjustable front seats and sliding steering wheels, but the majority of manufacturers have encountered no public demand for a radical change in the driver's compartment. Cars have been made in which the driver has been given the extra inch or two of the surplus space which Mr. Schipper speaks of in the tonneau, with the result that the driver uses a cushion at his back and extension pads on his pedals.

I do not believe it possible to standardize any set of dimensions pertaining to the driver's seat and the location of the various controls. There are too many variables that enter into the matter. If 9 in. were accepted as the proper distance from the bottom of the steering wheel to the top of the cushion, a thick cushion with light springs and plenty of hair would allow the driver to sink 3 or 4 in. and the wheel is then too high. If 19 in. were accepted as the proper dimensions from the pedal pads to the front of the front seat it would depend altogether on the depth of the cushion (the distance from the front seat to the upholstering of the back), whether the pedals can be operated or not. The driver must have his seat "back him up" when he applies his pedal or compresses his clutch spring. He also must apply his emergency brake, in emergency, with a pull from the shoulder and a straight arm. To do this he must necessarily lean for his lever, and in this case the pedals, both pushed down, must afford the support to pull against. A great deal of the driver's weariness comes from the friction between his back and the upholstering, due to the workings of the springs in the seat cushions. Thick soft cushions, especially, have this tendency. One would tire very easily in a Turkish rocker were he continually bouncing up and down. The only way to overcome this is by having the back upholstering move with the seat, and I understand that patents have been taken out covering this form of seat construction.

Individual Tastes Differ

The writer was connected with one concern that specialized in custom-made cars and hardly two cars ever went out alike, in regard to the location of the steering wheels, pedals, levers and location and height of the front seats. Every customer wished a change of some respect made. Some wanted to sit on the floor, others wanted to sit up in the air. Some would want the steering wheel up against their bodies, others wanted to drive with the wheel at arm's length. We had a hundred and one different steering column brackets until we adopted the ball joint universal bracket similar to the Minerva. Pedals were made in numerous lengths and hand levers bent into every conceivable shape.

Must Consider Human Limitations

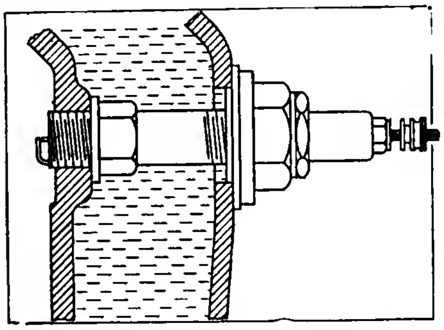
I am a thorough believer in standardization wherever possible, but as long as human beings go on varying in stature, as they have a habit of doing, I do not believe that any standards for comfort that may be adopted will meet with the approval that would be expected.

To Avoid Plug Trouble in Racing Engines

By J. E. Schipper

ALTHOUGH they were nearly all able to overcome the difficulty as the season wore on, at the start of the racing program of 1915 the major motor trouble was the difficulty of obtaining spark plugs that would stand up under the punishing conditions of high temperature prevailing in modern engines of high efficiency.

It appeared, afterwards, that the temperature was the chief cause of the trouble, and that those engines in which the spark plug was in a good position for cooling were the easiest to equip with plugs of sufficient durability.



The accompanying sketch shows an idea for providing the plug with a maximum of cooling. It is suggested that the plug boss be cast in the cylinder wall itself, instead of forming a lug connecting the inner cylinder wall with the water jacket, and that the plug body be screwed directly into the cylinder. To allow this plug body to be water-cooled direct, it would need to be longer than usual, and it would, of course, have to be put in before the water. When the plug was screwed home with a tube spanner, a nut with a soft gasket would seal the orifice in the water jacket wall.

Obviously, a plug inserted in this way, having a special, long body to suit the design of the engine, could not be changed except by first letting out the water. To combat this it is suggested that the insulator might be detachable. There are some obvious difficulties, in the details of the plug, but it seems that the efficiency of the cooling could scarcely be bettered and the idea is one that might be worth elaboration.

The Case for the Magneto

By N. J. Hart

THERE is a very distinct advantage in having an increasingly hot spark as the engine speed increases, because such a hot spark has the property of being able to clear fouled plugs and to keep clean ones from fouling up.

There are magnetos that are capable of maintaining perfect ignition at lowest possible engine speeds under all conditions. In fact, so efficient are these instruments that they will furnish absolutely perfect firing to engines revolving so slowly that not enough energy is stored up in the rim of the flywheel to carry the pistons over the next following compression point, and if it were not for the momentum of the rolling mass of the car pushing the engine over the engine would stop.

The storage battery was discarded for ignition purposes immediately the magneto was brought to its present state of perfection because of the fact that the ordinary driver could get the very best possible effort out of his engine when magneto-equipped for the reason that the current and voltage increase and decrease with the speed of the engine. This had the much desired effect of doing away with the necessity of pulling and hauling the advance and retard mechanism at every change in road condition or speed. Drivers had some comfort then. Much manipulation of the battery-ignition advance lever is absolutely necessary if one is to get any kind of power out of the engine.

Let us face the truth. Battery ignition systems cost less than magnetos and this is the prime and only cause of the adoption of methods abandoned long ago in Europe as unsatisfactory. The battery is necessary on a modern car to supply current for lighting and for starting the engine and when used for ignition purposes does not give the ideal spark for starting which is so much boasted about by the supporters of this system and for the following reason: When the starting switch is operated there is a terrific "inrush" of current into the armature of the starting motor and as the capacity of the battery generally supplied is limited first by weight, then by size, and last but not least, by cost, there occurs an immediate drop in voltage of at least twenty-five per cent, and this drop is much greater in cold weather. Coils to operate successfully must be wound for the voltages on which they are intended to work and it is therefore a fallacy to imagine that a fat spark when starting is at all possible in the face of the drop in voltage at the battery terminals when starting motor is called into action.

Battery Ill Kept

Another point to be considered is the following: The storage battery in the hands of the novice is rarely kept in even a semblance of good condition and as the battery is the "weakest link" in the most vital part of the car, it seems to me to be like "placing too many eggs in one basket."

In a great measure the carbonizing of the engine and deterioration of the exhaust valves can be laid to the door of the weak and inefficient ignition and not to bad gasoline or cylinder oil as claimed.

Misleading Switches

Another point is that the switches of the battery system have had two points indicated on their faces, the word "Bat" at the starting point and "Mag" at the running point. People have been under the impression that they have been buying magneto-equipped cars and that the word "Mag" signified magneto, when as a matter of fact, none of these cars equipped with these switches had even a place on the engine where a magneto of any kind could be installed. Even if a magneto were installed it could not be operated *with that kind of a switch* in the circuit.

RENE THOMAS, winner of the 1914 *Indianapolis race, who will drive a Peugeot car in all the leading American track races during the coming season. Thomas, who is free from military obligations in Europe, has made arrangements with the Indianapolis Motor Speedway to rebuild one of their Peugeot racing cars and will make his first appearance in the* 300*-mile race on May* 30. *It is expected that Thomas will sail from France about the middle of March and will be in Indianapolis on April* 1.

The Rostrum

How a Gear Pump Operates

IN THE AUTOMOBILE for Feb. 24, a description of the action of the gear pump was given which was incorrect, owing to the inversion of the intake and exhaust sides. The diagram shows the true action which is as follows:

When the pump is stationary it is full of oil and all the small spaces between the teeth of the gears are filled likewise. Regarding those teeth which are on the outer edges furthest from the center of the pump, it is easy to see that the small quantities of oil between the teeth are shut in by the edge of the casing. This is equivalent to saying that the space between each pair of teeth acts like a small bucket or pocket.

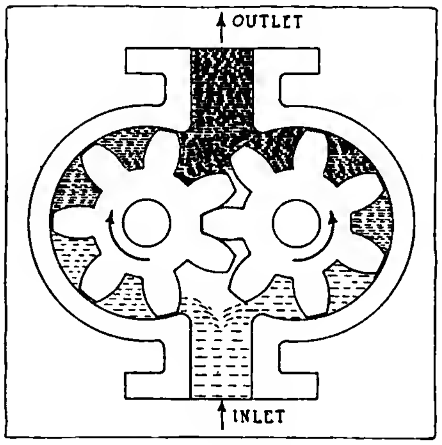


Fig. 1—Diagram of gear pump action

Now, if the gears start to turn, each tooth space as it leaves the suction side picks up its "charge" of oil and carries it round. When the point is reached where the two gears mesh together, the oil lying between the teeth is squeezed out. Thus as each successive pair of teeth meets, the effect upon the oil is the same as the downstroke of a minute plunger pump. Normally the teeth spaces are kept filled with oil and every time the teeth meet, the oil is expelled by the other tooth filling the gap.

The limit of pressure which a gear pump can create is determined by the relative areas of the teeth and of the clearance space surrounding the gears. The oil that is thrown out on the discharge side can leak back to the intake side by flowing across the faces of the gears. The amount of oil discharged varies directly with the width of the teeth, thus if two pumps are of the same size, save that one has double the width of tooth, then the larger should pump twice the quantity of oil per minute that the other will do at the same speed. This means that by making the gears wide we can create a very great pressure; indeed, there is practically no limit to it.

Lauds Studebaker Service

Editor THE AUTOMOBILE:—In the last issue of your paper I noticed a very good article entitled "Trend and Possibilities of Automobile Design," and my attention was especially attracted to the latter part of this article regarding the cost of maintaining automobiles. It seems to me, as a new owner and operator, that the different automobile companies should aim to operate their mechanical departments so as to give cheerful service and service that is not only good, but that which is honest and reasonably priced. In other words keep the customer so well satisfied with his car that he will be a booster instead of a knocker.

The scheme of the Studebaker people is an excellent one and while it does not go far enough—the first six months' use being the best life of the car—it is the right spirit for the manufacturer to have toward the operators and cannot help but make them satisfied customers. The typewriter folks keep their machines in repair for a year and I guess the automobile people are coming to the year themselves, gradually creeping up to it. I believe that if the auto folks would offer a year's upkeep of their machines with the price of the machine the increased sale of that particular machine would soon indicate very clearly the worth of the offer. I know people who are ten times more able to own a machine than I am, but who do not own one because of the excessive charges for repairs and maintenance of the machines. I know a former operator of a Ford who found the cost of keeping the machine more than he had been led to believe it would be, and now preaches the doctrine of hiring. He says you can afford to hire a machine for an occasional ride and rid yourself of owners' troubles and have a free mind. He, like thousands of others, was robbed by the repair folk. I think this form of robbery is doing more harm to the industry than even faults of the machines.

Your paper seems to be going after such practices as these and I hope you will keep up the good work and educate the manufacturers up to the idea that they must satisfy the customer if they expect to continue in the business. W. M.

Washington, D. C.

Prolonging the Life of Automobile Tires

Editor THE AUTOMOBILE:—From time to time various schemes have been suggested for equalizing the wear on tires, most of them aiming apparently to have the tires all wear out at the same time, which, to most of us not blessed with unlimited money is a calamity rather than a saving.

A plan which the writer has tried out very successfully and which he has not seen advocated elsewhere is here given. Assuming the average car with four tires on the wheels in various stages of wear and one new one as a spare, take off the right rear tire and carry it as a spare, replacing it with the new tire. Run the car 1000 miles and then move this tire to the left rear wheel, putting a new tire on the right rear. At the end of the next 1000 miles move the left rear to the left front, the right rear to the left rear and put another new tire on the right rear. After 1000 miles more repeat the process, keeping the tires moving from wheel to wheel at each 1000 miles, moving them around the car in clockwise direction. There are a number of advantages in this which are not apparent at first thought. The rear wheels naturally are the hardest on tires and of these the right rear will generally get more wear than the left due to the fact that the left usually has the better part of the road to travel on. Therefore the new tire, which is best able to withstand the wear is put on the right rear each time. When it is moved to the left rear the direction of wear is reversed. This is beneficial to the tire and is of advantage on a non-skid tire as the gripping portions presented to the road are the opposite of those we

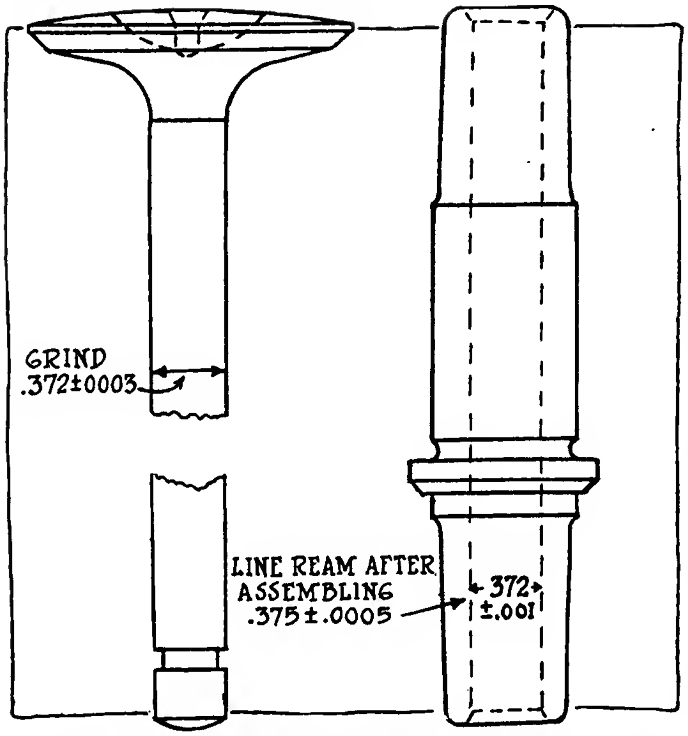

Fig. 2—Details of Continental 7-H model motor valve and valve stem guide, illustrating clearance

ran on the other wheel. To those who use reliners it may be said that the time to insert the reliner is when the tire is moved to the front wheel after running 2000 miles on the rear wheels.

The writer has tried this out on several of his friends and has yet to see a car with tires adequate to its weight which has not given greatly increased mileage per tire, in every case the tires running over the 4000 miles necessary to complete the cycle. On one car on which the owner formerly considered himself lucky if he got 2500 miles from a tire, the tires now give better than 4000 miles. To get the best results non-skid tires should be used and reliners will give additional mileage when the tires are moved up to the front wheels.

The writer's experience with reliners has been unsatisfactory when used on rear wheels or in new tires and he does not believe they should be so used.

If after a season's trial it is found that the cars are averaging well over 4000 miles (on one car on which this plan has been tried out they have averaged over 6000) the change can be made at 1100, 1200 or more miles—the whole object of the scheme being to get the utmost of wear from each tire, to have it about completely worn out by the time it has made a circuit of the four wheels and to have the expense for tire renewals come regularly and one at a time instead of irregularly and sometimes in bunches.

While on this subject why not give us a well worked out table showing the actual inflation pressures for tires of different sizes and under different loads, giving actual load weights and not empty car weights which plainly mean nothing when taking a seven-passenger car and a runabout with the same size tires. There is no use carrying a greater inflation than is necessary and proper for the weight the tire has to support, and, if we could get a really well worked out table of this sort, it would add to the life of the tires and to the comfort of the motorist. Most tires are either over or under inflated and either one is injurious. If such a table has ever been published it would bear repeating, especially if it gave bona fide pressures for bona fide weights under complete load. In these days of power pumps it is not necessary to allow 10 to 20 lb. for "that tired feeling" which comes from hand-pumping and this is just what many of the tire companies do in their tables of recommended pressures.

Larchmont, N. Y. M. C. C.

Bright Brass Dipping Solution

Editor The Automobile:—We understand that there is an acid solution or bath used by brass workers, clock makers and others in which brass parts may be dipped and the brass will not be affected by the acid, which will, however, remove all dirt, grease and tarnish and the brass will come out of the bath bright and clean. Can you give us the formula for this acid bath and instructions for its use, advising us also whether it must be kept in lead or glass containers?

2—Will you also kindly advise us what is considered good practice in the way of clearance between valve stems and their guides? For instance, in a used motor where the stems and guides are worn, assuming the stems to have been originally 0.375 diameter, new guides are fitted, or if the guides are integral, they are reamed out oversize and bushed, and in either case the finished hole is made 1/64 undersize, or 0.359. What size then should the stems on the valve be ground to—in other words, how many thousands under 0.359 to allow proper clearance when the valves are heated up and yet make a strictly first-class job? Should exhaust valves and inlet valves both have the same stem clearance in the hole?

Larchmont, N. Y. L. Mfg. Co.

—The parts to be cleaned are first dipped into a solution of hot lye and then dipped into what is known as a bright brass dip. This is made up as follows: Two parts sulphuric acid to one part nitric acid with a tablespoonful of salt to each 3½ gal. of acid. Care must be used in mixing. Put the sulphuric acid in a jar first, then add the nitric acid. Let this stand until it stops working or fuming, then add the salt. The parts to be dipped should be dipped first into the hot lye solution and then into the acid solution. Immediately after the acid dip the parts should be rinsed in cold water and then given a second dip into the acid, and then into the cold water to rinse them off. After this they should be dipped into very hot water and thrown into sawdust to dry.

2—Practice on clearance between stems and guides is shown in the accompanying illustration, Fig. 2, which details the 7-H model Continental motor valve and valve stem guide. The dimensions apply to both intake and exhaust. It is the practice of the National Co. if a finished hole of 0.358 to 0.360 is indicated, to use a valve stem diameter of 0.355 or 0.356. This clearance would be suitable according to the National company for both inlet and exhaust. The Northway company states that the valve clearances vary between 0.0025 and 0.004, depending on the design of the exhaust port. The Buick Motor Car Co. allows a clearance of 0.0015 to 0.002 on the intake and 0.0025 to 0.003 for the exhaust.

Carbon Monoxide a Poisonous Gas

Editor The Automobile:—What are the chemical composition and the chemical and physical properties of the gas called Petromortis supposed to be deadly?

2—Are there any unusual atmospheric conditions conducive to its formation?

3—Could theoretically imperfect carburetion or ignition cause the generation of the gas?

4—Could the improper composition or condition of gasoline or lubricating oil cause the generation of the gas?

5—Is the gas liberated in such concentration that ordinary ventilation of the garage will not prevent asphyxiation?

6—Is the presence of the gas in harmful proportions in the garage detectable by the ordinary human senses?

7—Is the harmful effect of the gas immediate or might its effect be noticed a given length of time after inhalation?

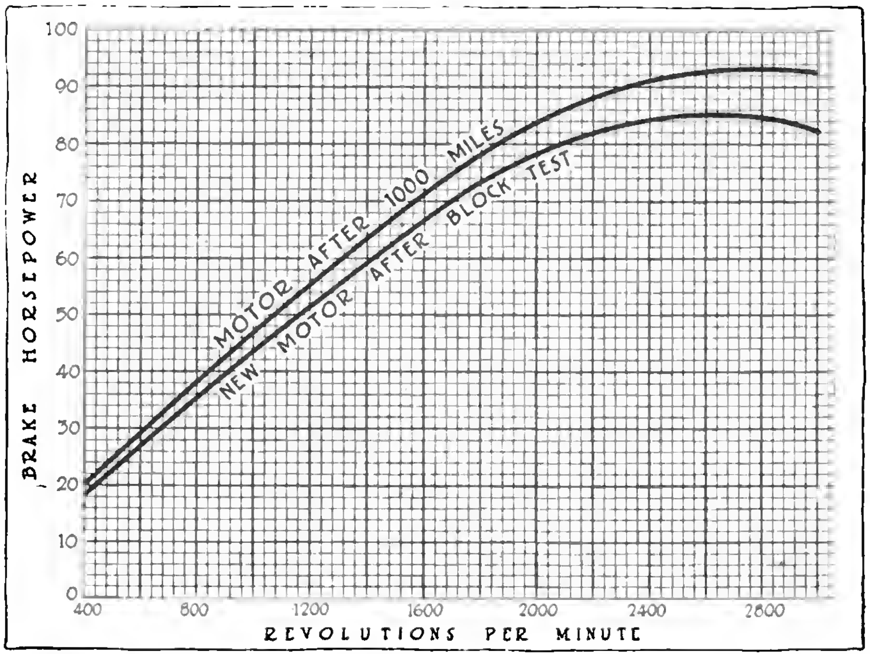

Fig. 3—Horsepower curves of Packard twin-six motor when new and after 1000 miles

8—In general does unconsciousness result so quickly that the victim could not reach the open air after realizing approaching danger?

9—Would access to open air be sufficient to relieve all harmful results in case open air was reached after discovery of the presence of the gas and its inhalation?

10—Are the physical and chemical properties of this gas well enough known so that a simple means of detecting its presence in the garage is possible even though its accidental generation could not be prevented in a practical manner? C. M. C.

Fort Canby, Wash.

—The gas which has the deadly effect is carbon monoxide. This is not only a suffocating medium but is also a poison. Carbon dioxide is a deadly medium, too, but only in that it is a non-supporter of life, although not a posion.

2—No.

3—Yes

4—Yes.

5—With very bad or incomplete combustion the carbon monoxide ingredient can be so large that it will cause bad effects even with average ventilation, but it will hardly be fatal except in an entirely enclosed room, or a room in which there is no air circulation.

6—No.

7—Headache and pain in the eyes are felt by some people in the presence of the gas, but not by all.

8—There may be no direct warning except a drowsy sensation which quickly deadens the senses of the victim.

9—Yes.

10—The stinging sensation in the eyes and headache is usually sufficient warning.

Explanation of Systems of Ignition

Editor The Automobile:—In your list of technical specifications for passenger automobiles published in the issue of The Automobile of Dec. 30, 1915, the systems of ignition are given as single, dual, double, 2 point and duplex.

Will you kindly furnish me with the correct definition of each of these terms? W. H. R.

New York City.

—Single ignition is where there is one source of current and one set of spark plugs.

Dual ignition is where there are two sources of current and one set of plugs, the systems being independent in every respect until the distributor mechanism is reached. In this point, including the distributor, high tension leads and spark plugs, the one set does for both systems.

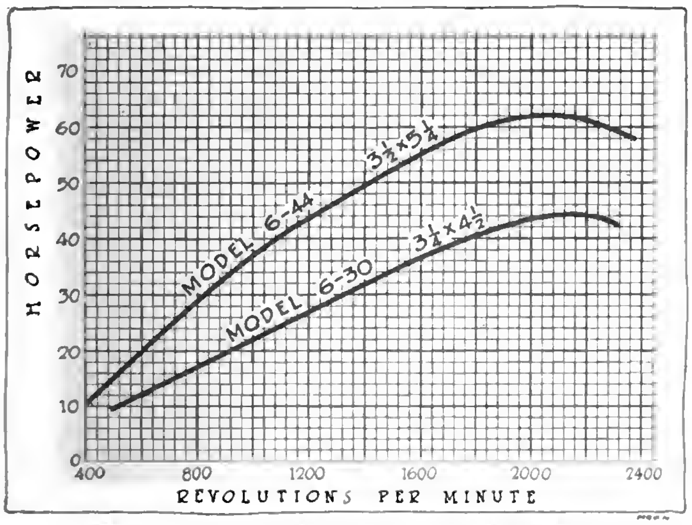

Fig. 4—Horsepower curves of two high-speed Moon motors

Double ignition employs two current sources and two entirely independent systems, either one of which may be used independently of the other. Both may be used at the same time, but perfect synchronism will not be attained unless there is some special arrangement for attaining it. The double system means that there are two absolutely independent ignition systems.

Two-point ignition is where two sparks occur in the cylinder at the same time; generally this is done by the use of a double distributor, but recently there have been series spark plugs put on the market by means of which a single spark ignition is made into a two-point system by simply connecting the plugs in series.

The duplex system is where a coil is used in a battery circuit and connected to the primary of the magneto. This gives a hot spark at low rotative speeds and is only intended as a booster current for starting. After the motor is running at normal speeds the circuit is the same as the single magneto system, the duplex cil not being in use.

Horsepower Output of the Moon Motors

Editor The Automobile:—Will you kindly publish the horsepower curve of the Moon model 6-44 and 6.30 motors?

New York City. J. E. S.

—These horsepower curves are shown in Fig. 4 and are illustrative of the typical up-to-date high-speed practice.

Horsepower Output of Packard Twin Six

Editor The Automobile:—Will you kindly give the horsepower curves of the 1916 Stearns-Knight eight and the Packard twelve? G. A. S.

Philadelphia, Pa.

—The horsepower curve of the Stearns-Knight eight is not available. That of the Packard twelve is shown in Fig. 3. It will be noted that two curves are shown of the Twin Six Packard. The lower curve represents a comparatively new motor well worked in on the dynamometer, while the other curve represents the power that it is possible to get out of a motor when well worked in by a lot of road service.

ACCESSORIES

K-P Aluminum Pistons

EACH set of K-P aluminum alloy pistons for Ford motors has a complete equipment of properly fitted rings; the pistons are of standard size and are ready to slip into the cylinders. The rings are the K-P, made by the same concern; they are of the three-piece type with all joints blocked by the solid metal of the jointless sections of other parts, and the ends are so locked that they cannot warp up and score the cylinders in case of overheating, the makers state. The pistons sell for $26 per set of four. —Keys Piston Ring, Inc., St. Louis, Mo.

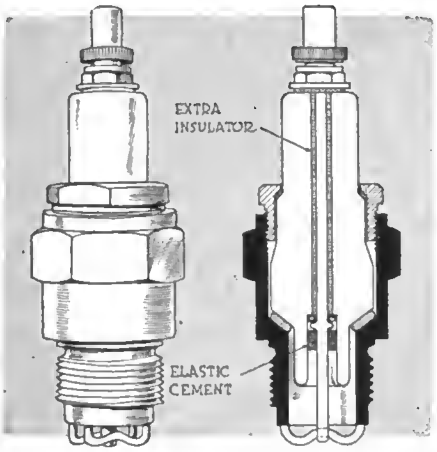
K-P aluminum pistons for Ford motors

Jumbo Spark Plugs

The Jumbo Jiant is the leader of this line, which comprises three other plugs, the Jumbo Regular, Junior and Ford Special. The Jiant is designed for the utmost durability in service on high-speed, high-compression motors as well as in all heavy-duty types. It is made in S. A. E. ½-in., metric and S. A. E. long sizes. The Regular is made in S. A. E., ½-in. and ½-in. long sizes. The Junior is for medium-speed, medium-compression motors and is made in S. A. E., ½-in. and special motorcycle sizes.

Some of the advantages claimed for the Jumbo construction, illustrated herewith, are: Terminal will fit any connection; extra insulator insures spark in case porcelain is cracked or broken; asbestos washers allow for expansion and prevent leakage; elastic cement strengthens lower part of insulator and prevents compression escaping around electrode; massive nickel-alloy points gives hottest possible spark, prevent pre-ignition at points and will not burn off; two large shell electrodes fastened at both ends cannot be bent or twisted out of place; downward slope of electrodes from points of contact allows oil to run off, thus preventing fouling.

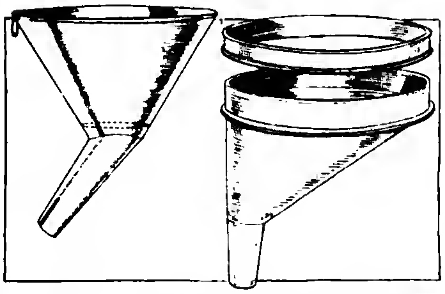
The Jumbo Jiant sells for $1.25; the Regular for $1; Junior for 75 cents and Ford Special for 75 cents.—Wales-Adamson Co., Chicago, Ill.



Jumbo spark plug, showing construction

Dover Funnel for Cadillacs

Designed especially for Cadillacs, this funnel has the spout set at an angle so that the filling of the oil reservoir in the eight-cylinder car is greatly simplified. Capacity, 1 qt.; top diameter, 6½ in; height, 7½ in; outlet, 1 in. The funnel is of heavy pressed steel, copper plated, and is fitted with brass strainers. The Kompact, the other funnel illustrated, is of the offset type, one side being vertical and directly in line with the spout, so that it is easily used in places where there is little or no room at one side. The top has a removable hoop to hold a chamois strainer, and a fine brass strainer is provided. Capacity, 4 qt.; top diameter, 9½ in.; height, 9½ in.; outlet, ⅞ in. Price, Cadillac, 50 cents; Kompact, $1.25.—Dover Stamping & Mfg. Co., Cambridge, Mass.



Two new Dover funnels. Left is especially for Cadillac cars. Right is the Kompact offset type for general purposes

Eveready Starter for Fords

The Eveready is a one-wire electric starting and lighting system for Ford cars, the motor-generator being directly connected to the crankshaft by a flexible coupling. It runs at engine speed, causing no drag on the engine and has no chains or sprockets. The starting motor acts as an auxiliary flywheel, reducing vibration and making it possible to throttle down to 3 miles per hour on high gear, according to the maker.

Besides the motor-generator, the system comprises a special 12-volt storage battery, lighting and starting switches and wiring. The battery is carried on the footboard, flat against the heelboard of the front seat.

To start the car, the spark lever is shifted to the full retard position, which sets the starter spinning. When the spark lever is advanced as the engine attains the necessary speed the dynamo automatically begins to regulate and charge the storage battery. The system is so simple that it can be installed in a few hours without drilling or making any changes in the engine or car.—American Ever Ready Works, Long Island City, N. Y.

Mounting of motor-generator used in Eveready starting and lighting system for Ford cars. A flexible coupling is used

Blackmoor Curtain Opener

A suitable bracket is attached to the door so that the storm curtain opens with the door. The bracket is adjustable to any make of car and can be quickly removed when not in use. Curtains to be used with these brackets are furnished with all makes of cars. The price for the opener is $2.50 per door.—Dayton Top Improvement Co., Dayton, Ohio.

Outlook Windshield Cleaner

In this device, an adjustable wiper for rubbing off a section of the windshield glass is mounted in a suitable bracket and can be operated easily by the driver. It is finished in black or nickel and the wiper itself is made of rubber. It lists at $1.50.—Outlook Co., Cleveland, Ohio.

Universal Radiator for Fords

In THE AUTOMOBILE for Feb. 10 it was stated that the Universal radiator for Ford cars was of heavy steel, well enameled and finished. This should have referred to the Universal hood, as the radiator is made in black enamel and nickel.

Good Lighting

WHAT good lighting really is is well explained in the S. A. E. paper which is concluded in this issue of THE AUTOMOBILE. It is a careful analysis of the *details* which affect the whole difficult subject. Mr. Clark has explained, both in exact terms of scientific units and in simple language also, what sort of a beam and what sort of general illumination is necessary in an automobile headlight to produce a safe driving light which will not exercise a dazzling effect upon other users of the road.

The fact that Mr. Clark favors a particular method of producing a lamp to suit the conditions is beside the case. The lamp he describes may be the best possible, and there may be many other means for obtaining the desired light. The important thing is that we have here a full and easily understandable definition of the things which a lamp ought to do.

The requirements once stated thus clearly, the problem of devising lamps to suit them is facilitated greatly, the problem of legislating so as properly to control lights ought to be rendered easier, and the way out from the present chaos brought within sight.

Even supposing that Mr. Clark's conclusions are capable of destructive criticism, suppose even that they were proved wrong in some respects, we still have before us the proper way to attack the problem. A proper system of gaging light and what it does is three-quarters of the battle for a sensible and simple means for obtaining the results which everyone desires.

It may be recalled that an effort to establish some sort of automobile standard of lighting was made by a German scientist in 1913 and his suggestions were given in THE AUTOMOBILE for July 17, 1913. Since then no more has been heard of the idea from that source and the professor had not worked it out to nearly as fine a point as Mr. Clark has now done.

Strengthening the Grip

THE manufacturing conditions of Europe are such at present that the whole world has to look to America for automobiles. Large parts of that world, outside Europe itself, offer wealthy and prosperous markets; ready money markets where the American manufacturer has no work to do in selling his product.

Simultaneously, the domestic demand is at least as great as the supply. It is difficult to find automobiles for shipment overseas, so urgent are the calls from domestic dealers.

The condition prevailed all last year, but it was only in the late fall that American automobile manufacturers showed signs of appreciating the facts of the case.

There is one aspect of it that is still liable to be neglected, and this is that when demand exceeds supply for any commodity, the price is raised automatically. The value of an article in ultimate terms is the price that those wanting it are prepared to pay. This means that the overseas markets which cannot get automobiles from anywhere except America are able and willing to pay handsomely for them. The foreign markets were never conditioned so advantageously to the American manufacturer, and it is safe to predict that they will remain in the present state not longer than for two years after the conclusion of the war. This gives America not less than three years and possibly a little longer to make the best of the opportunity to establish a worldwide trade on a firm and lasting basis.

Manufacturers of all kinds of goods are getting so strong a hold on South America that they will be entrenched against any recommencement of European exportation. Instead of being offensive they will in future be defensive, or, in other words, the tables have been turned in every country in the world. The proportion of America's automobiles being exported, even including all the war orders, is a vastly smaller percentage of the total output than it ought to be.

The overseas markets are not to be held without effort. Just now it is easy to sell anything to countries which are stripped of their normal European supply, but this easiness will not persist after the war. To pay the costs of warfare Europe will be forced to give far more attention to her export trade than ever before, and to retain the markets now so wide open, America must be prepared to meet competition of the keenest kind.

Court Issues Injunction Against Standard Welding

Prohibits Manufacture and Sale of Demountable Rims Held To Infringe Perlman Patent—Hoped-for Adjustment of Royalties and Damages Not Accomplished

NEW YORK CITY, March 8—An injunction was issued to-day by the U. S. district court for the Southern district of New York by which the Standard Welding Co., Cleveland, Ohio, maker of a large proportion of the demountable rims used on automobiles, is prohibited from further manufacture and sales of such rims. The injunction is the result of a suit brought by Louis Perlman, New York, against the Standard Welding Co., charging infringement of Perlman's basic patent on demountable rim construction and applies to this type of rim only.

This court action ranks second in importance to the Selden patent decision, in that it is believed to affect the manufacture of the majority of demountable rims. Stopping production of a large percentage of demountable rims will have serious consequences with many car concerns, and may require using clincher or quick-detachable types. It is impossible at this time to forecast the consequences.

Previous to the granting of the injunction conferences were held with the object of effecting a settlement by the payment of royalties and damages, but it is reported that royalties asked were too high and negotiations failed.

The court of appeals denied the Standard Welding Co.'s petition for a rehearing based on the contention that Perlman's alleged date of invention is wrong, and that his patent is invalidated by the Tillinghast patent, which is alleged to be of prior date. The petition also cites a decision by the court of appeals of the District of Columbia, alleging that it definitely limits the breadth of the claims in Perlman's patent so that they do not cover the Standard Welding construction.

A motion by the Standard Welding interests, to include in the mandate a clause in regard to the right of the district court to suspend the injunction upon sufficient cause being shown and after due notice, was also denied by the court of appeals.

The serious consequences to the automobile industry of the enforcement of the injunction may be realized when it is considered that over 700,000 of the cars to be made this year may use demountable rims and that a large percentage of the output is furnished by the Standard Welding Co.

The Standard Welding interests state that Perlman's demands are exorbitant, and that, while they are willing to pay the inventor a reasonable sum and a just royalty on future manufacture, they cannot meet the terms he names at present.

Perlman's contention is that his claims are reasonable, and that, as he has consistently maintained, he seeks an equitable, fair and honorable adjustment for all concerned.

Suit Filed in 1913

Perlman filed suit against the Standard Welding Co., Oct. 7, 1913, in the U. S. district court for the Southern district of New York, charging infringement of his demountable rim patent No. 1,052,270 issued on an application filed June 29, 1906, which was a continuation of and substitute for an application filed May 21, 1906. Perlman's idea, he said, was to patent "a wheel whose demountable rim is bodily detachable from its fixed rim and felly, means being provided for firmly and rigidly retaining the demountable rim on the fixed rim and felly while in use, such means at the same time being adapted to be manipulated for enabling ready, rapid and easy removal of the demountable rim when desired."

A decision in Perlman's favor was handed down by Judge Hunt Aug. 18, 1915, the court stating:

"Finally, Perlman's patent shows invention, completed by him in 1903. Two distinct features mark the invention: (1) The demountable rim combination with its locking means; and (2) the short-stem lug combination for clamping the tire to the demountable rim. The invention claimed was based upon a provision for a demountable rim which is loose on the wheel when applied, but is locked by locking means which may be unlocked and thereby may restore the loose condition before commencing removal. This same combination has been adopted by defendant and the same combination as disclosed and claimed in the patent in suit has been taken. Plaintiff disclosed to the defendant the patented invention before defendant began to manufacture demountable rims.

"The evidence requires the finding of infringement and the granting of an injunction and accounting in usual form."

A Decree Issued

In due time, early in September, 1915, an interlocutory decree was issued by the court in favor of Perlman, perpetually enjoining the Standard Welding Co. from further infringement of his patent and appointing a special master to determine the amount of damages.

An order was also issued at this time allowing the Standard Welding Co. to appeal to the circuit court of appeals, which was subsequently done, the decision of that court, upholding Judge Hunt in declaring the patent valid and infringed, being reported in THE AUTOMOBILE for Feb. 17, 1916.

Standard Welding May Build Under Other Patents

CLEVELAND, OHIO, March 6—General Manager J. C. Manternach of the Standard Welding Co., the only official of the company in the city at present, said he thought that Perlman would not bring an injunction suit to enforce the terms of the recent rim decision, without giving some notification of his intention to the company or its attorneys. The decision, he said, gave him the right to bring such a suit, if he so desires.

Regarding the payment of royalties on rims already manufactured under patents said to infringe those held by Perlman, it is said that this will depend somewhat on negotiations with him.

Mr. Manternach did not care to indicate what course would be taken in the future, but indicated that some of the many patents held by the company might be used in place of those which have been adjudicated in favor of Perlman. This, however, will be a matter for future decision.

Locomobile Changes Truck Name

Commercial Vehicles of Locomobile Manufacture to Be Called "Riker" in Future

BRIDGEPORT, CONN., March 7—The name of Locomobile as applied to motor trucks built by the Locomobile Co. of America, this city, has been changed to Riker, the new name being a distinct recognition of the work of Andrew L. Riker, now vice-president of the company, and who has been in charge of engineering since the four-cylinder Locomobile car was brought out in 1902. Although the name Locomobile will be discontinued as applied to trucks, the Locomobile passenger cars will continue the use of the name Locomobile as they have done in the past.

Several reasons are advanced for adopting the name Riker for the trucks of this concern. Foremost is the fact that the name Locomobile is to-day associated with expensive, luxurious automobiles, manufactured in limited quantities. This fact contrasts with the motor truck which is a vehicle of business, and which is used because of its money-earning ability. As a truck-builder, Mr. Riker's experience goes back 16 or 18 years, when he built the Riker electric delivery vehicles, some of which are still in the service of B. Altman & Co., one of New York's largest department stores, and the Gorham Company, a leading New York silversmith. After being engaged in the manufacture of electric vehicles in Brooklyn, and later in Elizabethport, N. J., Mr. Riker was engaged by the Locomobile company to develop a line of gasoline cars, and brought out the first Locomobile four-cylindered car.

Although the name of the trucks has been changed from Locomobile to Riker, there will be no changes in the line of vehicles manufactured other than natural improvements that come from time to time. The Locomobile Co. of America stands back of the product as it did before the name was changed.

National United Service Co. Takes Over Arbenz

NEW YORK CITY, March 8—The National United Service Co., with headquarters in the U. S. Rubber Building, has taken over the Arbenz Car Co., Chillicothe, Ohio. The National United Service Co. is preparing to take over four other automobile concerns and has increased its capital from $150,000 to $1,000,000. It is planned to assemble the Arbenz car, three models of trucks, 1-ton, 1½-ton and 3-ton, and an agricultural tractor in the plants to be acquired in various parts of the country.

H. F. Vortkamp, Jr., is president of the company, the other officers being A. C. Hartho, vice-president and treasurer; C. V. Neal, second vice-president; and L. T. Gresser, secretary.

Pullen, in Mercer, Wins Ascot Speedway Race

LOS ANGELES, CAL., March 5—Pullen in a Mercer won the George Washington Sweepstakes, a 100-mile race, at the opening here to-day of the new Ascot Speedway. His time was 1 hr. 30 min. and 42 sec., or 66 m.p.h.

Burman in a Peugeot finished second and Cooper in a Stutz was third. Their time was 1:32:43 and 1:32:44 1/5 respectively.

Peerless Truck Profits $2,555,773

NEW YORK CITY, March 8—The Peerless Truck and Motor Corp. reports for the year ended Dec. 31, 1915, net profits of $2,555,773, after providing for the full year's interest on the company's notes, on which there only accrued one month's interest, deducting all interest charges of subsidiary companies and creating a special reserve account of $600,000. This is equivalent to 22⅛ per cent, earned on the capital stock.

The balance sheets of the subsidiaries show current assets of $5,611,780 and current liabilities of $1,391,587, leaving working assets of $4,220,193.

Buick Elects Officers and Directors

FLINT, MICH., Feb. 29.—Officers and directors for the current year of the Buick Motor Co., are the following: Charles W. Nash, president and general manager; C. S. Mott, vice-president; T. S. Merrill, secretary; James T. Shaw, treasurer; Floyd A. Allen, assistant secretary-treasurer; L. F. Oland, comptroller.

Sparks-Withington Trebles Capital

JACKSON, MICH.—At the annual meeting of the Sparks-Withington Co. the capital stock of the company was increased from $300,000 to $1,000,000, and it was decided to double the size of the plant.

J. Walter Thompson Co. Has Jeffery Advertising

CHICAGO, ILL., March 8—The J. Walter Thompson Co. will continue to handle the advertising business of the Thomas B. Jeffery Co. In THE AUTOMOBILE for Feb. 24, it was stated otherwise but this was an error.

New Company Will Cast Car Bodies

Officials of Aluminum Castings Co. Form $100,000 Co. for Body Specialization

DETROIT, MICH., March 8—The Castaluminum Body Co. has been incorporated here with a capital stock of $100,000 to build aluminum automobile bodies. Those interested in the new concern are Charles B. Bohn, Michigan manager of the Aluminum Castings Co.; Robert F. Dyer, assistant sales manager of that company, and Wm. A. Watts, sales manager of the Pantasote Co., Windsor, Ont. As its name implies, the new concern will manufacture automobile bodies constructed of cast aluminum, though the exact plans of the new organization are withheld for the present.

It will be remembered that the Pierce Co. has used cast bodies for many years and that Cadillac has just commenced to do so for closed cars.

Pierce Plant Closed

BUFFALO, N. Y., March 4—The whole plant of the Pierce-Arrow Motor Car Co. has been closed down, owing to the strike of the machinists. This throws about 6000 men out of employment temporarily. Officials of the Pierce company state that they preferred to close the whole plant rather than to endeavor to run with the machine shop closed to the unavoidable disorganization of the factory system.

Santa Monica Gets Grand Prix and Vanderbilt

SANTA MONICA, CAL., March 8—The Grand Prix and Vanderbilt Cup races will be held on the Santa Monica course this year. The struggle for the honor of promoting the two classics has been very keen. The decision of the Motor Cups Holdings Assn., which controls both the Grand Prix and Vanderbilt cups, not to allow these for competition on speedways, paved the way for road racing associations to make a bid for the classics.

Omaha Man Sues Automobile Manufacturer

OMAHA, NEB., March 6—If the $100,000 damage suit brought for personal injuries by William Adair of North Platte, Neb., against an automobile manufacturer is won by the plaintiff, many similar suits against automobile manufacturers the country over are likely to follow. The outcome of the suit, which was brought in the district court of Pottawatomie county, Iowa, a few days ago, hinges upon the jury's decision as to the liability of a manufacturer for an accident in which its car is involved after the car has been sold to a private individual.

The petition sets forth that George Coffee of North Platte, Neb., bought a six-cylinder automobile on May 29, 1914, and that on June 10, 1914, Coffee was taking Adair from North Platte to Cheyenne, Wyo., in this car. One of the wheels broke, and the car turned over upon Adair. He sustained a fractured hip and internal injuries.

The grounds for the suit are that the manufacturing company was negligent in putting a car with defective wheels on the market. The petition sets forth that the spokes were brittle, notwithstanding the fact that the company had advertised that the woodwork was constructed of the best material on the market, and that the car was a perfectly safe vehicle for the transportation of persons on a public highway while running at a speed of 30 to 40 m.p.h.

G. M. Davis with Stewart Motor Corp.

DETROIT, March 1—George M. Davis who was manager of the Internal Gear Drive Association which he organized last year, has joined the organization of the Stewart Motor Corp., Buffalo, in the capacity of sales and advertising manager. Mr. Davis is an old timer in the automobile industry, having been advertising manager years ago of the old E. R. Thomas Motor Car Co., also assistant sales manager and advertising manager of the Pierce-Arrow Motor Car Co., both in Buffalo.

Champion Increases Output to 100,000 Spark Plugs Daily

TOLEDO, OHIO, March 2—The Champion Spark Plug Co., this city, will increase its output from 45,000 to 100,000 spark plugs per day as soon as a new six-story addition to its present quarters is finished. Work will be started on this new building during this month. And to further add to the present production, the company will build another story to its present four-story addition which was built some two years ago. When these additions are completed, it will have 60,000 more square feet of space.

San Diego Race March 5

SAN DIEGO, CAL., March 2—A 50-mile automobile race is scheduled for March 25 at the Fair Grounds in this city. The race will be under the direction of the Panama-California International Exposition. Entries have already been received from half a dozen drivers. The entrants will compete for a $2,500 cup offered by the Exposition and money prizes. The race will be run over a mile track inside the Exposition grounds.

War Truck Orders Near Finish

England Now Fully Supplied —Exports Trucks to Russia —France Fully Equipped

LONDON, ENGLAND, Feb. 18—There is every reason to believe that England now possesses such a supply of automobile trucks that no more orders will be placed in America. Absolute confirmation of this is unobtainable, for only the military authorities are in possession of the full facts, and they refuse to make any statement or to give any indication as to conditions. It is no secret, however, that there is a slackening off in the production of ordinary trucks for military purposes, and that deliveries can be made, under certain restrictions to private concerns. More frequently, however, when the English factories are told to diminish their output of army trucks they are given other military work, instead of being allowed to meet private orders.

A very significant fact, which tends to confirm the statement of England's sufficiency in the matter of trucks, is the recent sale of a number of American trucks to Russia. This sale comprises 500 trucks of the make which has given the greatest satisfaction, originally bought for service in the British army, but since transferred to Russia.

A similar tendency is observable in France, where there appears to be a sufficiency of trucks for all immediate requirements, even supposing, as is quite probable, that hard fighting with frequent movements takes place during the next few months. For some time past only spares have been coming in for the five best known American trucks used by the French, and although Velie has recently received a big order, there is every indication that France has now got as many supplies from America as she needs for some time to come.

Roto Light Delivery Truck at $695

HANNIBAL, MO., March 7—The Roto Motor Co. has been incorporated here with a capital stock of $350,000 for the manufacture of light delivery trucks. The new company was organized by N. L. Le Blond, manager of the Hannibal Wagon Co., and he expects to start the manufacture of a ½-ton model within the next sixty days.

The Hannibal Wagon Co. will pass out of existence and its plant at Collier and South Eleventh Streets will be turned over to the new concern. L. E. Jerome of Chicago is heavily interested in the Roto company and will reside here. The president will be T. A. Legris of Kankakee, Ill., a member of the Legris Brothers' Banking Co. of that city, and J. E. McNally of this city will be the vice-president.

The plans are to build at least 1500 trucks the first year. It will have a wheelbase of 112 in., with a 31 by 4 tire, a 3½-in. bore overhead-valve engine of the factory's own design and will be sold for $695, equipped with electric starting and lighting system. The car will be assembled at the plant here. A trailer also will be placed on the market.

Automobiles and Trucks To Star in Military Tournament

NEW YORK CITY, March 7—Automobiles, motor trucks and armored cars will play an important part in the military and naval tournament scheduled to be held at Sheepshead Bay during the week beginning May 20 and ending May 27.

Prizes will be offered to both manufacturers and drivers of armored cars and motor trucks of various sizes and types in endurance trials and field tests. There will be 5000 militiamen camped at the speedway and their transportation and commissary arrangements will require a wide use of both passenger cars and motor trucks of all sorts. Moreover, there are to be parades, searchlight drills, night signalling, etc., all of which will bring the motor vehicle opportunity to prove its value for military purposes.

Over 100% Rebates to Exhibitors at National Shows

NEW YORK CITY, March 6—At the regular quarterly meeting of the members of the National Automobile Chamber of Commerce, Inc., held yesterday, the show committee reported that 120 per cent will be returned to the exhibitors at New York and 102 per cent to those taking space at Chicago. This excellent showing is entirely due to increased attendance, the public paying approximately 30 per cent more than last year for admission to the shows.

The traffic department report showed that carload shipments of automobiles during February were larger than on any month in the history of the industry.

The freight car shortage is causing considerable inconvenience to the manufacturers, while the increasing difficulty of obtaining cars has been responsible for numerous delays in delivery. Many manufacturers have been obliged to utilize flat cars, while it is becoming frequent for cars to be shipped with fenders removed, so that the narrow-door box cars can be used.

About seventy-five manufacturers were represented at the meeting. T. C. Leland, vice-president of the chamber, presided, as Col. Chas. Clifton is still in Florida.

Chevrolet Earns $1,653,686

Cash on Hand $5,377,079—Predict $6,000,000 Profits for 1916—Materials Scarce

New York City, March 7.—Earnings of $1,128,590 are reported by the Chevrolet Motor Co., for the 4½ months ended December 31, 1915, after deducting expenses. To this total was added $525,096 from other sources, making the aggregate revenue $1,653,686.

Cash on hand on Dec. 31 amounted to $4,192,968 and the statement issued yesterday showed that this has been increased to $5,377,079 by March 3, a gain of nearly 28 per cent in slightly more than 2 months.

W. C. Durant, president of the company, in his statement to the stockholders said: "While materials at the moment are difficult to obtain and prices are considerably higher in some instances the reduction in overhead expenses due to increased volume of product enables us to show a reduction in cost as compared to the 4½ months covered by the report.

"Due to abnormal conditions, as a matter of protection, we are carrying extremely large inventories, fortifying ourselves, to take care of contracts and orders representing a value in excess of $26,000,000 now upon our books for delivery within the next 5 months. The operating profits of the Chevrolet companies for the year ended Dec. 31, 1916, should approximate $6,000,000, to which will be added the income from other sources."

Detailed figures of the income account follow:

Net earnings from operations, after deducting cost of manufacture and expenses of advertising, selling, administration, taxes, etc.		$1,128,590
Other income:		
Cash discounts on goods purchased	$64,129	
Interest earned........	24,434	
Dividends received.....	2,742	
Profit-sale of securities	448,323	
Miscellaneous revenue..	15,857	
	$555,488	
Deduct:		
Expenses incidental to organization	30,392	
		525,096
Net income for period (4½ months)		$1,653.686

The Chevrolet company produced in the 4½-month period just 11,888 cars through its five plants in New York City, Tarrytown and Flint. The Oshawa, Ont., and St. Louis plants, which were recently started, have turned out comparatively few cars, their output not being included in the above figures. In February, President W. C. Durant announced that within the next six months the daily output of the company was to be doubled, at the rate of 230 cars a day and stepped up monthly until the plants are producing 460 daily in August.

C. M. Hall Lamp Co. Doubles Floor Space

Detroit, Mich., March 6—Additions were completed recently to the plant of the C. M. Hall Lamp Co., which provide about 15,000 sq. ft. of additional floor space for manufacturing purpose. The company has also increased its capital stock from $150,000 to $300,000 a few days ago. At present about 230 men are on the pay roll. They work 14 hours a day during four days. Wednesday and Saturday no overtime is scheduled.

During January and February the increase in business was between 65 and 70 per cent, as compared with the first two months of 1915. Orders now on hand are sufficient to keep the plant in full operation till 1917. This may also be said about the needed materials on hand, which is even sufficient for a large per centage of the 1917 output. The company has large contract orders with the Packard, Hudson, Studebaker, and other automobile manufacturing concerns. Their value is in excess of $1,000,000 of gross business.

The capital stock of the company has been placed on a 2½ per cent monthly dividend basis. Previous to the increase of the capital, the stock had been for some time on a 30 per cent yearly basis.

United Garage Assn. Appoints Officers

Albany, N. Y., March 2—William M. Haradon, New York, was re-elected president of the United Garage Associations of New York, Inc., at the annual meeting and convention held here yesterday and to-day. All other officers also were re-elected, these including vice-president John Van Benschoten, Poughkeepsie and treasurer Edward W. Leahy, Albany. George F. Kaiser was appointed secretary for a term of three years. Among other things, the meeting adopted resolutions deprecating the action of the gasoline refiners in permitting a chaotic condition with regard to prices; approved the passage of a lien law similar to that now in force in New Jersey; approved the introduction and passage of a Fraud on Garage Keepers measure; changed the date of the annual meeting from the first Wednesday in March to the first Wednesday in January, during the New York show; changed the place of the annual meeting from Albany to New York City; revised the By-Laws. The meeting made plain that the association soon will take an active interest and a prominent place in the affairs of the retail trade in New York State. Secretary Robert A. Wilson of the National Automobile Trade Association was present and explained the scope and objects of that body.

Tractors Worth $300,000 Shipped to Russia

Baldwin Locomotive Works Sends Special Train Across Continent to Seattle

York, Pa., March 3—One of the largest shipments of motor tractors to Russia, on the large contract being filled by the Morton Truck and Tractor Company of Harrisburg, was sent this week to Seattle, Wash., for export shipment. The total value of the shipment is $300,000. A solid train of sixty cars, each car loaded with a truck, was used for transporting the large war order.

The tractors were built at the plant of the Baldwin Locomotive Works, Philadelphia, on a sub-contract, and two weeks ago were shipped from the Quaker City to New York. Owing to the freight blockade at the New York terminal the cars were tied up in freight yards in the metropolis. Upon receipt of notice to rush the shipment as rapidly as possible and in view of the fact that railroad officials are unable to say how soon the blockade in the East will be lifted, the Harrisburg company believed that considerable time could be saved in shipping West, notwithstanding that the route to Russia *via* Seattle is 5000 miles further.

The Pennsylvania railroad handled the special train as preference freight with instructions to permit no delays at division terminals. Each truck is packed in a large box which takes up all the room on a gondola, 60 ft. long. Assurance was given by the railroad company officials that a boat would be ready at Seattle to take the shipment.

Chicago's Amateur Speedway Race May 20

Chicago, Ill., March 8—Entry blanks have been sent out by the Speedway Park Assn., this city, for the Western Interclub, non-professional automobile race at Speedway Park, on May 20. The race is for Class E, non-stock cars with a special invitation for fully equipped roadsters. The event is under the auspices of the Chicago Automobile Club and other leading clubs of the West.

The Western Interclub Cup has been offered and will become the permanent property of the driver winning the event three times. A gold brassard will be given the winner of each heat held on the speedway.

The contest will consist of four heats, three preliminary heats, and one final. The preliminary heats will be 20 miles or ten laps of the course, and the final will be 30 miles or fifteen laps of the course.

Maibohm Roadster Announced

New Car Is Product of Maibohm Motors, Racine—Four Cylinder Model $595

RACINE, WIS., March 6—The Maibohm roadster has been introduced and is to sell at $595. This car is of the light car type with low-hung and distinctive lines. This car is the product of the Maibohm Motors Co., Racine, Wis., recently formed and headed by H. C. Maibohm, formerly connected with the Locomobile Co. of America and until recently president of the Motor Supplies Co. Associated with him are P. C. Maibohm, former president of the Maibohm Wagon Co., and J. R. Foster, former president of the Foster-Lockwood Oil Co.

Temporary manufacturing facilities have been secured in Racine and negotiations are now pending for a permanent factory site. The company will produce 2000 cars during the first year, two-thirds of which are said to be already sold to dealers. Particular attention has been paid to the comfort of passengers, the seats being unusually low and on an almost direct horizontal line with the pedals which are adjustable to any desired leg room. The steering post is also adjustable to the requirements of the operator.

Four Cylinder 3 by 5

The four-cylinder, valve in head motor is provided with three-point suspension and is rated at 14.4 hp., having 3 by 5-in. cylinders. It has a detachable cylinder head.

Lubrication is by constant level splash under the connecting-rods and pump to the three main bearings. Cooling is thermo-syphon with extra large inlet and outlet manifolds cast integrally with cylinder block. Ignition is Atwater-Kent with automatic spark advance, current being supplied by a 6-volt 100-hr. battery located under the seat in a steel hanger. Starting and lighting is by an inclosed silent chain drive single-unit system which is attached to front gear case. Fuel is gravity supplied by a 10-gal. gasoline tank located in the dash cowl.

The frame is a pressed steel channel section 3 by ⅛-in., curved over the rear axle to permit underslung semi-elliptic rear spring construction. The wheelbase is 105-in. and size of tires is 30 by 3½. Wood or wire wheels are supplied at the option of the purchaser. Throughout the chassis, with exception of motor, Hyatt and Timken bearings are used.

The gearset is compact in form and with the dry-disk clutch is supported to the rear of the motor. Three speeds are used and center control levers are conveniently placed. The Hotchkiss system of propulsion is used and the master leaf of each rear spring has been strengthened by the use of a special heat-treated steel.

Both front and rear springs are of the semi-elliptic type, 2 in. wide and almost flat. The rear unit is built along standard lines with a pressed steel housing that carries the weight of the car and relieves the driveshaft from any duty except propulsion of the car. Equipment features include electric starting and lighting, a flush type speedometer and lock switch, electric horn, rear tire carrier, one-man top, tools, etc.

Lane Heads Truck Co.

KALAMAZOO, MICH., March 2—M. H. Lane has been elected president and general manager of the recently organized Lane Motor Truck Co. G. E. Bardeen, Jr., is secretary-treasurer. The first model is expected to be out about March 15. It will be of the worm-drive type.

Speeds Up Gasoline Price Investigation

WASHINGTON, D. C., March 6—At the request of several members of Congress the Federal Trade Commission is preparing to speed up the investigation of the increase in the cost of gasoline. Joseph E. Davies, chairman of the commission, has appointed Lewis E. Haney of Austin, Texas, chief counsel in charge of the investigation. Haney will be aided by a corps of experts, and everything possible will be done to hurry the inquiry.

Report Due Soon

All complaints to the Department of Justice regarding the rise in price of gasoline have been referred to the Federal Trade Commission. It was announced some time ago by Commissioner William J. Harris, who has been in active charge of the inquiry, that about three months would be required to complete a report. This has prompted the California Congressional delegation and other Congressmen to threaten a Congressional investigation if the commission did not give assurances that a report would be made within a few weeks.

Overland Reaches 100,000 Mark

TOLEDO, OHIO, March 2—The 100,000 mark was reached by the Willys-Overland company last Monday with shipments to date more than treble those reached a year ago. Overland dealers now number nearly 5000 in this country and Canada. Foreign dealers number about 500.

Industry Ranks Fifth in Exports

Well Up in List of Manufactured Articles—Gained 232% in 1915

NEW YORK CITY, March 6.—Automobiles and parts rank fifth in value among all manufactured articles exported from the United States, according to an analysis by the National Automobile Chamber of Commerce of the statistics contained in the December report of the Department of Commerce. The relative value of the leading manufactured articles exported during 1915 is:

Iron and steel	$338,703,720
Explosives	181,778,033
Refined mineral oils	138,689,495
Copper and manufactures	125,136,289
Automobiles and parts	111,180,139
Wheat flour	96,201,234
Cotton and manufactures	95,827,024
Other machinery	81,224,345
Chemicals, drugs, etc	80,395,321
Locomotives, vehicles, etc	78,015,574
Leather and manufactures	75,268,680

In one year the exports of motor vehicles increased more than 232 per cent—from a total value of $28,507,464 in 1914 to $94,879,738 in 1915. The foreign shipments of passenger cars almost doubled—from 22,335 valued at $19,521,708 in 1914 to 41,869 valued at $35,045,492 for the year ended December 31, last. But the exports of trucks increased nearly seven-fold, from 3,430 worth $8,985,756 to 22,082 valued at $59,834,246.

Truck Increase Large

Growth of the foreign trade in American motor trucks during the last two years is even more noteworthy, for in 1913 only 1,009 commercial vehicles were exported, of a gross value of $1,686,807, the increase in two years being 3447 per cent.

Hudson Adds 641,600 Sq. Ft. in Five Years

DETROIT, MICH., March 3—In five years, from 1910 to the end of 1915, the Hudson Motor Car Co. has added a total of 641,600 sq. ft. of floor space to its plant. In the original building there was a total of 172,282 sq. ft. of floor space. In 1912 new constructions added 72,422 sq. ft.; in 1913 there was an increase of 82,744 sq. ft. of floor space. The following year 53,370 sq. ft. were added and in 1914 the additions totaled 104,574 sq. ft. It was, however, last year when the biggest new area was added to the plant, the new buildings put up and the additions of floors to other buildings providing a total of 328,490 sq. ft. of new constructions, or more than half the total put up since 1910. The total area now occupied by the Hudson plant contains 813,882 sq. ft. of floor space.

Kerosene as Fuel for Automobiles

Colorado State Inspector Starts Campaign for Educating Automobile Users

DENVER, COL., March 4—A campaign to meet the condition of high-priced gasoline by substituting kerosene for use in combustion engines has been started by Colorado State Oil Inspector James Duce, assisted by Prof. John A. Hunter, professor of mechanical engineering in the University of Colorado. After extensive experiments, their first public step toward educating motor car owners and other users of gasoline engines was made yesterday in the way of a meeting at the State house for a general discussion of the fuel problem and the technical points involved in using kerosene. The meeting was attended by representatives of the Automobile Trades Association of Colorado and the Denver Motor Club, by tractor, and oil men and a goodly number of individual motor car and tractor users.

Kerosene Gives More Power

It was shown that tractor motors built originally for kerosene usage develop as much power from a gallon of kerosene costing 12 cents as can be produced by a gasoline tractor from a gallon of gasoline costing 23 cents, while slight mechanical changes will enable a regular gasoline motor for motor cars to develop equal power from about one-fourth more kerosene than gasoline, making the cost ratio for practically the same power in motor cars 16 cents for kerosene as against the present Denver price of 23 cents for gasoline. It was urged that the added difficulty of handling kerosene motors could easily be overcome by careful study of required methods of handling, aided by rapidly advancing engineering improvements, and that the question of more unpleasant odor from kerosene could be largely disposed of by practical education against established prejudice along this line.

Inspector Duce's records show that Colorado consumed about 15,000,000 gal. of gasoline during 1915, a gain of 45 per cent over the previous year. He argues that the most practical way to check the alarming advance in the price of gasoline is to substitute kerosene, which has become a by-product of the oil refineries, particularly those operated by independent concerns.

The present gasoline price of 23 cents, which is the highest on record for Denver in fifteen years or more, has been reached by a rapid series of one-cent jumps during the last ten months from 12 cents, which was the lowest price ever recorded here in twenty years.

Professor Hunter and other engineers at the State university at Boulder, where gasoline is now 28 cents, are experimenting along all lines of mechanical developments required to insure the success of using kerosene as a motor fuel, and declare themselves ready to furnish practical information and suggestions to all inquirers as an aid to Inspector Duce's Statewide campaign for kerosene tractoring and motoring.

Fisk Shows Good Profit Increase

CHICOPEE FALLS, MASS., March 4—The annual report of the Fisk Rubber Co. for the year ended Dec. 31, 1915, shows net profits of $1,791,579 as compared with $942,204 in 1914. The report states that, in accordance with the first preferred stock provision, there were retired Dec. 31, 1915, out of profits of the company 3750 shares of the first preferred stock, which, with the first preferred stock previously retired, represent the par value of $600,000.

The company reports the following income statement for the year ended Dec. 31, 1915:

	1915	1914
Net profits	$1,791,579	$942,204
Reserve for inventories	145,160	160,000
Balance for dividends	$1,646,579	$782,204
First preferred dividend	219,042	210,000
Second preferred dividend	140,000	140,000
Total dividends	$359,042	$350,000
Surplus	$1,287,537	$432,204
Previous surplus	619,267	187,063
Total surplus	$1,906,804	$619,267
Deductions	660,410	....
	$1,246,394	$619,267

The balance sheet as of Dec. 31, last, follows:

Assets	1915	1914
Capital assets	$12,428,564	$12,461,364
Inventories	4,531,377	2,622,721
Tires in use	40,066	49,899
Due on notes	128,955	175,482
Notes and accounts receivable	1,330,208	2,131,577
Cash	991,909	362,644
Deferred charges	127,273	84,609
Total assets	$19,578,352	$15,888,296
Liabilities		
Capital stock	$14,775,000	$13,000,000
Notes payable	2,200,000	1,745,000
Accounts payable	577,650	228,525
Dividend not paid	807	37
Reserve for contingencies	178,502	207,967
Surplus appropriation for retirement of preferred stock	600,000	....
Profit and loss surplus	1,246,394	619,267
Total liabilities	$19,578,352	$15,888,296

Maise with Springfield Metal Body

DETROIT, MICH., March 4—Herman Maise who was formerly with the Fisher Body Co., here, and with the W. F. Stewart Co., Flint, Mich., both body makers, has recently joined the Springfield Metal Body Co., Springfield, Mass., in the capacity of chief engineer.

Reo Expects General Price Rise

Cost of Materials and Tools Must Affect Selling Price Says R. C. Rueschaw

LANSING, MICH., March 4—The new and higher prices rather than the new models will be the feature of the 1917 announcements of the automobile manufacturers, according to sales manager R. C. Rueschaw of the Reo Motor Car Co.

Mr. Rueschaw has made an investigation of the general conditions prevailing among those concerns which supply raw material, other products and also machinery necessary to the automobile manufacturer. From the data gathered by George E. Smith, who is manager of the purchasing department of the Reo company, it seems, according to Mr. Rueschaw, that there is no other possibility for the motor car manufacturer than to increase his prices for next season. Not only are prices of materials at the present time without a parallel in the history of the automobile industry, but, there is no hope for a betterment of this condition.

Freight Car Is Big Trouble

Aside from the question of prices of materials, Mr. Rueschaw believes that the shortage of railroad freight cars is another reason for prices to be increased, because it will compel some factories to slow down and thus will cause an extension of the date on which the present factory run, that is the 1916 output, is to be completed. This means that instead of completing the schedule by July 1, it will probably be some time during autumn before it is completed. This unanticipated and unremediable course will thus very likely affect the price of the cars of those manufacturers.

"The present market situation was foreseen by us," said Mr. Rueschaw, and we started early to fill our warehouses so that at the present time we have not only practically everything we need up to the close of our fiscal year, but, we are also comfortably covered for most anything we will need for a year beyond that. Such action on our part was and is necessary considering the time required, or rather requested, for delivering goods ordered. For instance, orders for bar steels placed in December, 1915, will not be delivered until January, 1917. Ordinarily cold rolled bars cannot be secured in less than six months. We are able to buy odd lots of bar steel and forging steel in small quantities but at twice or three times the normal price.

"High speed steels have increased in price from 45 cents per pound to $3.

Sizes of Truck Motors and Outline of British Practice

(*Continued from page* 446)

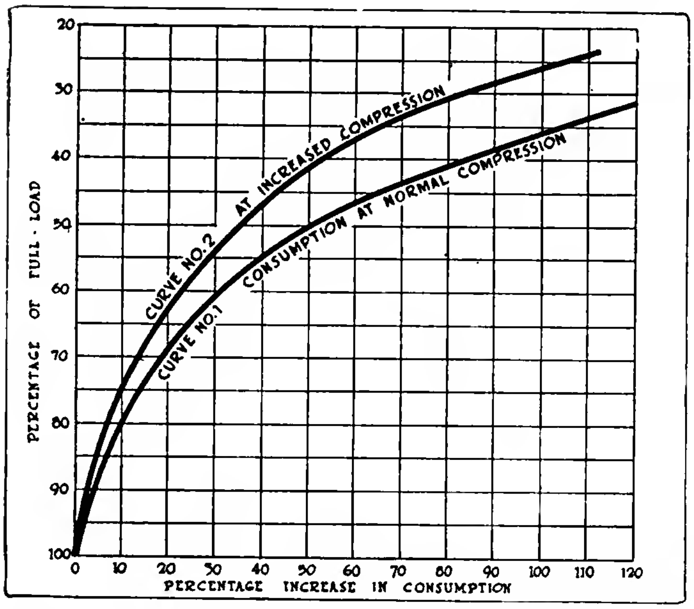

Fig. 4—Chart showing effect—with governed engine—of light loads upon consumption

and the equation becomes:

$$87 \times \frac{1000}{6} \times V = W \times \frac{3995 \times 11.5 \times 1760 \times 3}{30 \times 60}$$

or $V = W \times \dfrac{3995 \times 11.5 \times 1760 \times 3 \times 6}{30 \times 60 \times 1000 \times 87}$

$V = 9.3\ W$ approximately.

$Q = 9.3$.

The curve showing the relation of torque to road resistance is Curve 2 in Fig. 2, and the gradients the vehicle is capable of climbing on top gear at various speeds are shown in Curve 2, Fig. 3.

Gasoline Consumption

Having found the engine size for the gradient desired, the cost of this climbing power in gasoline consumption should be examined. Taking the original engine with "Q" = 5.5, and assuming the vehicle is on the level with a total resistance of 71.5 lb. per ton and a consumption of 0.58 pints per b.h.p. per hour, then for 0.58 pints

the work done =

$$33{,}000 \times 60 = 1{,}980{,}000 \text{ ft.-lb.},$$

and for 1 gal. the work done =

$$1{,}980{,}000 \times 13.8 = 27{,}324{,}000 \text{ ft.-lb.}$$

One ton of gross weight absorbs, per mile, on the level:

$$71.5 \times 1760 \times 3 = 377{,}000 \text{ ft.-lb.}$$

The consumption would therefore be

$$\frac{27{,}324{,}000}{377{,}000} = 72.5 \text{ ton-miles per gallon.}$$

In the case of the engine with "Q" = 9.3 it is capable of giving out at full load a torque to overcome a road resistance at 15 m.p.h. of 121 lb. per ton, but is only using 71.5 lb. per ton or about 59 per cent.

Reference to Curve 1, Fig. 4, shows that this means an increase in consumption of 33 per cent. The consumption per b.hp. per hour rises to 0.77 pints, and the ton-miles per gallon falls to 54.5. Probably 75 or 80 per cent of the distance traveled is on level, or almost level, roads, and this increase in consumption serves to show the cost of the reserve power considered necessary for hill climbing. As far as current practice is concerned, this would be looked upon as quite a reasonable result.

Curve 2 on Fig. 4 shows the improvement that can be obtained at decreased loads by increased compression. This curve was taken from the same engine as Curve 1. The increased compression made the engine very prone to knock at low speeds with full throttle opening. This knocking commenced at about 700 r.p.m., or, in other words, at about the speed at which a change of gear should be made to keep the engine within its range of minimum consumption.

Average Loads Versus Full Loads

It would appear than engine builders do not give sufficient attention to the fact that the normal condition of working is at about 60 per cent of full load.

Consumption curves are usually taken under full load, and the carbureter adjusted to give the best result under these conditions. Probably better consumption on the road would be obtained if the carbureter were set to meet these conditions of light load at which the engine is running for the greater portion of its time. Even though this lead to slightly decreased maximum torque and a slightly increased consumption at full load, the net result would be a decided gain.

Engine Sizes for Various Vehicles

Taking "Q" = 9.3 for 1300 r.p.m. and 15 m.p.h., Table A gives the engine sizes for various vehicles.

Table A (Q = 9.3)

Gross Weight of Vehicle		Cylinder capacity, cubic inches	Bore and stroke of engines, in inches, with approximately 1.3 ratio
4½	tons	41.85	3½ × 4½
5	"	46.5	3⅝ × 4¾
6	"	55.8	3 13/16 × 5
7	"	65.1	4 × 5¼
8	"	74.4	4 3/16 × 5½
*9	"	56.25	3 13/16 × 5
*10	"	62.5	3 15/16 × 5¼

---

*Twelve miles per hour.

Note.—For 9 and 10 tons gross weight the table is corrected for road speed and resistance, and "Q" therefore becomes 6.25 for these cases.

Current Practice in Engine Sizes

An examination of the engines in a number of successful types of commercial vehicles shows that the average ratio of engine speed to road speed is 1000 r.p.m. for 15 m.p.h., and that "Q" has a value of 12.5.

This agrees quite well with the 9.4 obtained for 1300 r.p.m. if the necessary correction be made for engine speed, as we have

$$\frac{12.5 \times 1000}{1300} = 9.64.$$

Stroke Bore Ratio

There does not appear to be any tendency to fix a definite ratio of stroke to bore. Examination of a large number of

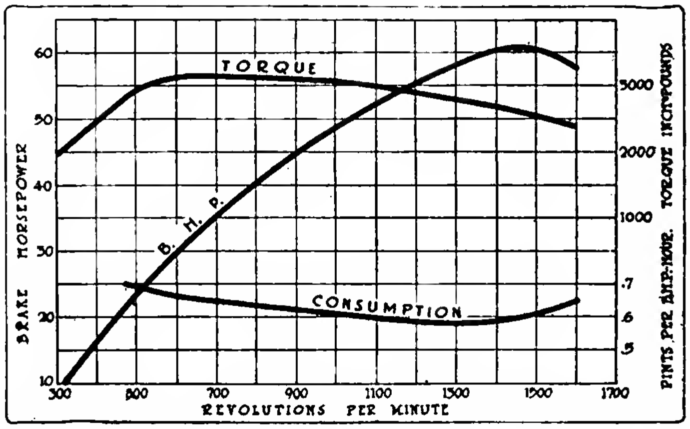

Fig. 5—Curves showing torque and consumption curves as taken from Tyler motor

motors showed an average of 1.3, but this figure would appear to be of little value since no maker appears to have two motors of different sizes with the same ratio. Curiously enough more than 50 per cent of the engines examined had strokes of 5½ in., and the tendency appears to be to have a range of engines to suit the various sizes of vehicles all having the same stroke. No doubt this arrangement materially decreases the number of jigs and allows for interchangeability of a number of parts, so cutting down cost of production.

Taking "Q" at 12.5, and allowing 15 miles an hour at 1000 r.p.m. for vehicles up to and including four-tonners, and 12 m.p.h., with the necessary correction, for five and six-tonners, Tables B and C give the engine sizes.

Table B (Q = 12.5)

Gross weight of vehicle	Cylinder capacity, cubic in.	Engine size suggested, inches	Engine size with 1-3 ratio, inches	Engine size with constant stroke (5½ in.)
4½ tons	56.25	4 × 4½	3¹³⁄₁₆ × 5	3⅝ × 5½
5 "	62.5	4¼ × 4½	3¹⁵⁄₁₆ × 5⅛	3¹³⁄₁₆ × 5½
6 "	75.	4¼ × 5½	4³⁄₁₆ × 5½	4³⁄₁₆ × 5½
7 "	87.5	4½ × 5½	4⁷⁄₁₆ × 5¾	4½ × 5½
8 "	100.	4¾ × 5¾	4⅝ × 6	4¹³⁄₁₆ × 5½
*9 "	75.	4¼ × 5½	4³⁄₁₆ × 5½	4³⁄₁₆ × 5½
*10 "	83.3	4½ × 5½	4⅜ × 5⅝	4⁷⁄₁₆ × 5½

---

*Twelve miles per hour.

The following table relates to the approximate weights of actual vehicles, and is based on the same lines as Table B.

Table C (Q = 12.5)

Useful load	Gross weight	Cylinder capacity, cubic in.	Engine size 1.3 ratio	Engine size with 5½ in stroke
2 tons	5 tons	62.5	3¹⁵⁄₁₆ × 5⅛	3¹³⁄₁₆ × 5½
2½ "	5.672 "	71.	4⅛ × 5⅜	4¹⁄₁₆ × 5½
3 "	6.56 "	81.25	4⁵⁄₁₆ × 5⅝	4⅜ × 5½
3½ "	7.56 "	93.75	4½ × 5⅞	4¾ × 5½
4 "	8.28 "	103.125	4¹¹⁄₁₆ × 6	4⅞ × 5½
5 "	10. "	83.3	4⅜ × 5⅝	4⁷⁄₁₆ × 5½
6 "	11.25 "	93.75	4½ × 5⅞	4¾ × 5½

By grouping, three sizes of motors can be used for the seven vehicles in Table C, any small discrepancy being easily regulated by adjustments in gear ratio; the arrangement might be as follows:

Table D

Engine size:	4 in. × 5½ in.	4⅜ in. × 5½ in.	4¾ in. × 5½ in.
Useful load of vehicle:	2 and 2½-ton vehicles	3-ton and 5-ton* vehicles	Subsidy type 4 and 6-ton

---

*Twelve miles per hour.

Heavy Passenger Vehicles

For motor char-a-bancs, which are expected to have greater climbing ability on top gear, the gradient may be taken as 1 in 24, to be climbed at 12 m.p.h., with the engine running at 800 r.p.m.

$$\text{Then } 87 \times \text{Volume} \frac{800}{6} = W\left(60 + \frac{2240}{24}\right) \times 12 \times 88,$$

$$\text{or} \quad 87 \times \text{Volume} \times \frac{800}{6} = \frac{1440\ W + 2240\ W}{24} \times 12 \times 88,$$

$$= \frac{3680}{24} W \times 12 \times 88,$$

$$\text{and Volume} = W \frac{3680}{24} \times \frac{12 \times 88 \times 6}{800 \times 87} = W \frac{6072}{435}$$

Or Volume = 14 W approximately.

Taking as an example a 30-seated vehicle weighing, when loaded, 6 tons, we get:

Gross weight.	Cylinder volume	Cylinder size.
6 tons..........	84 cu. in.....	4⁷⁄₁₆ in. × 5½ in.

In the last named case one of the three standard sizes suggested might be used, namely, 4⅜ in. by 5½ in. with suitable gear correction.

The curve in Fig. 6 shows current American practice, and is based on the average of 160 vehicles.

Part 2—Outline of British Truck Motor Design

Design features in British commercial vehicles which are more or less affected by the nature of the vehicle service, are referred to in the following:

Compression Pressure

An examination of a number of engines shows the average ratio of total volume to swept volume to be 4.4, and if the compression is calculated on $PV^{1.3}$ = Constant, with 13 lb. initial pressure, this shows a gage pressure on compression of about 75 lb., and an explosive pressure which, under ordinary conditions of cylinder shape and cooling, might be taken at 280 lb. per square inch.

Connecting-Rod Bearings

Coming to the bearing surface usually allowed for the big end of the connecting-rod, the practice of manufacturers shows an average of 765 lb. per square inch on the projected area. The highest pressure observed is about 950 and the lowest about 620 lb. per square inch. Neglecting the pressure and taking into account only the respective areas of cylinder and bearing, an average of 1 sq. in. of big end area for 2.73 sq. in. of piston area is obtained. In the limits of the engines under consideration, say from 3½ in. bore to 5 in. bore, the average diameter of the crankpin in use corresponds very closely with 0.4 bore + ¼ in.

Gudgeon pin pressure may be taken at 2100 lb. per square inch,

or the area of the pin is given by $\frac{D^2}{9.6}$ in square inches, D being the diameter of the cylinder.

Gudgeon pin diameters show a close approximation to big end diameter — 1 1/32 in. for the sizes of engines under consideration.

In commercial vehicle engine design, the three-bearing crankshaft is usually used, and there would appear to be no particular reason for fitting five bearings. At the same time there are two or three very successful engines having five-bearing crankshafts, and one at least with only two main bearings.

(To Be Continued)

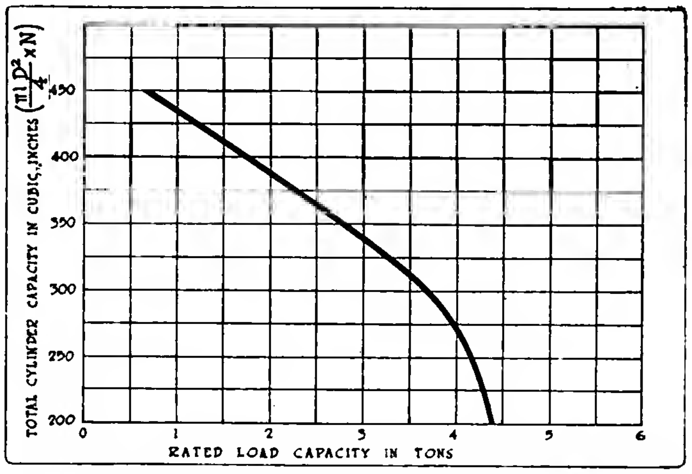

Fig. 6—Chart showing relation between total Cylinder capacity and useful load in American commercial vehicles

South's Profits $10,000,000,000—Sales Gain

(*Continued from page* 462)

of July that year. The avenues of trade shrank until they became mere alleys and in some cases ceased to exist. Then followed another twelvemonth in which business grew somewhat, and while the latter half of 1915 was far better for lumbermen than they had anticipated, the gain was not sufficient to put production back on the basis from which it was routed at the beginning of hostilities abroad. In support of this statement, note the table given herewith, showing the production of lumber in board feet in 1914 and 1915 from the several States south of the Ohio River and east of the Mississippi:

Production of Lumber—Board Feet

State	1915	1914
Arkansas	992,292,000	1,022,874,000
Texas	1,226,129,000	1,231,166,000
Louisiana	2,999,430,000	3,102,055,000
Mississippi ...	1,196,444,000	1,279,181,000
Alabama	596,550,000	662,638,000
Georgia	235,554,000	275,190,000
Florida	646,892,000	620,769,000
South Carolina	370,180,000	311,960,000
North Carolina	625,492,000	628,340,000
Virginia	259,772,000	231,800,000
West Virginia.	530,119,000	572,320,000
Kentucky	100,479,000	112,819,000
Tennessee	159,868,000	211,496,000
Total	9,939,201,000	10,262,608,000

Business done so far in 1916 is far ahead of that of the preceding year, and it appears that the predictions of the lumbermen of the South are to be realized. The South has bought many cars in the last year, and with a healthy tone of optimism to the so-called barometer of trade, it augers very well for the sale of cars during 1916.

$100,000,000 for Lumber

Granting that $10 per 1000 ft. is an average price of lumber at the mills, the foregoing figures show that approximately $100,000,000 came into these States during both of these years. Perhaps $10 a thousand is too low a figure; we know it is if we are to take the price we have to pay for it out of the city and country yards where lumber is not produced. It costs us about twice or three times that amount.

Lumber and lumber products should bring into the coffers of the South from $100,000,000 to $200,000,000 during 1916. The percentage of this that is turned over to automobile dealers will be governed very much by their aggressiveness. The lumber branch of revenue production is but one factor that contributes to the prosperity of the South, so it seems a safe wager that this year will see more cars sold south of the Ohio than in any preceding year, especially with the good roads agitation and the touring sections being exploited now as never before.

Railroads are buying timber for making cars, and much of this material comes from the South. Long-leaf yellow pine is specified in a great many cases and the railroads are preparing for a new era of prosperity in general. When the railroads begin to add to their equipment, especially the complement of freight cars, it means that they are practically sure that there will be need for them. Every railroad leading into Chicago has contracted with car makers or for material for the construction of additions to its rolling stock, especially freight cars. This will redound to the benefit of the South in two ways—it will create a good demand for material, good demand stimulating prices, and it will bring additional money to the South with which to purchase the necessities and the luxuries.

Iron and Steel Industry in South

THE South makes important contributions to the great iron and steel industry, especially Alabama, Georgia, Kentucky and Tennessee, Louisiana and Texas also deserving some mention in this particular. There are seventy-six blast furnaces in the six States, of which forty-nine were in operation a year ago, their combined output of pig iron being 2,280,070 tons, as compared with a capacity of 4,885,400 tons for the year. There are fifteen steel works, of which twelve were active a year ago, their total output for the year showing 737,037 tons of steel ingots and castings, the total annual capacity being 1,443,225 tons. Of twenty rolling mills, seventeen were working a year ago, their production for the previous year totaling 626,305 tons of rolled iron and steel products for the six States. The 5,328,911 tons of iron ore produced in this district during the same year, combined with the 44,809,714 tons of coal and 3,816,752 tons of coke, serve to give an idea of the magnitude of these industries in this region.

Alabama Leads in Steel

As shown in the accompanying tabulation, Alabama is the leader, having forty-eight blast furnaces, of which thirty were in operation a year ago, producing 1,826,929 tons of a capacity of 3,660,000 tons of pig iron during the year. Out of

Statistics of the Iron and Steel Industry in Six Southern States at the end of 1914*

State	Number Blast Furnaces	Number Active Furnaces	(Pig Iron) Capacity of Furnaces, Tons	Tons Pig Iron 1914 Output	Number Steel Works	Number Active Works	Capacity of Works, Tons	Steel Ingots and Castings, Output, Tons	Rolling Mills	Active Mills	1914 Tons Output Rolled Products	Production Iron Ore, Tons	1914 Prod. *From the Annual Statistical Report of the American Irou and Steel Institute.

five steel works in the State, three were active last year, producing, in conjunction with the one in Georgia, 572,073 tons of steel ingots and castings, out of a capacity of 1,055,000 tons. With seven out of nine rolling mills active, Alabama produced 413,654 tons of rolled iron and steel. It is significant that of the total of 5,328,911 tons of iron ore produced during the year, this State was responsible for 4,838,959, while its coal production was 15,993,422 tons and its output of coke, 3,084,149.

Kentucky and Tennessee are well represented in the production statistics of the iron and steel industry. Kentucky has six blast furnaces, five being in operation a year ago, producing 236,393 tons of pig, as compared with a total annual capacity of 314,250 tons. Two steel works in each of the two States show an output of 164,009 tons of steel ingots and castings, their total capacity being 380,000 tons. Six of the seven rolling mills in Kentucky were active a year ago, their output, combined with that of North Carolina's mills, totaling 151,422 tons. The coal industry of Kentucky is larger than in any of the other five States mentioned, producing 20,382,763 tons annually, the output of all six being 44,809,714. The iron ore production of Kentucky, combined with that of West Virginia, Maryland and North Carolina, was 91,966 tons during 1914, while the coke output for Kentucky alone was 443,959 tons.

Tennessee had fourteen of eighteen blast furnaces working at the beginning of 1915, the production for the previous twelve months being 216,738 tons of pig, compared with an annual capacity of 781,650 tons. Tennessee's production of iron ore for the year was 330,214 tons, while 264,127 tons of coke and the 5,943,258 tons of coal give an inkling of the magnitude of other branches of the iron and steel trade in this State.

Georgia a Steel Producer

Georgia has four blast furnaces with an annual capacity of 129,500 tons of pig iron, although none were in operation at the end of 1914. Its steel works, however, produced a good share of the total of 572,073 tons of steel ingots and castings given for Alabama and Georgia. Its capacity is 60,000 tons a year. Georgia's two rolling mills, combined with one each in Tennessee and Texas, produce 61,229 tons of rolled iron and steel for the year. Iron ore to the extent of 67,772 tons, with 24,517 tons of coke and the 166,498 tons of coal mined in Georgia and North Carolina were other products for 1914.

Louisiana and Texas do not contribute quite as largely as the other States mentioned to the iron and steel industry of the country, but their steel works, rolling mills and the 2,323,773 tons of coal produced by Texas are worthy of attention. These States have two steel works each, their combined capacity being 2225 tons of steel ingots and castings, of which 955 tons were produced in 1914. Texas also has one rolling mill, its output being included in the 61,229 tons of rolled products credited to the three States, Georgia, Tennessee and Texas.

Car Registrations Gain Steadily

THOUGH the increase in car registration in the States of Alabama, Florida, Georgia, Kentucky, Louisiana, Mississippi and Tennessee has not been phenomenal, it has been steady and fairly consistent. It is only recently that several of the group have kept records of their automobile and motor truck registration, so that some of the statistics for previous years are necessarily estimates.

At the end of 1915 there were 120,126 cars and trucks in use in the States mentioned, this being a gain of 40,727, or 51 per cent over the 1914 total of 79,399. It must be pointed out that this apparent increase is somewhat misleading as the 1914 statistics for Louisiana and Mississippi were estimates made in the absence of official records and proved to be very low as compared with the 1915 figures. Probably the actual gain is nearer the average increase for the entire country, which is 39.6 per cent, including all the States.

1915 INCREASE IN REGISTRATIONS IN SEVEN STATES

State	Registration in 1914	Registration in 1915	Car Increase	Per Cent Increase
Alabama	8,425	13,798	5,373	64
Florida	11,366	13,123	1,757	15
Georgia	20,800	24,059	3,259	16
Kentucky	11,746	19,500	7,754	66
Louisiana*	3,500	10,880	7,380	210
Mississippi*	3,894	11,500	7,606	195
Tennessee	19,668	27,266	7,598	39
Total	79,399	120,123	40,727	....
Average per cent increase	....	....	....	51
Average for U.S.	....	....	....	39.6

*1914 registration statistics in Louisiana and Mississippi were estimates made in the absence of official records and proved to be low as compared with the 1915 figures so that the apparent gain is in excess of the actual increase.

POPULATION AND CAR REGISTRATION

State	Pop. to Jan. 1, 1916	Cars Reg.	Pop. per Car
Alabama	2,316,943	13,798	168
Florida	882,148	13,123	67
Georgia	2,836,177	24,059	117
Kentucky	2,372,412	19,500	121
Louisiana	1,815,218	10,880	167
Mississippi	1,939,226	11,500	168
Tennessee	2,279,691	27,266	84
Total	14,441,815	120,126	....
Average population per car	......	....	120

Average population per car for the entire United States is 42.

Many People Per Car

Something that cannot be misinterpreted, however, is the striking difference between the population-to-car ratio of the entire country, 42 to 1, and that of the seven States mentioned, 120 to 1. Of course, this is largely due to the preponderance of the impecunious negro element in the population of these States, but even allowing for this, there would seem to be a considerable margin of persons able to buy cars.

Tennessee and Georgia are the leaders of the group in total registration, Tennessee having 27,266 cars and trucks, or one to every eighty-four of its population, and Georgia 24,059, one to each 117 of its inhabitants. Tennessee's increase over 1914, however, was 7598 cars and trucks, or 39 per cent, as compared with only 3259, or 16 per cent, for Georgia. During the five years since 1911, Tennessee added 20,802 cars to its lists with only 11,819 credited to Georgia.

Kentucky's Gain Largest

Kentucky ranks third of the seven States, having 19,500 automobiles and trucks in use at the end of 1915, a gain of 7754, or the largest of the group. The 66-per cent gain seems small as compared with the 195- and 215-per cent gains apparently made by Louisiana and Mississippi, but it must be remembered that these are probably far in excess of the actual increase in registration in these States, as the only statistics available up to 1915 were estimates, which

CAR AND TRUCK REGISTRATIONS BY YEARS SINCE 1911

State	1911	1912	1913	1914	1915	Increase in 5-Year Period
Alabama	2,856	3,385	5,435	8,425	13,798	10,942
Florida	3,889	6,749	8,372	11,366	13,123	9,234
Georgia*	12,240	19,120	18,500	20,800	24,059	11,819
Kentucky	2,868	5,147	7,210	11,746	19,500	16,632
Louisiana*	4,867	7,000	7,200	3,500	10,880	6,013
Mississippi	1,240	2,895	3,000	3,894	11,500	10,260
Tennessee	6,464	9,973	14,103	19,668	27,266	20,802
Total	34,424	54,269	63,820	79,399	120,126	85,702

*Louisiana's report for 1914 was not complete owing to a new law going into effect about the time the census was made. The same applies to Georgia's statistics for 1912.

were purposely made conservative. Kentucky's population-to-car ratio, however, is not so creditable, being 121 to 1. Since 1911, Kentucky has added 16,632 cars and trucks.

Alabama, which ranks fourth, shows nearly as high a percentage increase in registration as Kentucky, having gained 5373 motor vehicles, or 64 per cent during 1915, giving a total of 13,798, with an increase of 10,942 since 1911. In respect to population-to-car ratio, Alabama ranks with Louisiana and Mississippi, being third from the bottom of the list of the entire United States, having 168 people per car, so it would seem that there is still ample opportunity for a considerable increase in the number of cars sold in the State.

Florida's Population Ratio Best

Florida is fifth of the group, its registration being only 675 below that of Alabama, though its gain over 1914 was only 15 per cent, or 1757 cars and trucks. Its gain since 1911 totals 9234 motor vehicles.

With respect to the population, Florida's registration makes the best showing of the group, there being only sixty-seven persons to each car or truck in use in the State.

Mississippi and Louisiana stand sixth and seventh, respectively, Mississippi registering 11,500 motor vehicles up to the end of 1915, and Louisiana having 10,880 on its lists. The number of people per car in these two States is unusual, as compared with other States in the country, Mississippi having 168 and Louisiana 167, so that they rank respectively second and fourth from the bottom of the list of the United States.

Security Prices Lower

General Motors Drops 16 Points — Maxwell and Studebaker Lower

New York City, March 7—A further decline in automobile security prices occurred last week. With the exception of a few issues, the majority showed declines. Those issues which equaled or passed under their low marks for 1916, have established new low marks for this year. General Motors is still quoting considerably ahead of its rock bottom price of 415, though it declined 16 points last week, reaching 460. Maxwell common, first preferred and second preferred all dropped. Its common has reached 59, a drop of 9 points in two weeks. The second preferred, which showed a little strength recently has joined the general decline with a 4-point drop.

Chevrolet, Packard and Willys-Overland were the features of the automobile issues with rises of 3½, 5 and 7 points respectively. Chevrolet has shown considerable strength on the report of $6,000,000 earnings for 1916. It is stated that the company will turn out 20 per cent more cars than were projected for 1917 at the time of public financing last fall.

Goodrich common went up 1¼ points, reaching 70¼. This company is stated to have a large quantity of crude rubber on hand which cost it under 60 cents per lb. The sales of this company in January increased 150 per cent over January a year ago.

Though the declines last week were frequent, they were, however, in the majority of cases small. Ajax Rubber dropped 2½ points to 68½; International Motors common and preferred declined 1 and 2 points; Kelly-Springfield new common went down to 67; New Departure common went down 2 points; Reo Truck and Car went down 1½ and ½ points; and Stewart-Warner common reached 84 at a decline of 2 points.

Further Rise in Market Prices

New York City, March 8—Market prices last week took another jump. With an exceptional demand for spot delivery the market as a whole is very strong. Of the metals, copper is the only one which at the present time lacks demand. The resumption of trading at London has failed to stimulate the demand for that metal and prices have declined as a result. Both electrolytic and lake copper dropped 1 cent a pound to 27½. Aluminum, Bessemer and open-hearth steel, lead, and tin, are now quoting at higher prices than last week. Aluminum has reached the record mark of 61 cents a pound, while Bessemer and open-hearth steel prices were raised to new high marks of $37 and $38 respectively per ton. Lead is scarce and the market strong at $6.70 per 100 lb. A number of the companies are selling lead only in limited quantities to their customers.

Though there was no material change in the crude rubber situation last week, the market, however, was somewhat more active and a firmer tone developed.

*Par value $10. †And accrued dividend.

Shipments are coming in regularly and the manufacturers are showing a better demand. Last week Para dropped 1 cent per pound to 77 cents, while Ceylon, first latex crepe remained constant at 94.

Gasoline has taken the long expected rise to 24 cents a gallon wholesale. A further rise is predicted. On top of the general rise in gasoline throughout the country comes the announcement of another rise in Pennsylvania crude oil to $2.50 per barrel. This new advance has been expected and it is thought that it will bring out the hoarded supply of crude held for the account of producers, in tanks and pipe lines. It is stated, however, that there is no hope that this increased supply will have any material effect on the present scale of gasoline prices.

N. Y. Gasoline Now 24 Cents a Gal. Wholesale

NEW YORK CITY, March 3—Automobile owners are now paying from 26 to 31 cents a gallon for their gasoline in this city. This fuel yesterday went up another cent in the wholesale market, reaching 24 cents. Consumers last year at this time of the year were paying from 14 to 17 cents a gallon.

Despite investigations on the part of Congress and the protests of the local trade associations, prices have continued to increase at the rate of about 1 cent a month.

Action will be taken by the leading trade associations in this State. It is stated that the New York Garage Assn., and the New York State Automobile Trade Assn., are preparing a combined attack on the stand taken by the oil producers.

The increase in the prices, it is explained, is on account of the increased demand for gasoline at practically any price by the warring nations for their trucks, cars and aircraft, the Mexican troubles, which stop the supply from that country, and the slide in the Panama Canal, adding to the cost of transportation from the California wells.

England Threatened by $1 Gasoline

Agitation to Prevent Private Use of Automobiles Grows—Opposition is Very Strong

LONDON, ENGLAND, Feb. 18—The extinction of all private motoring in England is threatened by a recommendation of the National Organizing Committee for War Savings that pleasure motoring should not be indulged in. The Committee states that this is a selfish and thoughtless form of extravagance affecting (1) Ships and men now employed in carrying oil and rubber for automobiles and bicycles; (2) Men at docks and railroads, carmen, etc., employed in handling these cargoes and in work connected with the importation of automobiles and bicycles; (3) Chauffeurs now engaged in driving and looking after automobiles; (4) Men now engaged at garages and shops all over the country repairing automobiles and bicycles; (5) Men engaged in the manufacture and handling of tires used on automobiles.

At present the move is nothing more than a recommendation, but an endeavor is being made to put a stop to all pleasure motoring by reason of a special tax on gasoline. It is hinted that gasoline, which now costs 50 cents a gallon will be raised to $1. Many of the daily newspapers are clamoring for this measure in order to put a stop to what they claim is a useless extravagance. Much use is being made of the claim that pleasure motoring has been forbidden in France and should also be tabood in England. This is quite incorrect, for although nobody can use an automobile in France without a special police pass renewable monthly, this pass is given to everybody of recognized honorability irrespective of what kind of service the car may be intended to perform. The measure is only a precaution against the use of automobiles by spies, criminals or suspected persons.

English motorists are making a vigorous protest against the suggestion that cars are being used to any important extent for pleasure riding only. The high cost of gasoline, the impossibility of obtaining chauffeurs, the general money tightness, have all caused an important diminution in the number of cars in general service. It is difficult to say what is legitimate and what illegitimate motoring, or to devise a scheme which will allow gasoline to be used for the one and to prevent its use for the other. Practically all automobiles in service at the present time are utility vehicles and are used as such for 90 per cent of their mileage. If a remedy is sought by putting an additional tax on gasoline, it will hit hardest at men to whom a car is an absolute necessity. The suggested system of licenses is almost impossible of application, for it would be exceedingly difficult for any body of judges to say in which cases the use of an automobile was justified and in which it was not, or how much useful work must be done by the owner to justify him using the automobile on one occasion for either health or pleasure. In general motorists are of the opinion that the present high cost of gasoline has been quite sufficient to put a stop to all pleasure use of the automobile.

Texas Trouble Now Settled

NEW YORK CITY, March 4—The several automobile manufacturing companies recently sued in Texas for a violation of the anti-trust law of that State, on the ground that they limited the territory of the dealer, as is common practice throughout the country, have agreed to accept consent injunctions. These injunctions prohibit them from limiting their dealers to definite territory so that the manufacturers are changing their contracts with the dealers to comply with the law. In doing this, however, the manufacturers feel that the dealers, as well as the general public, will not profit by the change since a man may buy a car of a dealer several hundred miles from his home but he cannot expect that the local agent of the same car will give him service on a car bought from another dealer. This is only one example of the disadvantages of the new arrangement, the general tendency being to relieve the dealer of all responsibility as to service, etc.

U. S. Rubber Sales $92,861,015

NEW YORK CITY, March 8—Net Sales of the U. S. Rubber Co., for the year ended Dec. 31, 1915, amounted to $92,861,015, as against $83,678,812 in the preceding year. The net profits before deducting interest charges were $11,486,705, compared with $9,776,873 in 1914. The surplus was $2,882,048 against only $721,951 for the previous year.

Colonel Colt announces that the sales of the United States Tire Co., for January and February showed a very large increase over the corresponding period of last year. The organization of the United States Tire Co. has recently been enlarged and strenghtened. In addition to the distribution of tires through the fifty-one branches of that company, provision has been made for a very much wide distribution through the stores of the U. S. Rubber Co. Colonel Colt added that at no time in the company's history had there been greater activity in its business than now. All the factories, he stated, were working at capacity and steps were being taken to enlarge several of the plants, one of them being the Morgan & Wright factory in Detroit. This work is well under way and when completed will double the capacity of that plant.

Eighth Edition Used Car Report

CHICAGO, ILL., March 4—The eighth edition of the National Used Car Market Report of the Chicago Automobile Trade Association has been issued. In appearance and size it is exactly like its predecessors, the essential difference being in the figures given for the various cars listed. In the seventh edition the figures were given for sales made between June 21 and Sept. 21; the new edition gives figures for sales of used cars between Sept. 21 and Dec. 21. The number of cars listed shows but one change, the Mora failing to appear in the new book. The number of dealer associations and manufacturers supporting the movement also remains practically unchanged.

Thomas Neal Joins Signal Truck

DETROIT, MICH., March 6—Following closely upon the announcement of the increase of the capital stock of the Signal Motor Truck Co., from $85,000 to $550,000, comes the further information that Thomas Neal, former president and chairman of the executive committee of the General Motors Co., has been made a director and elected chairman of the executive committee of the Signal company, but will retain his connection with the Acme White Lead & Color Works.

At the same time Mr. Thomas Neal was elected a director, Myron W. Neal, treasurer of the Acme White Lead & Color Works, Detroit, and W. K. Hoagland of Allerton, Greene & King, bankers in Chicago, were elected to the board of directors. The other members are A. C. Burch, John Squires and Murray Wendell.

The Signal company is to have a new plant on North Jefferson Avenue, near the plant of the Chalmers Motor Co. It is to be big enough to insure an increase of 300 per cent in its production as compared with that of the past year.

Studebaker Raises Some Prices

Small Increases Made on Prices of Passenger Cars—Trucks Unchanged

DETROIT, MICH., March 4— The Studebaker Corp. increased the price of five of its models on March 1. In the four-cylinder class the three-passenger roadster, formerly $825, is now listed at $850; the seven-passenger touring car, which was formerly listed at $845, now sells at $875; the landau-roadster, which was selling at $1,145, now sells at $1,150.

Of the six six-cylinder models, the price of two has been increased. The three-passenger roadster sells now at $1,060 instead of $1,025, and the seven-passenger touring car formerly listed at $1,050 now sells at $1,085. The price of the landau-roadster, $1,350; of the four-passenger coupe, $1,600; of the sedan, $1,675, and of the seven-passenger limousine, $2,500 remains the same. There is also no alteration in the price of the commercial car line, which was published in THE AUTOMOBILE, Feb. 24.

National Gas Assn. to Discuss Tractors

CHICAGO, ILL., March 8—Plans are nearing completion for the annual convention of the National Gas Engine Assn., which will be held at the Sherman Hotel, Chicago, June 27, 28 and 29.

"Tractor and Tractor Engines" will be the subject of one session, during which there will be a number of papers, including "Tractor Engines" by W. J. McVicker of Minneapolis, as well as a paper on "Carburetion," "Traction" and "Tractor Equipment" by well-known authorities, and a general discussion of such matters.

The use of kerosene and "Design of Oil Engines" will be taken care of by Professor Norris of Wisconsin University.

Detroit S. A. E. Meet March 17

DETROIT, MICH., March 4—The next meeting of the Detroit Section of the Society of Automobile Engineers will be held March 17, in the convention hall of the Hotel Ponchartrain. The speaker of the evening will be J. G. Perrin, chief engineer of the Timken-Detroit Axle Co., whose subject will be: "Evolution of the Rear Axle."

$30,000 in Prizes for Chicago Derby June 10

CHICAGO, ILL., March 8—Cash prizes amounting to $30,000 have been offered for the International 300 mile race to be held at Speedway Park on June 10. The race is open to Class E non-stock cars of 300-cu. in. piston displacement or less, with a maximum weight of 2500 lb.

There will be ten prizes divided as follows: first, $12,000; second, $6,000; third, $3,000; fourth, $1,500; fifth, $1,300; sixth, $1,200; seventh, $1,100; eighth, $900; ninth, $800, and tenth, $700. The car leading at 100, 200 and 250 miles, will receive $500 for each distance.

Timken Puts Up Seventh Building

DETROIT, March 6—The Timken-Detroit Axle Co. is now building a large addition which will be the seventh new building put up within the last year. This new structure will be known as the heat-treating plant and will cost approximately $300,000. It will be a three-story building 40 by 330 ft.

The heat-treating department will occupy the entire first floor while the upper floors will be used for manufacturing operations on the stock as it comes from the furnaces. There will be two specially-built rotary furnaces embodying in their design all the new scientific principles required for the heat-treatment of the many grades of steel used by the Timken company. There will be two large electric traveling cranes to handle the stock in the plant carrying it from furnace to furnace and from cooling vat to cooling vat.

The plant will be connected with the large new forge shop recently completed, by a tunnel which runs under the main building of the Timken plant. Through this tunnel, forgings will be brought to the heat-treating furnaces by electrical industrial trucks.

To Develop New Universal

NEW YORK CITY, March 8—J. E. Gramlich, formerly engineer and superintendent of The Chase Motor Truck Co. of Syracuse, N. Y., has severed his connection with that company to become associated with the Thermoid Rubber Co. of Trenton, N. J. Mr. Gramlich will act as engineer for the latter company, giving his time exclusively to the development of the lately patented Thermoid-Hardy laminated disk, for which this company has the exclusive American rights.

Fergus Motors Formed

ALBANY, N. Y., March 3—The Fergus Motors of America, Inc., was incorporated to-day to manufacture the Fergus car, shown in this country for the first time at the recent New York City automobile show. The capital stock of the company is $2,000,000 and the main offices are in East Chester, Westchester county. The directors of the company are C. T. B. Roew of Bronxville, Charles Blandy, Jr., New York City and F. F. Quantrell, Brooklyn.

Factory Miscellany

Canadian Crow to Add—The directors of the Canadian Crow-Elkhart Motor Co., Mount Brydges, Ont., is considering the enlargement of the plant.

Elgin to Build—The Elgin Motor Car Corp., Chicago, Ill., is having plans prepared for the erection of a $50,000 plant, 168 by 272 ft., at Argo, Ill.

Toronto Tire Co. to Enlarge—The Gutta Percha and Rubber Co.'s factory, Toronto, Ont., where Maltese Cross tires are manufactured, on West Lodge Avenue, will be enlarged.

Lane Truck to Build—The Lane Motor Truck Co., Kalamazoo, Mich., has taken temporary quarters in the Frank Burtt Building. A plant will be erected within the next two months.

Bour-Davis Buys Land—The Bour-Davis Motor Car Co., Detroit, Mich., has purchased a tract at Kercheval Avenue and the outer belt railroad, upon which to erect a factory.

Chevrolet Plant in Seattle—The Chevrolet Motor Co. has determined to establish an assembling plant in Seattle just as soon as the plant at San Francisco is completed. The Seattle factory will supply the entire Pacific Northwest.

Rock Island Top Co. Opens Plant—The Motor Row Top Co., Rock Island, Ill., making automobile tops, radiator covers, automobile upholstering and other special work, has opened a plant at 1818 Fourth Avenue. S. P. Pearson is general manager.

Bulkley-Rider to Build—The Bulkley-Rider Tractor Co., Los Angeles, Cal., has announced that as soon as a site can be decided upon, the company will begin the erection of a large factory with a capacity of twenty-five tractors per month. Plans for the factory have already been accepted and several sites are under consideration.

To Make Resilient Wheel—The Willson Resilient Auto Rim Co. will soon be organized at Columbus, Ohio, for the purpose of manufacturing a patented resilient rim, the invention of F. R. Willson, an electrical engineer at the Jeffrey Manufacturing Co. At a recent meeting of the stockholders F. R. Willson was elected president and H. H. Spain, secretary-treasurer.

To Make Tires in Baltimore—The Baltimore Rubber Tire Mfg. Co., Baltimore, Md., has been formed to make automobile tires. No plant as yet has been selected. The name of the tire will be Wil-Lox. The capital stock of the company is $200,000. The officers of the company are G. W. Hahbersett, president; H. M. Rever, secretary-treasurer; A. S. Mauk, vice-president and general manager.

Timken Roller to Build in Canton—The Timken Roller Bearing Co. announces that a new addition, which will give employment to 200 men, will be built by the company on Deuher Avenue, Canton, Ohio. This announcement was made following action by the city council granting the company permission to use a portion of Nineteenth Street. When it was reported that the new addition would be erected at Detroit, where another branch of the company is located, the city council granted the permission desired.

Watertown Co. to Make Tractors—The John Dornfeld Co., Watertown, Wis., machine shop, structural iron, boiler and tank works, has entered into a contract with the Brillion Implement Mfg. Co., gasoline engines, Brillion, Wis., for the joint manufacture of a general utility farm tractor and truck. The Brillion company will manufacture the engines and the Watertown firm the chassis complete. The product will be distributed and marketed from Watertown. The tractor is a Brillion design and arranged for manifold purposes. About seventy-five men will be added to the Dornfeld payroll at once.

Janesville Workmen to Build Tractors—Union workingmen of Janesville, Wis., seeing the possibilities of the gas tractor business, have organized the Janesville Tractor & Engine Co., Janesville, Wis., to engage in the manufacture of a general utility tractor for agricultural purposes.

The Week in the Industry

Smith Goes to Edison—G. D. Smith, for the past two years supervisor of agencies for the General Vehicle Co., Inc., has been appointed special assistant to H. G. Thompson, vice-president and general sales manager, Edison Storage Battery Co. Mr. Smith will make his headquarters at the factory and main office, Orange, N. J.

Hupp Appoints New District Managers J. G. Painter and W. J. Walker have been appointed district managers by the Hupp Motor Car Corp., Detroit. Mr. Painter has had charge of the technical service department at the Hupp factory. He will have charge of the important territory of Ohio, Michigan, Northern Indiana and a portion of West Virginia. Mr. Walker, with headquarters in Winnipeg, will cover Alberta, Manitoba, Saskatchewan and Western Ontario.

Dealers

Wis. News Items—W. L. McLaughlin, Algoma, Wis., operating under the name of Algoma Tire Repair Co., opened a vulcanizing and tire store at Steele and Fourth Streets on March 1.

Schueler Bros., 247-249 Milwaukee Street, Milwaukee, operating a large painting and trimming shop, have been appointed distributers of Hood and Puritan tires for the State of Wisconsin.

The K. W. Battery Co., Milwaukee, has established a factory and repair shop for storage batteries at 1702 North Avenue, Milwaukee. The firm is composed of F. Kruschka, president; C. Jurss, secretary, and C. Weidler, treasurer. The company will manufacture batteries as well as rebuild and repair cells. An elaborate recharging outfit has been installed.

Harry Newman, Inc., 701-707 Grand Avenue, Milwaukee, distributer of the Chalmers in Wisconsin, upper Michigan and adjacent territory, announces the addition of two former Studebaker men to his Milwaukee staff, viz.: H. H. Batcheller, formerly of the Chicago Studebaker branch, and L. S. DeLand, since 1910 sales manager of the Studebaker for Wisconsin in Milwaukee. Both men will travel through the Newman territory and co-operate with Chalmers dealers.

The Wisconsin Aluminum Foundry Co., Sixteenth and Franklin Streets, Manitowoc, Wis., is having plans prepared for a 75 by 145 ft. addition, to be used for foundry and machine shop purposes. The present plant was erected only three years. The business for 1915 showed an increase of more than 50 per cent.

Motor Men in New Roles

New Men for Vim Truck—The Vim Motor Truck Co., Philadelphia, Pa., has added T. E. Cathcart, W. L. Kroneberger and Howard Hewitt to its force. Mr. Cathcart was formerly with the standard Roller Bearing Co. in charge of sales. Mr. Kroneberger was with the Curtis Publishing Co. in its circulation department and Mr. Hewitt was factory service manager of the Morgan Dean Rapley Co., Hamilton, Ont.

Daniels Heads Springfield Chalmers—The Chalmers Motor Co. of Illinois has leased the building at 408-412 East Monroe Street, Springfield, Ill., and makes this the distributing center for central Illinois. H. B. Daniels has been engaged as resident sales manager and will have a staff of assistants. The plant just leased will be enlarged and improved for sales and storage purposes.

Chapman Resigns—H. O. Chapman, in charge of the Packard agency at Dubuque, Iowa, has resigned to become sales manager for the L. J. Theiss Co., Rockford, Ill.

Duggan Takes on Dort—The Dort distributing agency for Colorado and adjacent territory is now in charge of George A. Duggan, located temporarily at 1528 Broadway, Denver. C. Mark Hanna, formerly associated with him, is his sales manager.

Johnson Returns to Toronto—D. F. Johnson, former Canadian and European agent of the Stewart-Warner Speedometer Corp., has returned to Toronto from San Francisco, where he had charge of the coast business of the company. The company will establish service stations throughout Canada and has appointed Johnson director and sole Canadian distributor of the Stewart-Warner products. The head office of the chain of service stations will be the Toronto depot at 486 Yonge Street.

Allen Goes to Detroit—C. M. Allen has left for Detroit in the interest of promoting the sale of the Heath carbureter, manufactured by the M. K. Bowman-Edson Co., New York City.

Pollock Detroit Rep.—P. J. Pollock has been appointed a sales representative of the Detroiter Motor Car Co., Detroit, Mich. He will travel through Ohio.

Ranney Columbus Firestone Sales Mgr.—G. E. Ranney, formerly of the Chicago branch, has been made manager of the Columbus branch of the Firestone Tire & Rubber Co., to fill the vacancy caused by the promotion of G. E. Richards to the management of the Pittsburgh branch.

Sehl Joins Studebaker—J. P. Sehl, who was commercial body designer of the Pierce-Arrow Motor Car Co., Buffalo, is now a member of the body-designing department of the Studebaker Corp., Detroit, Mich.

Shafer Takes Standard in Los Angeles—C. C. Shafer has been appointed southern California and Arizona distributer of the Standard "8" line with headquarters in Los Angeles. The agency is housed at Eleventh and Olive Streets recently vacated by the Goodrich branch which is now in the seven-story Goodrich building on South Broadway.

Dealers

Burd Opens New Offices—The Burd High Compression Ring Co., Rockford, Ill., announces the opening of two additional sales offices during the past week. E. C. Fish was appointed manager of the new Rochester office, which is located at 558 Lyell Avenue, and the new Pittsburg office will be under the management of E. J. McClees at 904 East End Trust Bldg. H. F. Belcher, who has been working out of the Chicago office of the company for some time, has been transferred to the Peoria, Ill., territory. L. G. Rasmussen, for a number of years with the Woods Vehicle Co., has joined the selling organization of the Burd company, and will be attached to the Chicago office, covering the Northern Illinois territory outside of Cook County.

Denver News Items—The Chandler Auto Co. is the name of a new Colorado distributing agency for the Chandler just opened at 1518 Broadway, Denver.

Mulnix & Rarie, Colorado and Wyoming distributors for the Grant, have bought out the Pathfinder distributing agency from the Charles F. Cole Corp. and moved from 17 East Colfax Avenue, Denver, into the Cole quarters at East Colfax Avenue and Lincoln Street.

The J. S. Morrison Auto Co., 1528 Broadway, Denver, has turned over the Dort to another distributing agent and is now handling the Oakland exclusively.

The Federal Rubber Mfg. Co. has discontinued its Denver branch, and arrangements have been completed with the Federal Rubber Tire Works Co., a Denver concern, to act as Federal distributor for Colorado and adjacent territory. The president of the new distributing firm is E. R. Cumbe.

UNIV. OF MICH. LIBRARY

The AUTOMOBILE

Vol. XXXIV,
No. 11

NEW YORK, MARCH 16, 1916

Ten cents a copy
Three dollars a year

That Dirty, Grimy Hood

of yours can be made just like new—you can easily do it yourself and save the cost of refinishing—all you need is Johnson's Cleaner and Johnson's Prepared Wax.

JOHNSON'S CLEANER

entirely removes all stains, discolorations, scum, road-oil, tar and grease from body, hood and fenders. Even those spots that are ground in—mud freckles—and surface scratches which you thought were permanent—will disappear like magic under Johnson's Cleaner. And it doesn't injure or scratch the varnish—simply cleans and prepares it for a polish with Johnson's Prepared Wax. This treatment will keep your car like new indefinitely.

Read What Users Say

"Far superior to oil polishes."—*H. Y. Waterhouse, 525 Boylston St., Boston, Mass.*

"You would think the car was newly enameled."—*Harry C. Freeman, Box 182, Port Jefferson Sta., L. I., N. Y.*

"The Cleaner and Wax made it look like a new car."—*Clayton Wren, Munday, Texas.*

"It is certainly wonderful stuff."—*Dr. W. J. Berringer, Council Bluffs, Ia.*

"Saved me quite a sum of money. It worked wonders on that car."—*James M. Christian, 115 Rutledge Ave., E. Orange, N.J.*

"The Cleaner has taken off spots from my car that I thought would never come off."—*John B. Rozzini, 1897 Summit Ave., St. Paul, Minn.*

"I was surprised at the cleansing and polishing powers of your products."—*Oral Pirkey, Balker Apt. 8, Vancouver, Wash.*

S. C. JOHNSON & SON, Racine, Wis.

I enclose 10c for a trial can each of Johnson's Cleaner and Johnson's Prepared Wax.

The Automobile

Custom-Built Bodies Grow in Popularity

This Branch of the Automobile Industry, Until Recently Comparatively Insignificant, Promises Soon To Assume National Proportions

By Donald McLeod Lay

ONE of the most important tendencies brought out at the recent national automobile shows is a strong movement toward body improvement and development, as evidenced by the increasing demand for custom designs. At these shows there were exhibited many more special bodies, or constructions in which the aim was to get away from the hidebound conventionality of the stock type, than were on display at any show of recent years. These attempts to strike a note of individuality, while preserving the best features of modern coachmaking, may be characterized as the forerunners of a more widespread adoption of the ideas which prompted their creation.

The art of the coachbuilder, far from being on the decline, as some of the devotees of the "good old days" would have us believe, is still a long way from the attainment of its highest development. But it is not the further refinement of the horse-drawn vehicle which will be responsible for its progress in the future. The coachbuilder's interest in this field of his work will shrink to comparatively small proportions beside the more attractive opportunities in the increasing demand for smart, distinctive and comfortable automobile bodies.

A typical custom-built body. This is a convertible roadster-coupé mounted on a Locomobile chassis

There is a large class in the United States that prides itself upon its fastidious tastes in every phase of existence. It aims to be distinctive, individual, and to have everything in life to correspond. Clothes must be smart, elegant and well tailored; homes must be artistic backgrounds for personalities; food must be dainty and delicately prepared and must represent the most exquisite dishes money can buy; and so throughout the establishments, everything must be in keeping with these standards.

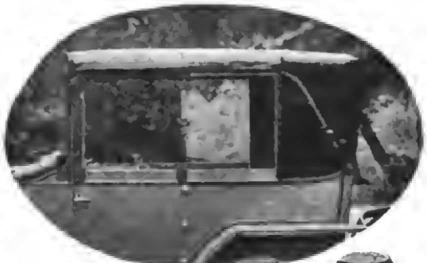
Want Something Different

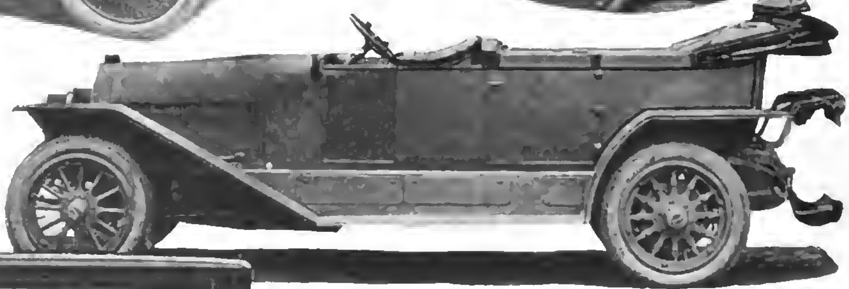
In other words, people of this class are not usually satisfied to accept the stock bodies sold by the American automobile manufacturer. They want something different, and as the number of cars in use increases each year, so will this demand for specially-designed and built bodies grow larger and larger as more car purchasers adopt the custom construction.

There are thousands of people throughout the country who, though not rolling in riches, are sufficiently prosperous to be able to afford the additional expense entailed by satisfying their sense of the fitness of things as re-

Some Custom Designs of

A four-passenger sporting body with Victoria top mounted on Lancia chassis. Note oval fenders, absence of running board and mounting of spare wheel



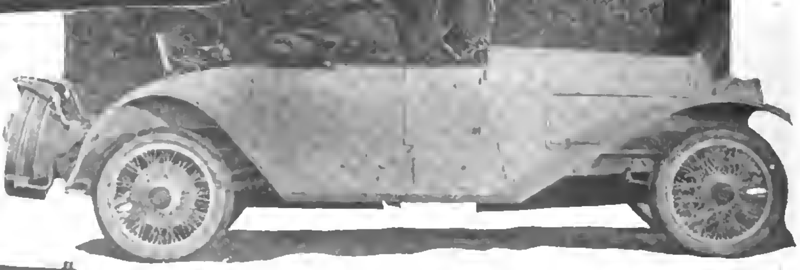


A special collapsible design produced by Locomobile. Below it is illustrated with top and sides folded and above with the top raised although the side windows are lowered

A permanent top product by Locomobile which may be quickly converted into an open body by lowering the windows

A four-passenger roadster with folding rear seat mounted on an Owen Magnetic chassis.

View of the body outlines and seating arrangement in a special Locomobile job exhibited at the National shows



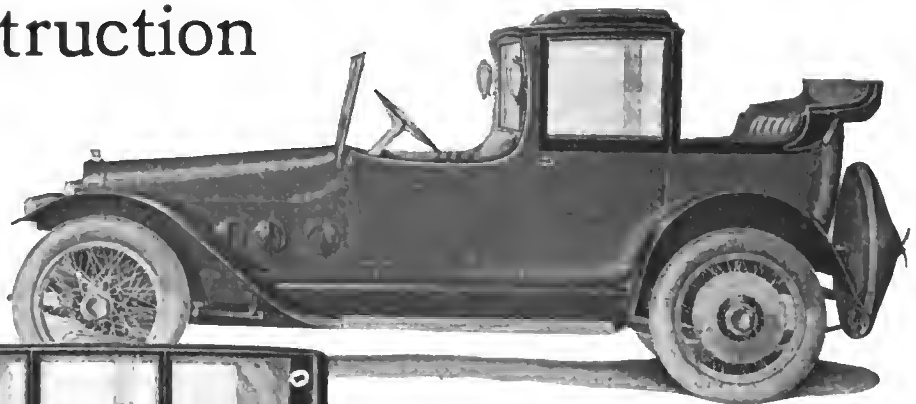
Another excellent example by Locomobile of the latest four-passenger body construction in which the rear seat disappears in the turtle back

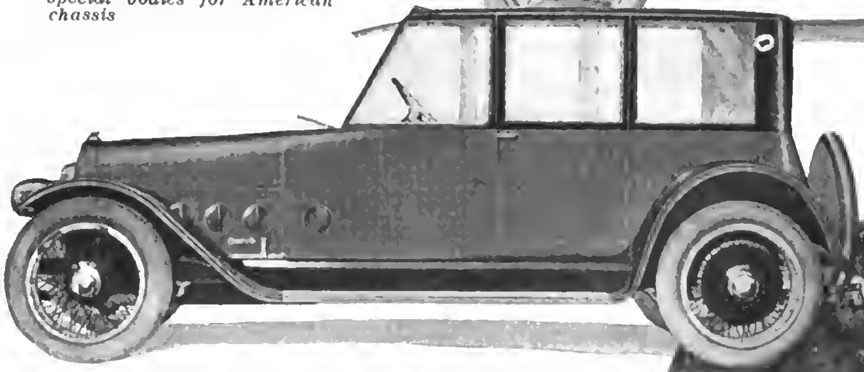
Aquatic touring body by Holbrook. The general lines are like those of a boat. It is mounted on a DeDion-Bouton chassis

Distinctive Construction

At the right is a special brougham with landaulet top designed by C. T. Silver for an Overland, Willys-Knight or Peerless chassis

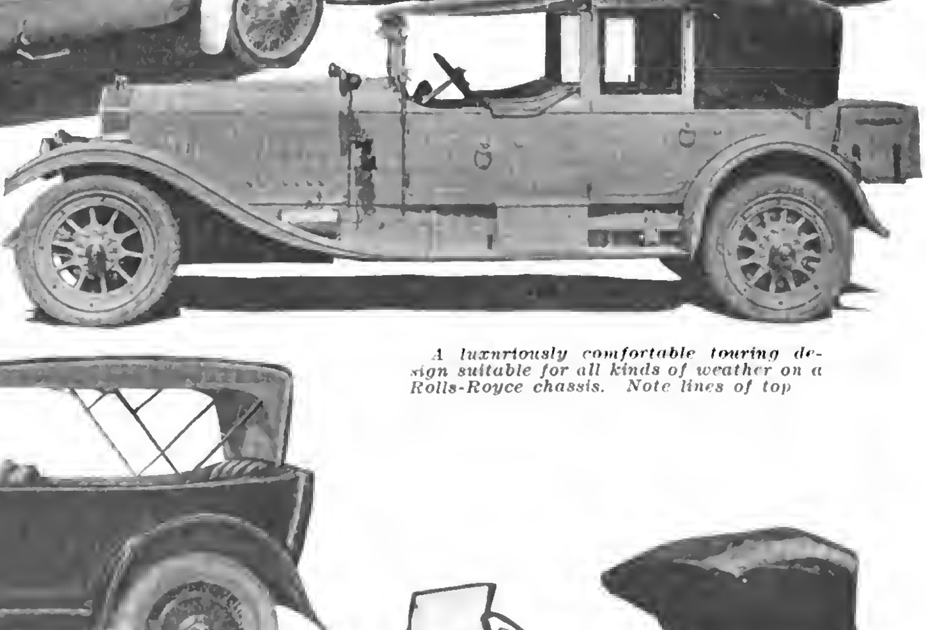
Below is a four-passenger sedan designed by Mr. Silver for the same chassis. Mr. Silver represents these cars in the Metropolitan district and is a pioneer in designing special bodies for American chassis





Below is illustrated Mr. Silver's masterpiece, the Silver Bird, a design in which the boat idea is carried to the extreme, every detail from the anchor bumper to the nickel propeller at the rear being in keeping

A torpedo-style four-passenger sporting type with folding rear seat and two windshields mounted on a Singer chassis



A luxuriously comfortable touring design suitable for all kinds of weather on a Rolls-Royce chassis. Note lines of top

A streamline Bender & Robinson design on a Singer chassis. Note the extremely smooth lines which are unimpaired when the top is down, as it folds into the body

An attractive streamline touring body with Victoria top designed by Holbrook. It is mounted on a Cadillac chassis gards the comfort and appearance of their cars. To-day most of them take the stock bodies without comment because they have had no opportunity of seeing what the expert coachmaker can do to express individual ideas and tastes. But when the wave of custom body design, which now seems to be gathering momentum in the East, begins to spread over the land, these people will be the first to take advantage of the new trend.

New York the Fashion Center

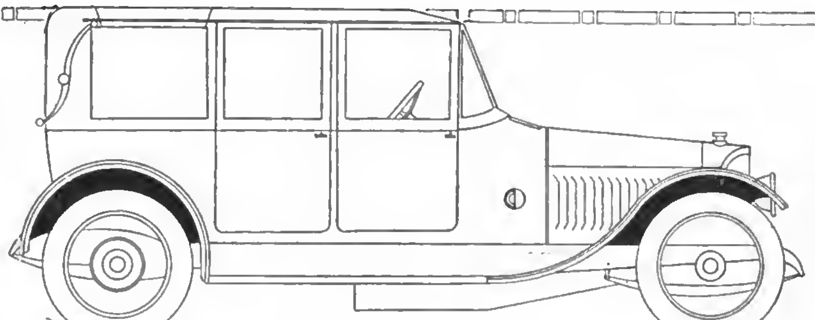
Of course New York City is the great center for the custom body trade in America to-day. Ever since the first days of the automobile industry, when the majority of the cars in New York were of foreign construction, European influence has been more strongly felt in that city than in any other section of the country. It was not many years before the wealthy families who were recognized as the leaders of fashion began to import chassis either separate or fitted with a specially-built body, designed to order by one of the celebrated coachmakers of Paris or London. This vogue, however, grew but slowly, because an imported chassis and body were not within the reach of many, even of the more prosperous classes, in those days. More recently, of course, foreign-built cars and bodies have become less a rarity then formerly, but it was apparently some time before anyone thought an American-built chassis was worthy of carrying a custom body.

Still, the fact that special automobile bodies were a distinction possessed only by members of the Four Hundred, set the fashion for the élite, the would-be-élite, social climbers, nouveau riches, etc. All set about procuring something distinctive, striking and frequently conspicuous, when the purchaser's taste was not as highly developed as it might be. Most of them, of course, bought European-made chassis on which to mount the new body, but some were not disposed to go to such expense and invested in an American machine, hoping that the body would disguise it sufficiently to prevent it being recognized as a domestic product.

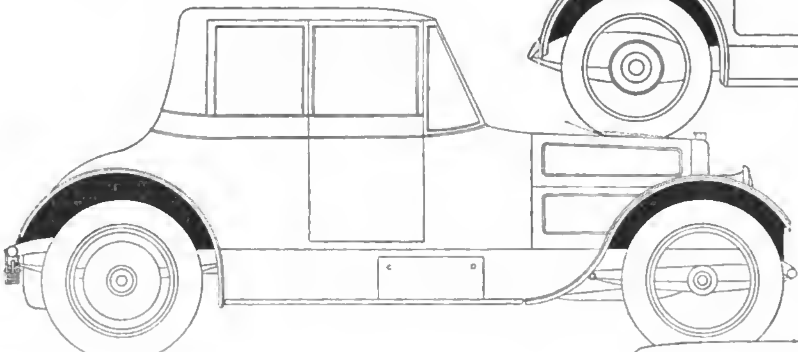
Thus the custom-designed body increased in popularity year by year, the types built by New York coachmakers to the orders of customers ranging from the most unpractical and freakish offsprings of an untrained imagination to the most comfortable, luxurious and highly refined examples of the art ever turned out. More and more people saw these special creations running about the streets or along country roads and became imbued with the desire to own cars having the same distinctive qualities. The most enterprising dealers recognized this growing demand and proceeded to prepare special designs applicable to the chassis of the cars they handled, and thus was the American custom body industry inaugurated.

To-day the number of firms designing and building bodies especially for the custom trade is growing almost from day to day. New concerns are springing up in all parts of New York City and neighboring districts, while the old established coachmakers find that the equine phase of their business has

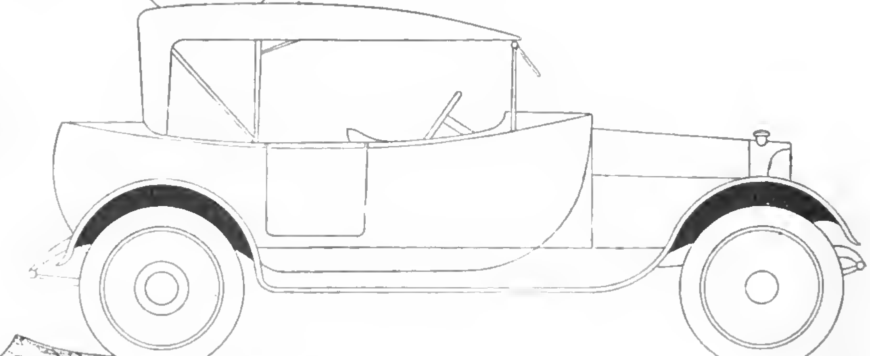
All the bodies illustrated on these two pages, 488 and 489, are reproductions from drawings of special custom designs by the George P. Harvey Co., New York City

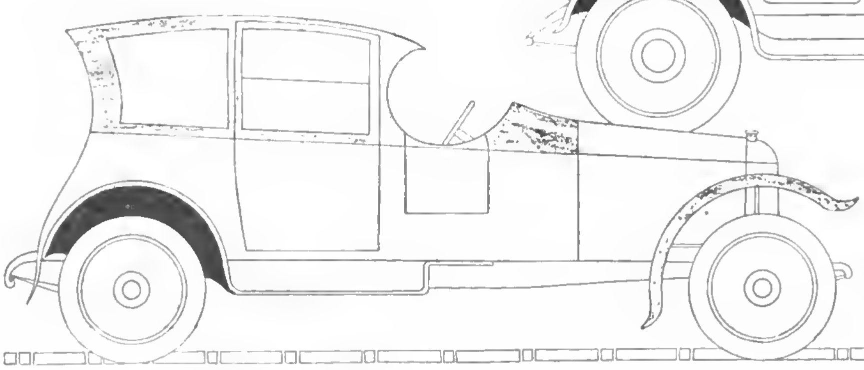


Above is what may be termed a landau-sedan, the top folding neatly down at the rear. This design was based on a customer's suggestion

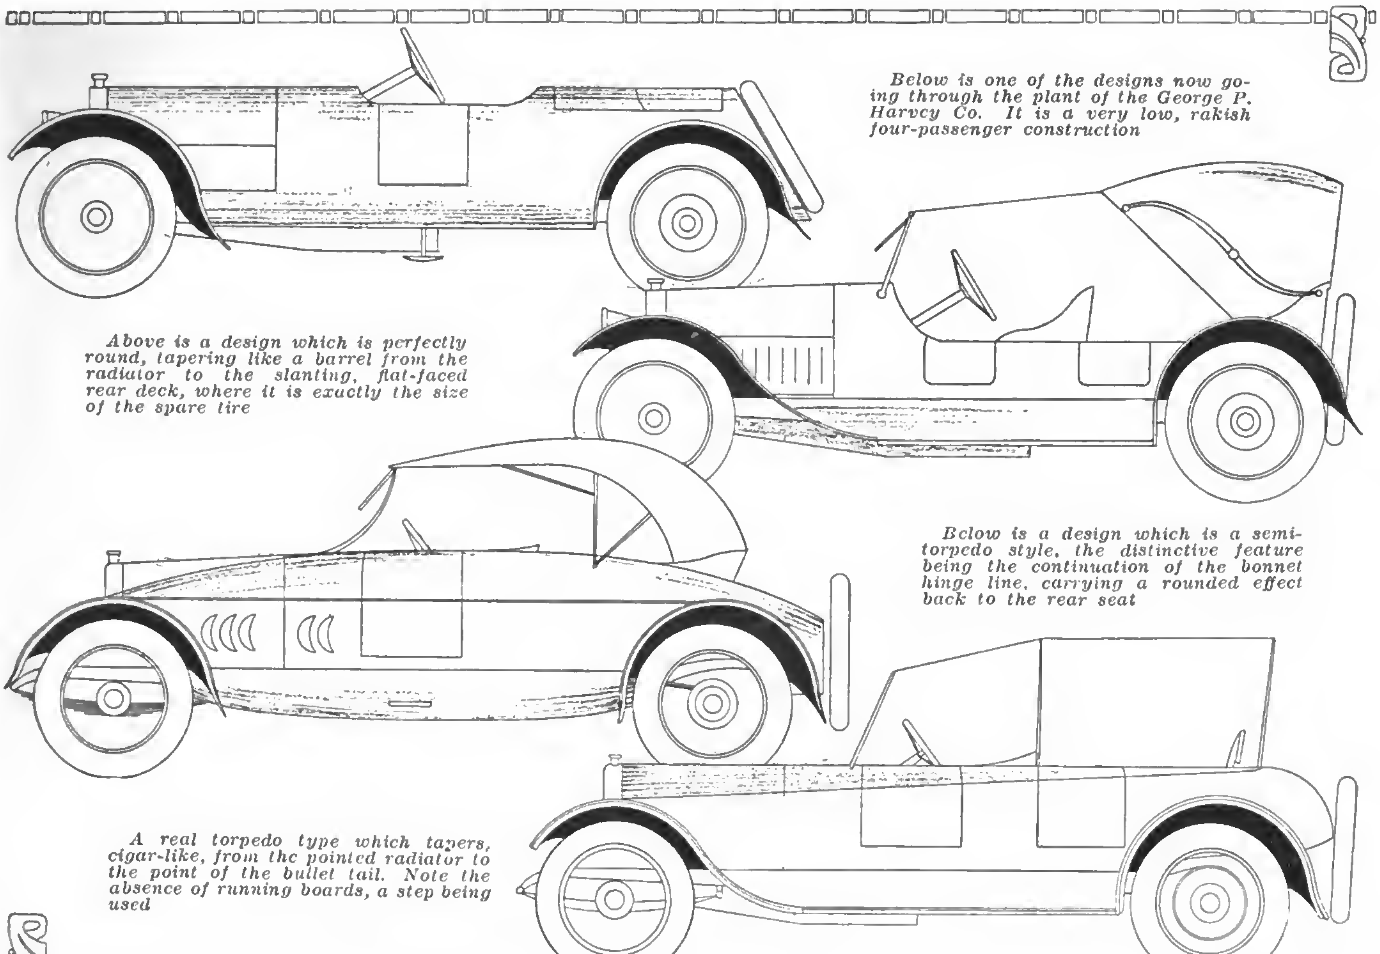


A coupé of unusual and distinctive lines. Note the slope of the top which merges gradually into the rear deck and the triangular window beneath the slanting windshield





Above and at the left are two designs which might be classified as freaks. The boat body was built to meet the fancy of a New York theatrical manager and the job at the left was conceived merely with the idea of attracting attention



Below is one of the designs now going through the plant of the George P. Harvey Co. It is a very low, rakish four-passenger construction

Above is a design which is perfectly round, tapering like a barrel from the radiator to the slanting, flat-faced rear deck, where it is exactly the size of the spare tire

Below is a design which is a semi-torpedo style, the distinctive feature being the continuation of the bonnet hinge line, carrying a rounded effect back to the rear seat

A real torpedo type which tapers, cigar-like, from the pointed radiator to the point of the bullet tail. Note the absence of running boards, a step being used

dwindled to almost insignificant proportions, the bulk of their trade now being in special bodies for automobiles. And all these companies are having no difficulty in obtaining business; in fact, most of them have more work on hand than they will be able to complete for some time. It looks as though the coachbuilder has come into his own, so far as the eastern section of the country is concerned.

New York is the great fashion center for body design just as it was in the early days of the industry when the only basis for these fashions was furnished by the products of European designers. The growing vogue of the custom-built body is bound to spread to other cities; in some of them, Boston, Chicago and Philadelphia for example, its influence has already been felt, and during the coming season it should become more and more a factor with the car-buying public, not only of the large cities but also of the smaller communities. Even the small towns of but a few thousand inhabitants each have several families sufficiently opulent to be attracted successfully by the advantages and attention-compelling qualities of special bodies for their cars.

A National Field

This opens up a vast field which should be developed during the coming years. The new ideas and the refinements in material, construction and design, brought out by the demand for the unusual, the beautiful and the durable in body work are bound to produce a marked effect on the stock body which the American automobile manufacturer will furnish with his car. It may be that more manufacturers will establish custom body departments as some of the high-priced car manufacturers have already done. It may be that stock bodies will be developed which may be changed readily in almost every respect to meet the requirements of the car buyer. The possibilities of the changes which may be thus indirectly brought about are so boundless that speculation is useless.

From present indications it would seem that the American custom body trade is graduating from a mere local occupation of negligible importance to a branch of the great automobile industry which will be national in scope, and involving thousands of men and immense capital. This will be the logical result of the formative conditions prevailing during recent years and at the present time. The demand is there, and where there is demand supply is usually forthcoming. The accelerated activity in the custom body field in New York City is significant of what may be expected, though probably in a lesser degree, first in the other large centers of population and later in the smaller communities.

Car dealers, particularly the more progressive, are featuring the attractions they are able to offer in the way of furnishing their customers with special bodies which will incorporate any of the car-buyers' ideas regarding appearance, comfort and construction, although most of the dealers are far-sighted enough to point out the impractical side of any suggestion which would be likely to result in ultimate dissatisfaction to the purchaser. Many employ designers especially to carry out the ideas of prospects desiring special bodies while others maintain close relations with coachbuilders, permitting them to furnish everything from drawings to the complete body.

Illustrative of the value of suggestions made by car-buyers to the body builders, and frequently these car-buyers know practically nothing of automobile construction, one coachmaker declares that he secures far more original and practical or near-practical ideas from his customers than from all of his competitors combined. And all report that customers are more numerous than ever before, because of increased prosperity and a wider recognition of custom bodies.

Analyzing Engine Cooling

An Accurate Determination of the Factors Affecting Cylinder Cooling and a Quantitative Examination of Air and Water Cooling Comparatively

Results of F. W. Lanchester's Researches Reviewed by A. Ludlow Clayden

PROBABLY no automobile engineer in the world has a greater reputation for originality than F. W. Lanchester of England. Mr. Lanchester was one of the first people to build an automobile in England and adopted an air-cooled engine. After using this for some years difficulties commenced, and a water-cooled motor was substituted. For the last five or six years Mr. Lanchester has not been connected actively with his original company, but has been doing consulting engineering and has given much time to original research.

In December, 1915, he presented to the British Institution of Automobile Engineers a paper dealing with cylinder cooling both by air and by water. This paper is of immense length, containing ample matter for a fair sized text book, and in it the mathematics of the subject are considered in a clear and fairly simple manner. The object of the whole investigation was to determine the relative advantages of air and water cooling in absolute terms.

Mr. Lanchester showed and proved that; weight being of primary importance in the automobile and more strongly still in the aeroplane, air cooling is the lighter system up to a certain cylinder size above which it ceases to save weight. The exact quantities of water and air to give theoretically correct cooling are determined in the paper and an examination made afterward to gage the relative weights.

Anyone deeply interested in the design of light engines could not fail to find this paper of real value, but it is much too long for it to be possible to reproduce it in THE AUTOMOBILE. In the following pages just the highest spots are brought out, and the mathematical proofs are omitted.

All Engines Air Cooled

In the paper it was first pointed out that automobile engines are all air cooled since the water in the ordinary cooling system merely acts as a carrier which can transfer the heat to the atmosphere. In pointing out the importance of having the greatest possible surface in a radiator in proportion to the volume of water carried, the author stated that a ¾ in. pipe will contain 1 lb. of water per square foot of surface, whereas in a properly designed honeycomb radiator the weight of water need not exceed 2 or 3 oz. per square foot surface. The object of emphasizing this point was to bring home the fact that the purpose of the radiator is to transfer to the air the heat which it is necessary to dissipate. The surface of the tubes in a radiator acts in precisely the same way as the surface of the gills on an air-cooled cylinder and the purpose of the water is to transfer heat from the small area of cylinder wall to a much larger area in the radiator, since the water is only a carrier it is obvious that the larger the radiator surface per pound of water the less water shall be required to insure effective cooling. We may now proceed to quote from the paper concerning Mr. Lanchester's first design for an air cooling engine.

Complementary to the problems associated with water circulation the automobile constructor from the earliest time has had to face the question of the circulation or free flow of the air.

The most prevalent defect or difficulty to-day, as concerning the flow of air, is the restriction commonly experienced in getting the air away from the bonnet. Thus large apertures beneath are inadmissible as admitting dirt and mud in quantity; ventage in the top is out of the question, and the rear is choked with mechanism. Louvres at the sides offer an obvious solution, but these are generally speaking banned as unpopular.

When we turn from cooling by water circulation to direct air cooling we encounter at once the main difficulties of the problem in an aggravated form. The motor cycle, especially the bicycle, is to some extent under the same conditions as the flying machine—it always operates between certain maximum and minimum speed limits, also the motor is rarely or never required to run with the machine standing. The motor cycle, however, is not so favorably situated as the flying machine inasmuch as its cooling may be seriously interfered with by a following wind.

As regards the air cooling of the full weight motor car, the author believes he can claim to have been responsible (in England at least) for the only serious attempt at air cooling on a commercial scale, namely in the Lanchester 10 and 16 hp. cars manufactured between the years 1900 and 1904.

In the design of his first air-cooled car, the author made very careful calculations of the jacket conductivity and surface required, but at that date, 1895, he had not at his disposal a reliable estimate of the total heat to be carried away, neither had he developed at that time the theory of surface cooling on the lines of his more recent work.

In the first experimental engine the gills were of copper, cast with a small percentage of zinc in order to secure fluidity; the conductivity was carefully calculated. The data for the calculation of the surface required were non-existent, and in this respect also the author had to rely upon some rough experiments conducted on his own account. Ultimately the total surface was regulated by the fact that it was found impossible with cast copper gills to get too much; the gills were therefore cast as separate plates as thin as possible and were spaced 5/16 in. pitch; the necessary air-way was calculated on the same basis as in the present paper. In other words, the total cross section of air-way in the jacket was designed to pass an ample volume of air under the available fan pressure; the fan was of centrifugal type formed by vanes on the flywheel rim. It should be noted that the centrifugal fan acted by pressure, the air being collected in an expanding conduit and delivered to the jacket at a pressure of about 1 in. water gage above atmosphere.

Certain improvements were effected in the jacket detail; spun or pressed sheet copper plates of light gage and pitched closely were substituted for copper castings. Cast aluminum gills were also tried with apparently equal success. Data as to these jackets are given in Figs. 1 and 2. Fig. 1 is a section of the jacket in which the gills are of cast aluminum, and Fig. 2 the alternative construction, in which 24 s.w.g. sheet copper is employed. In the two arrangements discussed, the author considers he had reached a high standard of efficiency in direct air cooling; the difficulties seemed to be virtually conquered. Unfortunately, in remodeling the design with a view to convenience in manufacture, concessions were made in the cooling arrangements in order to facilitate production. Thus the pressure fan was found to be very difficult to embody in the design, and eventually a suction fan was substituted. Again difficulties arose in the design of a cylinder and valve gear which would permit of the attachment of the copper gills, and probably the author committed an error of judgment in allowing himself to employ cast iron, that is to say, to substitute motorcycle practice for the practice which he had developed himself and which was undoubtedly far more efficient. The type and general arrangement of the centrifugal fans with friction drive as fitted in the later models (the 10 hp. and 16 hp.) are clearly shown in Fig. 3; this figure is self-explanatory, a comparison with Figs. 1 and 2 will show the extent of the sacrifice made to facilitate manufacture.

Suction Fan Bad

The suction type of fan also is bad; firstly, it is far less efficient, owing to the fact that no use is made of the velocity of the air leaving the fan. Secondly, as the jacket gets hotter the fan pressure gets less owing to the lower density of the heated air. When the first few cars were put on the road with these modifications a tendency to overheat was at once evident and it became necessary to greatly increase the draught. To this end frictionally driven fans were fitted in the place of the fan flywheel, and although by this means the cooling was rendered possible, the consumption of power became serious.

Having thus reviewed the subject in a general way, the author next proceeded to discuss the quantity of heat which it is necessary to dissipate.

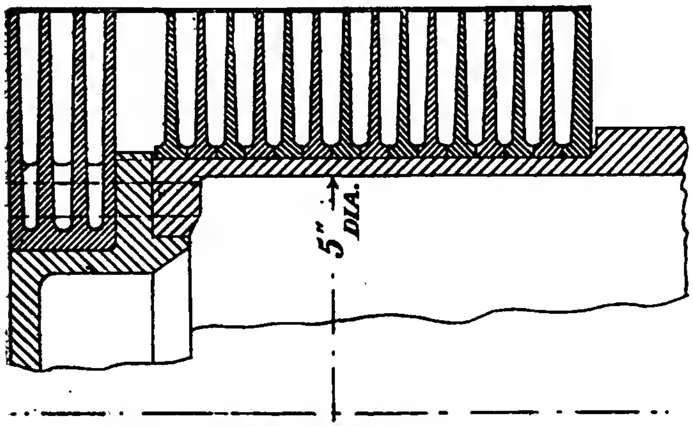


Fig. 1—Air cooled cylinder with cast aluminum gills

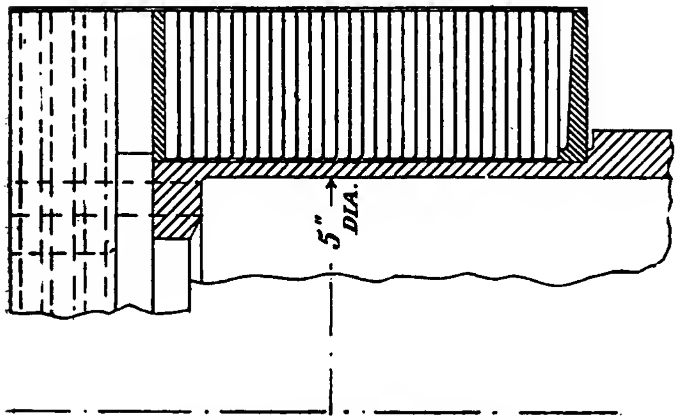

Fig. 2—Cylinder with sheet copper gills

From the practical side, modern experiment appears to show that the total jacket loss for any given engine:

(1) Is not (at full load) constant with regard to revolution speed, but increases as the speed increases but not in like ratio. Thus it is neither constant as an *amount of heat* lost nor as a *percentage of the total fuel heat*, it is something between the two. It may be accounted for approximately on the basis of a portion being a constant loss, and the remaining portion a constant percentage of the total heat. The heat loss may be represented by a diagram as in Fig. 4. This diagram has no pretensions to minute accuracy since much depends upon the design; it does, however, represent as near the truth as can at present be expressed in general terms. The upper of the two diagrams, Fig. 4a, gives the relative jacket heat loss for variations of piston speed. The lower, Fig. 4b, gives the jacket loss expressed as a percentage of the total heat value of the fuel. Abscissæ give the *cylinder diameter × mean piston velocity;* the units are the foot and the second.

(2) The jacket heat loss within ordinary limits is independent of the compression ratio.

(3) The jacket heat loss appears to vary approximately as the square of the strength of the mixture, or the heat loss expressed as a *percentage* varies directly as the strength.

(4) In an engine governed by throttle the *percentage* jacket heat loss is greater at low power than at full load.

(5) If the timing of the ignition be varied the *percentage* heat loss is greater when the timing is early than when late. Expressed, however, *in terms of the power developed,* the loss to the jacket is least when the ignition timing is *a little later* than that of maximum torque. This aspect of the subject is important; the question, in the case of an engine tending to overheat, is commonly the performance of a given task. Thus an automobile is less liable to boil its water when hill climbing, if the ignition is *very slightly* late.

Rule for Heat Loss

Thus we have the following rule for the expression of the heat loss:

The mechanical equivalent of the heat lost to the walls of the cylinder and combustion space in an internal combustion engine of ordinary type, may be expressed as equal to one-tenth of the mechanical equivalent of the heat value of the fuel consumed, plus 1 hp. for every inch of cylinder diameter.

The part of the heat loss which is a constant percentage of the total (*i.e.* mainly that lost as internal radiation) may alternatively be expressed as a percentage of the engine power, since this bears a fairly constant proportion to the total: it is roughly equal to one-half to one-third of the indicated horsepower, according as the thermal efficiency is about 20 per cent or 30 per cent.

Where a multi-cylinder motor is in question the diameter measurement will be the sum of the diameters of all the cylinders in inches.

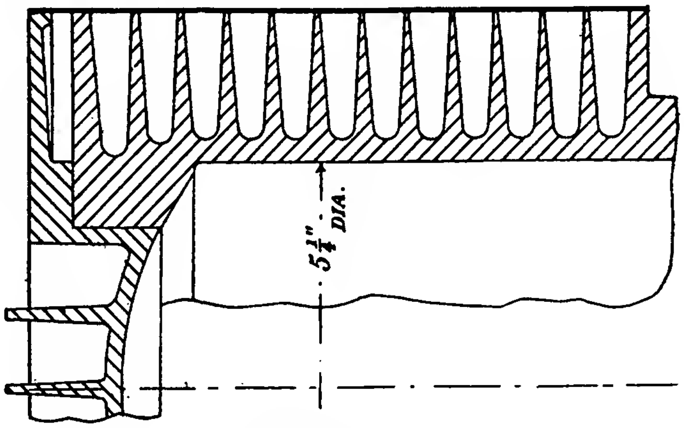

Fig. 3—Cylinder with cast iron gills

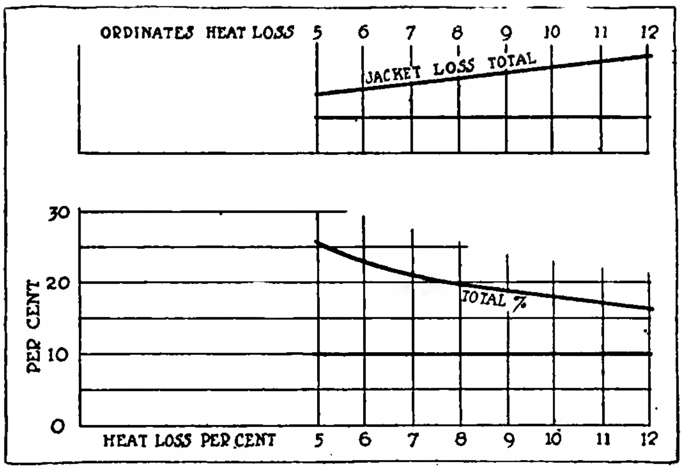

Diagrammatic Heat Loss Curves

It must be clearly understood that the foregoing does not include the heat discarded beyond the exhaust port; heat imparted to the exhaust pipe, if it is to be provided for in the jacket system, must be counted as extra.

It is also important to make it clear that the "radiation losses" discussed in the present section are not the same radiation losses as those sometimes referred to in works on the subject. The losses with which we have been concerned are those due to the radiation *from* the incandescent gases *to* the cylinder walls, whereas radiation losses are frequently spoken of as the radiation *outward* from the piston, jacket, and other portions of the engine, more especially as affecting the heat account when that is determined by experiment.

It will be found on applying the rule to actual examples that it frequently gives results slightly above those measured; possibly the allowance per inch of cylinder diameter is somewhat higher than it should be; however, the round figure 1 hp. per inch diameter is quite near enough for practical purposes.

Cases also occur in which the measured jacket heat is considerably greater than given by the rule, but in all these cases it will be found that exhaust heat, that is to say heat from the exhaust pipe, port, etc., is being included in the jacket loss. Either the water jacket extends around the valve box and branch, or a great deal of heat is communicated from the exhaust passages to the water jacket by conduction.

It will be shown later that when we come to the consideration of the problem of direct air cooling it is convenient to express the heat passing into the cylinder walls in terms of either *heat units* or *horsepower per unit area.*

Thus, for example, in the case of a cylinder 4 in. diameter by 6 in. stroke developing 12 hp. on a consumption of 8 lbs. gasoline per hour, the waste heat will be the equivalent of $6 + 4 = 10$ hp. Now the cylinder and compression space wall of such a cylinder would total up to about 0.75 of a square foot, so that we may express the heat loss as having a mean value of 13 *hp. per square foot* or 2.5 *calories per square centimeter per second.* The distribution of the heat loss, however, varies considerably, it is far higher in and near the combustion space than in the cylinder wall proper. The continuation of this discussion takes its place later in the paper.

Conduction Through Cylinder Wall

The passage of heat through the cylinder wall is controlled by the conductivity of the latter. The scientific basis by which the conductivity of a material is defined is the measure of the parallel flow of heat through a given sectional area of the substance for some stated temperature gradient. Thus employing C.G.S. units the area of cross section taken is one square centimeter, the gradient is 1 deg. C. per centimeter, and the quantity of heat transmitted, in (gram) calories per second, is the measure of conductivity. In other words, if we imagine a one centimeter cube of metal, of which two opposite faces are maintained at a difference of temperature of 1 deg. C., then if the amount of heat flowing through the cube under these conditions is sufficient to raise 1 gram of water 1 deg. C. per second, the conductivity of the said metal will be unity. This is approximately the conductivity of pure copper. The conductivity of copper and of other of the metals commonly emloyed by the engineer is as below:

Copper	0.9 to 1.0
Aluminum	0.5
Brass	0.25 to 0.3
Iron or Steel	0.15 to 0.2
Cast Iron	0.11 to 0.12

The conductivity of heat through the cylinder walls is one of the factors by which the maximum size of cylinder which can be employed (in an internal combustion engine) is ultimately limited. For a given number of heat units per unit area transmitted to the cylinder walls it is clear that the *temperature gradient* will be constant, and thus the difference of temperature between the inside and the outside of the wall of the cylinder and combustion space will vary directly as the thickness. The result of this is that, whatever the material employed may be, sooner or later a limit of thickness is reached at which the stresses set up in the material due to inequality of expansion result in its disruption.

If the relative conditions are to remain constant for variations of size, the conductivity of the material needs to be increased in proportion to the linear size. There is no way by which this can be practically effected.

As an example, the temperature gradient within the cylinder wall based on the mean value of heat flux above given (= 2.5 calories per square centimeter per second) may be given. Assuming the conductivity of cast iron $k = 0.11$, we have, *gradient* $= 2.5/0.11 = 23°$ C. per centimeter.

(b) *Conduction by Gills; and*

(c) *Heat Transference from Gills to Air.*

In a direct air-cooled engine the function of the gills is to carry the heat from the outside of the walls of the cylinder and combustion space and convey it by conduction radially outward, and eventually to give it up to the surrounding air. Thus the surface of the gills requires to be of sufficient area to dispose of the heat to the air, and the section through the gills, that is to say, the sectional area of metal taken normal to the heat flow, must be sufficient to transfer the said heat by conduction without too great a temperature gradient.

Thus the calculations of the gills involve two distinct problems: (1) the problem of the conductivity as in the case of the cylinder wall; (2) the problem of the surface disposal of heat, that is to say, the passage of heat from the surface of the conducting metal to the surrounding air.

Stated briefly, a definite relation is established between the velocity of the air over the surface, the temperature difference, and the rate of heat loss. In addition to this the power *necessarily* lost in cooling is also established in relation to the other quantities. The results of the investigation may be expressed either in diagrammatical form, or in the following equations:

If θ = temperature difference (degrees F.) between hot surface and atmosphere, and

V = velocity of air; ft./sec.

$\frac{\theta V}{15{,}000}$ = hp. equivalent of heat dissipated per sq. ft. of surface.

and

$\frac{V^3}{100{,}000{,}000}$ = hp. expended per sq. ft. in skin friction, representing the theoretical minimum work done in cooling.

(To be continued)

Results from a Special Spring Suspension Developed for Brewery Trucks and Applicable to Automobiles

Increased Load Capacity Gained by Larger Flexibility and Range of Action—Stability Secured by Coupling Auxiliary Coil Spring for One Wheel with That for Its Mate—A New Factor in the Coupling

Data from an Exceptional Installation Which Has Been Tried with Modifications for Several Years, the Effects Being Noted in Operative Results as Well as in the Upkeep Accounts

By Marius C. Krarup

GREAT reluctance against employing a very flexible spring suspension for heavy, load-carrying commercial motor vehicles is commonly observed among both makers and users and is probably mainly due to four factors: (1) The stability of the load suffers, (2) jolts are aggravated under certain conditions (two potholes in quick succession and similar causes) unless suitable shock absorbers are used, (3) the spring dampers or shock absorbers in the market are not robust enough for heavy loads supported on very flexible springs and (4) a flexible suspension of good quality costs more than a stiff suspension. On the whole, while the waste of power and wear on tires and mechanism due to the toss of the body and load over a set of stiff springs are aggravated for the average running, acute troubles are more liable to occur with flexible springs, unless a reliable system is devised for managing the flexibility automatically in a way that is suitable for all—ALL—road formations and vehicle speeds that must be contemplated as possible. Such management has not so far been found practicable for heavy vehicles, especially not for those made topheavy by their loads and calling for strong forces to oppose rolling and pitching. The majority will rather take their chances with a stiff suspension—one stiff enough to keep all irregular movements of body and load within a small range of action, even if the shocks causing such movements are received on one side of the vehicle only—than with any proposed remedy for the brutal shocks, harmful vibrations and relatively high operating and upkeep cost inseparable from its use. The troublesome steering usually associated with a flexible front suspension also has to do with the preference for small spring action and must be remedied before the benefits of a higher degree of flexibility can become wholly acceptable.

Relief is sometimes sought in flexible tires or spring wheels — whose spring action does not affect the steering perceptibly—but it is too often overlooked that any tire or spring wheel which flexes considerably under the load it carries consumes a large share of the power used for propulsion and that the power so wasted in the useless continuity of flexing incidentally wears out the tire or spring wheel itself, thereby causing additional expense. Only when roads are uniformly rough and the vehicle speeds are high is the account balanced, as between gain and loss from springs of the rotating type—elastic tires and spring wheels—the gains in that case coming from their prompt interception of shocks an instant before the leaf springs are attached, the flexibility which they add to the total suspension and the well-known special advantages of pneumatic tires in absorbing small obstacles without vertical rebound. But even these advantages are not under all road conditions compatible with the stability required for high loads.

Five-ton High Cab "76" with Williams suspension, carrying 6 tons

A Useful Paradox

A high degree of flexibility should therefore preferably be secured through the spring suspension proper for all relatively slow vehicles, and not be derived to any considerable extent from the tire equipment, whose proper function here becomes that of securing friction for traction and of reducing noise and vibration. But such flexibility must be reconciled with stability, which means the avoidance of pitching and rolling, lurching and teetering, the management of load-toss, rebound and oscillations and also the safety of steering. In its briefest form the problem of good "springing" is simply that of COMBINING FLEXIBILITY AND STABILITY. Even the quality of spring material, guaranteeing against sag and variations of tension, may be included under the term of stability, to give full breadth to this useful definition.

Every known method for combining stability with flexibility involves some reduction of the flexibility for severe jolts and much guiding of it into narrow paths of action. The damping of rebound is always included in some degree, if only incidentally, but is not always systematically controlled. Its effectiveness is at all events limited, being greater in proportion as the running-gear is heavy. Pitching is mainly reduced by using flat springs and checking the rebound.

A Brave Departure

While many pleasure cars have had the flexibility of their suspensions very materially increased by means of the Westinghouse air spring equipment and a much larger number of them are fitted with auxiliary coil springs, which provide a short range of flexible spring action especially adapted for coping with the small rugosities of paved city streets, a case in which five-ton trucks have been operated for years with a suspension about twice as flexible as that provided by the manufacturer is so exceptional as to deserve more than passing attention, for the sake of the vital principle it illustrates as much as for the details of the construction employed. Such a suspension is that provided for two Ebling brewery trucks in New York City by Mr. W. R. Williams. Its history and characteristics are given in the following, and it will be noticed that the principal means employed for keeping the truck body and load on an even keel consists in compelling every one-sided jolt to take effect upon the supplementary helical springs on both sides, so that not only is the suspension less flexible for jolts that strike one wheel only than for those striking a pair of wheels squarely, but a certain action is communicated from the side where the jolt is received to the other, tending to extend the leaf spring on this other side, against the gravitation of the axle, but at the same time tending to compress the supplementary helical spring on the same side. This action seems in practice to have a tendency to make the frame on that side follow the vertical movements of the frame on the side where the jolt is received. The complication of factors at work is considerable—too considerable for safe reasoning with different road formations in mind—and the results obtained in practice therefore become so much more interesting.

The Latest Actual Construction

The construction of the Williams spring suspension actually in use on Ebling brewery trucks does not correspond fully to what the designer would consider ideal arrangements, as the installation had to be adapted to the original equipment of the two 1910 Mack trucks to which it is applied and some changes in the shapes and heights of attachment of the front leaf springs might be desirable, but, such as it is, it has given the results referred to later. It is shown in detail in Fig. 1, giving the rear suspension, and Fig. 2 for the front suspension. It will be noticed that in both places the rear end of each leaf spring supports the frame of the vehicle through the intermediation of a large supplementary helical spring, of the railroad truck spring variety; that the movements of the leaf spring, as well as of the coil spring, are guided by means of a 15 in. lever, by bar and shackle connection, and that these levers on opposite sides of the vehicle are made integral with a cross-bar and therefore with each other, the cross-bar forming the pivotal axis for the turning movement of the two parallel levers.

The helical springs at the rear are within the frame lines and extend from the top level of the frame down, while those in front bear against projecting ends of angle irons secured under the frame, their low position being due to considerations of accessibility with regard to the motor and other parts. Though these details in the actual arrangements influence the flexibility for one-sided shocks slightly, they can be compensated in the choice of the spring dimensions and do not greatly affect the practical results, as the cross-bars almost equalize the forces acting upon the two helical springs of a pair, whether they are at the ends of the cross-bar or closer together. Theoretically, if the cross-bar were absolutely rigid against torsion and bending as well as in its bearings, one helical spring of double strength could take the place of the pair of them without changing the effects. The different positions of the helical springs in front and rear are perhaps mainly of interest to show the adaptabilty of the whole plan to different truck designs; the cross-bar, in addition to its main function, giving considerable freedom with regard to the location of the auxiliary coil springs.

The supplementary helical springs add of course greatly to the flexibility of the suspension, as compared with the original leaf spring equipment. With a range of action in one of these coil springs of 6 in., the additional range of action produced at the axle is about 3 in., if the axle is about at the middle of the leaf spring, and the slight angularity of the whole spring movement, especially in front, modifies this relation only a trifle. In the appended table giving the

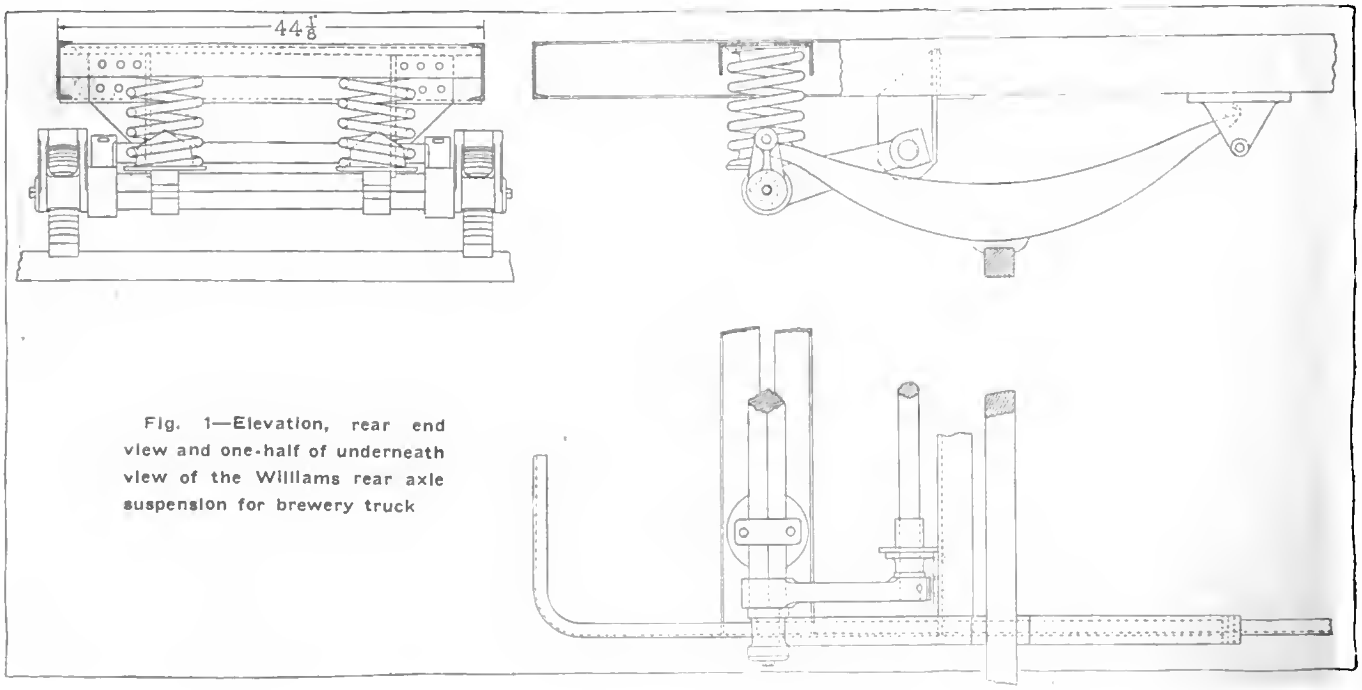

Fig. 1—Elevation, rear end view and one-half of underneath view of the Williams rear axle suspension for brewery truck

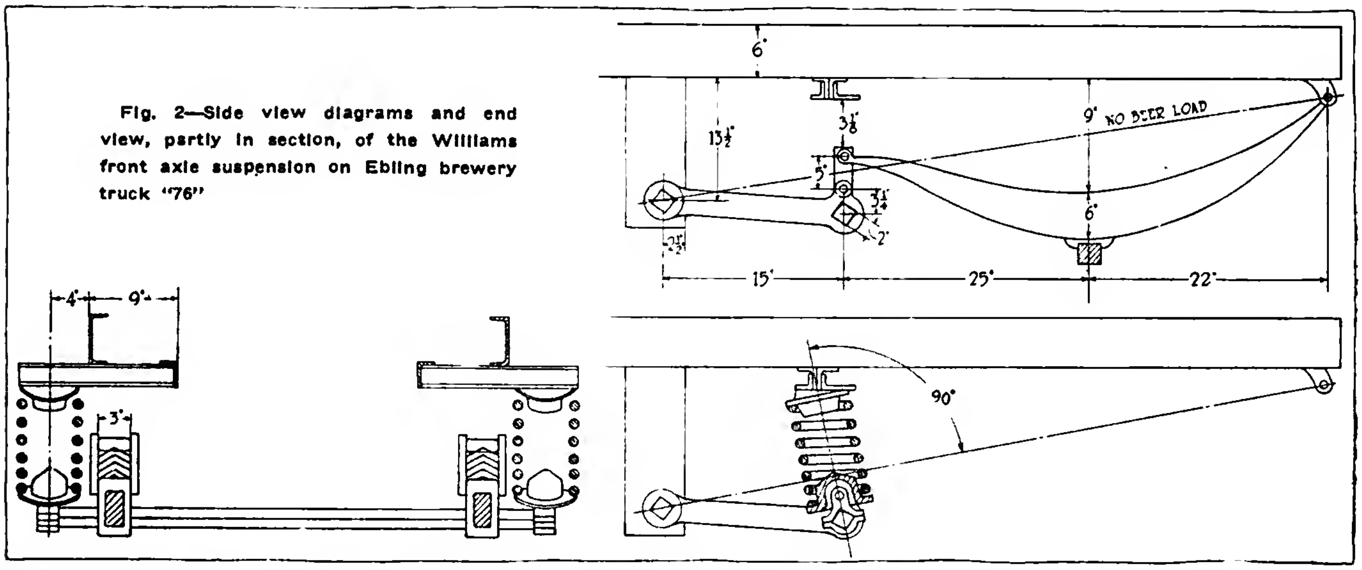

Fig. 2—Side view diagrams and end view, partly in section, of the Williams front axle suspension on Ebling brewery truck "76"

flexibility of the different elements in the suspension, the radical change which is brought about in the relative mobility of the running-gear and the truck body with its load can be followed up in its details. It is so considerable that the question of the means for producing the required stability at once arises. What is there to prevent the body and load from settling down sharply upon the springs on one side of the vehicle, while extending those on the other side, and causing the high load to tip dangerously, and perhaps to oscillate from side to side in a manner that is wholly unacceptable and may set up incalculable forces making for the overloading of the springs on either side and for the breaking of things in general? What, further, is there to prevent the rear end of the load from pulling the rear springs up in the air and pitching forward against the front springs, if the truck is stopped suddenly by the brakes or receives a sudden check from the road, as when it strikes level ground after coming downhill at the rate of speed in which some truck drivers are prone to indulge at times?

If plain leaf springs of a flexibility corresponding to that of the Williams suspension were used, it is known that the results, so far as these undesirable large movements are concerned, would be unacceptable—not to mention what would happen if rolling and pitching were combined, as when a topheavy load coming downhill swings to one side the moment the level is reached and throws the momentum of all the straying forces upon the front wheel and springs at the peak of the turn.

Three Factors for Stability

The provisions which guard against rolling in the Williams suspension comprise three main factors. The cross-bar against which bear the lower ends of each pair of helical springs forms a very rigid rectangle in conjunction with the two guide levers and the other cross-bar, already mentioned, which consolidates these two levers, and, as the four bearings in which the rocking movement of the rectangle take place are also very substantial, this movement cannot depart measurably from verticality in relation to the truck frame, and the greater the tendency is to depart from this desired direction of the movement the greater is the restrictive friction produced in the four bearings of the rectangle. The rolling permitted is therefore no greater than that which could occur with an equipment of stiff leaf springs alone, and, as shall be seen directly, it may be less. The second factor—which is in reality the first and most important one in the origin of the design, working farther back in the chain of causes and effects—does not only resist a tendency to rolling, as the first-mentioned factor does, but obviates such a tendency before it is born. It consists in the action of the united guide levers to compel the helical spring on either side to follow the flexions of its mate, directly actuating it to that effect. By this action every one-sided shock has a less flexible suspension to deal with than a shock of twice as great force which is evenly divided between both wheels of a pair. In other words, the shock which would tend to cause a rolling movement of body and load is more stoutly resisted than one which is squarely received, and, particularly, that part of the spring action which affects the helical springs (as well as the spring reaction, which is frequently more important in affecting the body movements than the first action) is equal on both sides and develops no tendency to roll. The stouter resistance may not be an advantage, but the equalization of movement is.

The square shock on the other hand, receiving the benefit of the full flexibility, develops less tendency to up-and-down tossing of the load at the first impact than would be experienced with a stiffer suspension, while the numerous friction elements introduced in the Williams design must also have a marked damping effect on rebound and oscillations, though apparently not one which has been systematized any more thoroughly than is the case with similar desirable effects produced incidentally, but in lesser degree, in other constructions.

New Effect from Compensating-Bar

The second factor, considered only as the equalizing of the auxiliary spring movements on both sides of the vehicle, is almost identical in effect with that produced under the A. A. Remington patent for Wolseley cars to obviate the roll with cantilever springs—and, according to Mr. Williams, the system in this respect dates back to the buggy age in this country—but the third factor for guarding against roll with the Williams suspension is special and has apparently been incorporated in the design without deliberate intention. The designer does not emphasize it, but it is discernible in the construction. It is hard to trace its exact mode of action under all different conditions of spring and vehicle movements, but it is easy to see that it is present under all of these conditions and to believe that it may be responsible for some of the good results obtained in practice. This factor is the one mentioned at the outset; namely, the arrangement by which the guide levers enter between the two spring elements on each side in such a manner that a compression of both leaf and coil springs on one side causes only the compression of the coil spring on the other side but not that of the leaf spring—on the contrary tending to extend the latter. With the Remington construction the equalizing bar, when turned by a compression of the cantilever spring on one side, transmits a compression movement to the entire spring on the other side, and, as there is no obstruction in the road on that side to cause the wheel and axle to be raised, the tendency is to lower the body on that side, since the distance between body and axle is reduced by the equalizing-action. With the Williams suspension, on the other hand, whenever the acting forces come from the point of ground contact of the wheel they act alike on the leaf and on the coil spring most directly affected, compressing both; likewise, when the forces affecting the springs arise from movements of body and load, they either cause the compression of both leaf and coil spring or the extension of both of them. But, on the opposite side of the vehicle, and whenever there is question of forces transmitted through the equalizing cross-bar and taking effect at the free end of one of the guide levers, then the coil spring directly affected by these transmitted forces is compressed and the leaf spring is extended, or else the coil spring is extended and the leaf spring is compressed. In all cases, however, some modifications in results are due to the facts that the weight of the body and load is superior to that of the running-gear and that the front end of the leaf spring is attached directly to the vehicle frame.

Without attempting to follow the effects of this third factor in all their ramifications, throughout the complicated oscillation and rebound forces which may arise, it is clear that this factor may be a new and useful one in the art of "springing" a vehicle.

Pitching and Steering

With regard to provisions against pitching and excessive rebound it does not seem to the writer that the construction in itself offers all the safeguards that may be needed, but an examination of the illustrations will show that the usual precautions are observed; that is, there is little opportunity given to the body and load for moving forward with relation to the running-gear or for the transformation of such a tendency into a rebound movement of the rear springs coupled with a compression movement of the front springs. And the obviation of roll also tends to reduce pitching, the consolidation of the springs on the two sides rendering it necessary to overcome a greater resistance to the starting of a pitching movement than would be encountered with an ordinary suspension if it happened that one spring in front and one in the rear were already in a position favorable to a pitching movement, as they may easily be with a heavy load, a bad road and a frame possessing that capacity for torsion which now by many is considered preferable to any attempted rigidity of the frame, which after all cannot be absolute.

It should be added that the designer, Mr. Williams, would prefer to use leaf springs with considerable less curvature than is shown in the illustrations, and such almost straight springs would give additional security against pitching.

There remains to be mentioned the steering. After certain changes had been effected in the proportions of the steering linkage of the original trucks, the steering has been found satisfactory despite the greatly increased flexibility of the front springing, and with the use of nearly straight leaf springs the designer estimates that all "kick" can be eliminated. The changes made in the original steering arrangements of the trucks are illustrated in Fig. 3 and described in connection with that of other steps in the development of the whole system.

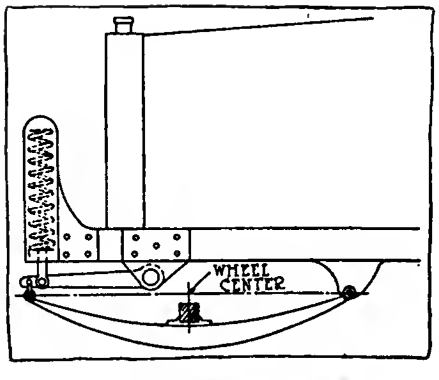

Fig. 4—Williams suspension applied to front of pleasure car

Results in Practice

The results accomplished with the Williams suspension in its progressive stages of development were attested on Jan. 5, 1915, by H. Mehlhop, superintendent of the delivery department of the Ebling Brewing Company, in the following terms:

> "These installations have been very satisfactory.
>
> "The tire mileage is increased about 50 per cent and the trucks will run about one-half longer without overhauling. The suspension is mechanically satisfactory, requiring very little attention or repairs.
>
> "About six months ago we equipped one of the trucks carrying your suspension with a heavier rear axle and springs, and since that time this truck has been carrying 60 to 65 halves. This has been so satisfactory that we intend equipping two more trucks with your suspension this winter, and finally, to equip all our trucks with it."

Though no new units with the improved suspension have as yet been added to the Ebling installation, Mr. Mehlhop recently confirmed in person the estimate of its practical value contained in his letter of fourteen months ago. By "halves" is understood half-barrels of beer, each weighing 200 lb. The load carried on truck "76," which is the one shown in the accompanying halftone illustration, has thus become regularly 6 to 6½ tons instead of 5 tons, and occasionally, it is stated, it carries 6 8/10 tons, which is the limit of its volume capacity in half-barrels. Another 5-ton Mack truck, "75," originally similar in all respects, but not provided with the new suspension, is only allowed to carry a maximum of 5 6/10 tons, in view of the company's accumulated experience with regard to tire wear and repairs of the whole truck mechanism. As in the brewery trade it is reckoned that a rated 6½-ton truck, where it can be used to advantage in the routing of the vehicles, has a 30 per cent higher earning capacity than a 5-ton truck, with only a 10 per cent higher operating cost, the economical importance of improved spring suspension is strikingly illustrated in the present instance, since here, according to the testimony of the truck operators, the improved suspension has brought about the higher loading and earning capacity, while the operating and general upkeep cost is reduced, instead of being increased 10 per cent.

As the Williams system in truck "76" adds rather more than 1000 lb. to the weight of the vehicle, the upkeep economy is so much more surprising. The empty truck originally weighed about 5 tons and carried 5

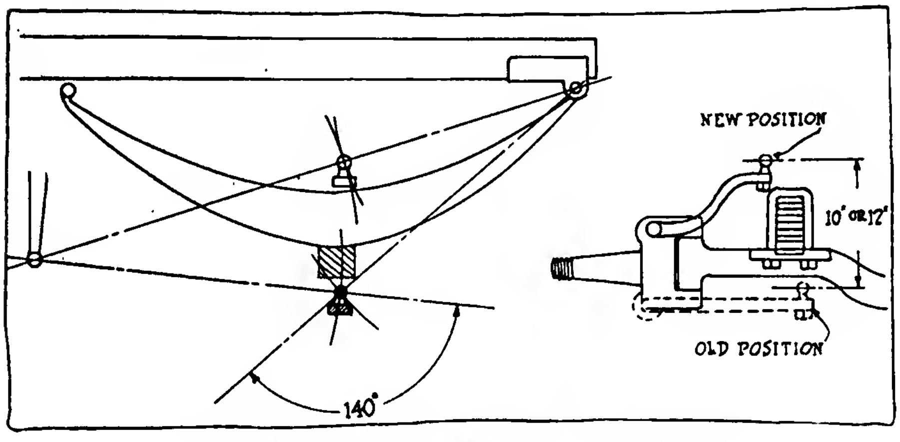

Fig. 3—Illustrating changes made in original steering linkage

tons. With the addition of ½ ton to its weight it carries 1 ton more of useful load. While the added weight cannot be looked upon as an advantage, it may thus be said, as the designer suggests, that the new suspension feature does twice as good work in the matter of carrying loads as the original construction. All the four Mack trucks among which the comparison is established are, however, from 1910 and have all been in brewery service since that year. No. 76 has been operated with the Williams suspension about three years.

Some notes with regard to the earlier stages of the Williams suspension are of interest, showing the growth of the idea and the modifications which have been found desirable. They are here given substantially in the words of Mr. Williams and upon his authority.

Earlier Installations

"The initial truck installation, which was necessarily crude, was applied to a 5-ton Low Cab Mack truck, "79," replacing another special suspension, and remained thereon about three years. This construction, which is not now followed, practically entirely obviated friction for the whole range of helical spring action when the truck stood on a level. The pressure of the little finger would set the front end of the truck in vertical motion, and a stronger finger would do the same at the rear. Four helical springs were used in front.

"After reconstruction, a rear arrangement similar to that on High Cab "76" was installed, but installation of the improved front suspension, with only two helicals, has been deferred, owing to construction difficulties with this type of truck.

"I was forced, however, to correct in "79" certain peculiarities in the steering gear design, which became defects and very noticeable with the mounting of the helicals and the higher flexibility (and which have also been changed in later Mack output)."

The changes made are illustrated in Fig. 3.

"Thereafter the only steering defect in "79" was the difficulty experienced in bad going and in turning wheels when going slowly or at a standstill. This was due entirely to decreased leverage, enforced by the limitations incidental to the change of design. In explanation of the sketch (Fig. 3) I will state that, on looking over a layout of the original front construction of the Low Cab, I find that a 2-in. deflection of the leaf spring produces a horizontal movement of the knuckle-arm ball-end toward the steering-arm ball-end of 1 7/16 in. Evidently, very little action was demanded of the springs. The relation of the three points—steering-arm ball-end, knuckle-arm ball-end and front spring eye—formed an angle of, roughly, 140 deg.

"In the reconstruction the right and left knuckles were exchanged and inverted, and the knuckle-arm ball-end was raised to a point in a straight line with the front spring eye and the steering-arm ball-end. The difference in height of the old and new positions was from 10 to 12 in.

"On the other hand, the somewhat similar action on High Cab "76," to accommodate the entire action of both leaf and helical springs, is about 1/16 in., or less than the play in the gear."

Applications to Pleasure Cars

The very first application which Mr. Williams made of his system for a spring suspension, before it had been developed to its present form, was to a Panhard landaulet to which semi-solid tires had been fitted on the rear wheels, taking the place of 5-in. pneumatics, in the hope of reducing tire expense.

At present he contemplates to apply the improved system to pleasure cars in the form which, so far as the front springing is concerned, is indicated in Fig. 4, while the rear suspension, it is understood, may take either a similar appearance or be patterned more closely after that used for the Ebling trucks.

Conclusions

In reviewing this account it cannot but occur to the reflecting mind that, in order to reach final conclusions, it would be desirable to compare the practical efficacy of the Williams suspension with that of other suspensions in 1915 or 1916 trucks, and to have the comparison of operating and upkeep cost accompanied by such definite data on the tire equipment, repairs and gasoline consumption for each of the compared vehicles as would establish an indubitable equality in the test conditions on the most essential points. Notwithstanding these reservations which may be called academic, as equality of conditions is never maintained for a couple of years in truck practice, or duly recorded, and a margin is always left for surmise on one point or another—it may be said that the Williams suspension makes out an excellent case for High Flexibility plus Stability by Special Means, and presents a realization of such special means which is extremely interesting and worthy of the closest investigation in theory as well as in practice; for pleasure cars, where the construction can be much lighter, as well as for trucks.

Data for Comparison of the Flexibility of the Williams Suspension and the Original Spring Equipment in Two Types of Trucks, the Working Results with Both Suspensions in Both Types Being Known

(All Measurements by Mr. W. R. Williams)

				DEFLECTION UNDER LOAD, IN INCHES, MEASURED AT AXLE						
					LEAF		HELICAL		TOTAL	
	Notes on Equipment	Vehicle Weight	Load Distribution	Load	Front	Rear	Front	Rear	Front	Rear

				Maximum			3	3.44		

NOTE—Leaf spring reserve remains after helical maximum is passed. NOTE:—Actual deflections of the helical springs are about double those measured at axle.

Detroiter Six Has Cable Brakes

Simple Chassis with Continental Engine Latest Detroiter Model

THE new Detroiter Six-45 is the latest model of the Detroiter Motor Car Co., Detroit. Built upon a chassis of 118 in. wheelbase, this six utilizes the slanting frame, the unit attachment of motor and gearbox and the Hotchkiss type of drive through the semi-elliptic rear springs, which are hung under the axle. The motor is a standard Continental block-cast type with the cylinder head detachable.

Cylinders are 3¼ by 4½ in., giving 25.39 hp. by the N. A. C. C. rating, although the power is said to come to 38 on the block at 2000 r.p.m. The displacement is 223.95 cu. in., and the stroke-bore ratio 1.38. The cylinders and upper half of the crankcase are cast in one piece, valves are on the right and, of course, completely housed in, but the carbureter is bolted high on the left center of the casting, so as to make it easy to get at and simplifying the control. Nothing else is placed on the left except the starting motor and the breather and oil gage. On the right are the exhaust manifold, the generator and the water pump.

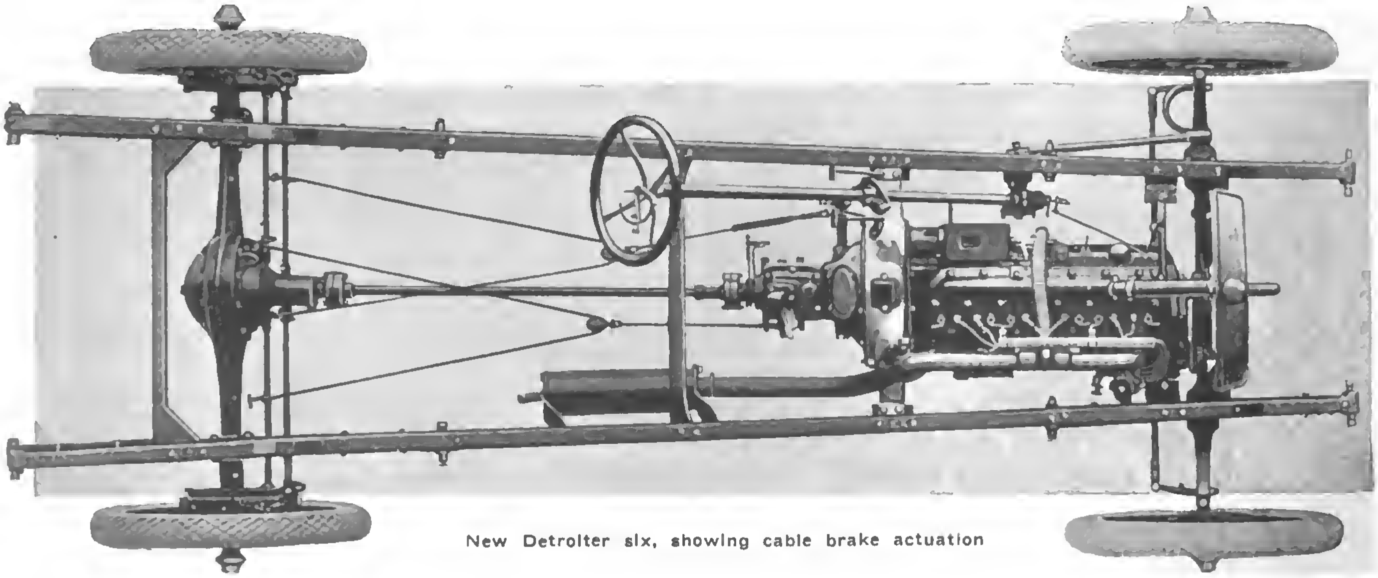
Auto-Lite Equipment Fitted

The Ball carbureter is used, and the fuel is drawn from an 18-gal. tank suspended at the rear of the chassis and delivered by the Stewart vacuum feed apparatus. Connecticut battery ignition is another feature, the distributer being mounted on the right forward side of the engine. Auto-Lite starting and lighting have also been well-applied, the starting unit hugging close to the flywheel housing on the left and connecting to the flywheel teeth by the Bendix scheme for automatically meshing and demeshing. The generator is driven off the end of the centrifugal pump shaft through a coupling that is designed for silence at all times. The electric system is of the single wire type with grounded return circuit.

From the figure mentioned above, it will be noted that this engine is of the moderately high-speed type, and throughout the internal construction this idea has been carried out by balancing the rotating and reciprocating parts and making them as light as possible for the work they have to do. The crankshaft is a three-bearing type that has 2⅛ in. main bearings and 2¼ in. crank-pins. The rods are long and drop-forged from 0.35 carbon steel and they attach to light iron pistons that are fitted with two rings each. In the valve system, the passages have been made of a generous size to prevent any restriction of gas flow, as is evidenced by the valves having a clear opening of 1⅝ in. They are made with nickel-steel heads welded to stems of carbon steel. Timing gears are helically cut, and the timing gear is made of specially prepared silk to insure quiet operation—a refinement that has been very quietly developed by motor engineers and which does much for the cause of silent motor operation.

Clutch and gearset assembly are compactly arranged to bolt to the flywheel housing by a regular form of bell construction, and they are designed in conformity with good and conservative practice. Five driving steel plates and six driven plates that are faced with Raybestos make up the clutch assembly, which requires no lubrication save at the bearings. The gears have a ¾-in. face, and are made of crucible nickel steel, case-hardened, heat-treated and ground.

It is doubtful if greater simplicity could be worked out in the construction of the chassis back of the power unit than has been found possible in this Detroiter. This is especially due to the elimination of either a torsion tube or torque rod by the use of the Hotchkiss drive. Thus simply a plain drive shaft, fitted with a universal at either end, spans the distance from gearbox to rear axle. Even the conventional brake equalizers are absent, a unique adaptation of pulleys and steel cables taking their place. The top view of the chassis will show this feature clearly. Running part way back from the foot brake and hand lever are two rods that terminate at pulleys through which the steel cable passes. The ends of the cable attach to the levers on the brake-operating rods that are attached to the axle housing. Pressure on the brake control, therefore, is transferred through the rod to the pulley, and thence delivered equally through the cable to the service or emergency pair of brakes, as the case may be. This is about as simple as a braking system could be made, and yet it is strong and positive in its action and should be noiseless. Needless to say, there is an adjustment in both sets of



New Detroiter six, showing cable brake actuation brake connections to take up any slack in the cables. The brake drums are 12 in. in diameter and have a 2⅝-in. face.

Springs Are Extra Long

A pressed-steel housing, ribbed at top and bottom externally, is used in the construction of the floating rear axle. The axle gears are of the spirally-cut variety now so universally used, and the whole differential unit operates on ball bearings, with roller bearings in the wheels. The rear cover is made as large as possible, so that it is easy to get at the gears for adjustment or other purposes. In order to be amply strong, especially in the case of the rear set which has to take the drive and torque, the springs are made of chrome-vanadium steel. Riding qualities are fostered by making them long and flat, the rear pair measuring 52½ in. and the front 36 in. The rear pair are substantially hinged to frame brackets at the front end, and are shackled at the rear to the bent-down back ends of the side members of the frame. Although underslung from the rear axle, the car nevertheless has a road clearance of 10 in.

Detroiter Six-45

At the present time, only the five-passenger touring body is offered, and it carries complete appointments and equipment in every respect. The upholstery is leather, and the tires are 33 by 4 in. all around, the rear set being of the non-skid variety. Special fittings, such as a tonneau windshield, Motometer or wire wheels, can also be furnished, though at extra cost.

Exhaust Turbine Drives Generator

WHAT may prove to be a valuable development and a new use for the wasted exhaust pressure, is the turbine operated generator. The turbine is driven from the exhaust gas. The idea was suggested to two employees of the Old Dominion Copper Co., Phoenix, Ariz., Charles W. Shepard and Harry W. Payne. The copper smelter is illuminated by a generator driven by a turbine which secures its power from exhaust steam.

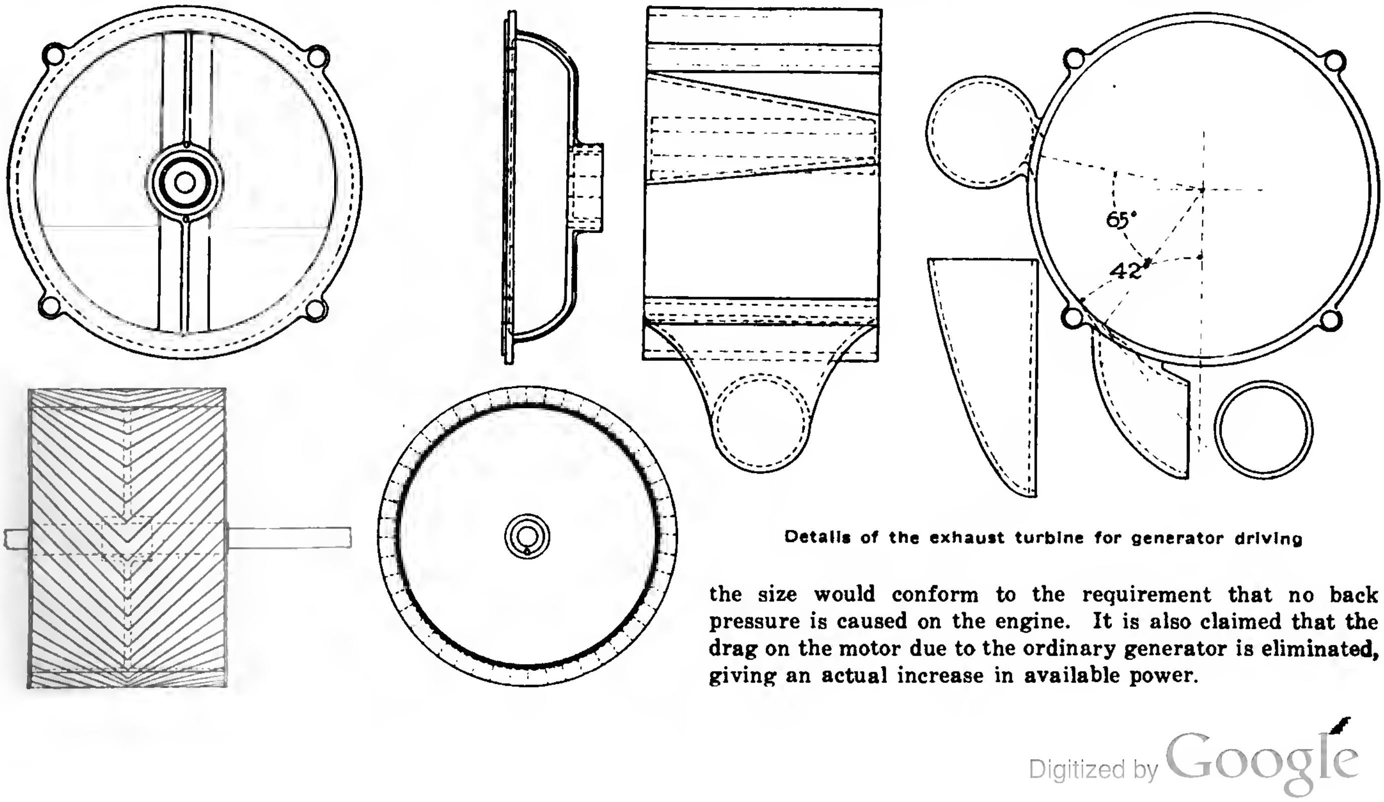
In converting this idea to one which will be practical in automobile usage, it is the plan of the inventors, who have taken out a patent covering the idea, to do away with the muffler. The turbine in its present form weighs eight pounds, being made from aluminum, and is comparatively inexpensive.

The inventors state that the turbine has not as yet been perfected, but that they are actively engaged on the device. The patent was taken out after it was seen that such a machine may develop into a practical attachment. The illustrations herewith show the device in its latest form. It will be noted that the turbine wheel bearings are on a projection from the head of the casing, thereby avoiding the bad effects of direct heat.

The turbine wheel has the vanes set at a 90 degree angle, the object being that the exhaust from the engine enters the casing on a line parallel to the shaft and at all times five blades are receiving the force of the flow, retaining it for 65 degrees or over one-sixth revolution.

The drawings shown were prepared to make the installation on a Ford car, and the device is to be placed on the left side of the engine, under the hood. From the experiments noted, it would seem that the generator would be geared about 1 to 3 to the turbine. In experiments made so far the inventors claim to have driven the turbine at 1200 r.p.m. while the engine was idling and with plain bearings on the turbine. It is planned to use a centrifugal governor on a cut-out if too much speed is developed, although this and other details are to be the subject of further experiment.

On the present device the nozzle through which the gas enters the casing is ⅛ in. wide, this size being used so that the size would conform to the requirement that no back pressure is caused on the engine. It is also claimed that the drag on the motor due to the ordinary generator is eliminated, giving an actual increase in available power.



Details of the exhaust turbine for generator driving

Good Cooling Features New Rotary Valve

Kline Patent Discloses Some New Ideas in Rotary Valve Construction

OF the great multitude of rotary valve motor patents, that just granted to H. J. Kline appears to be one of the most promising that has been seen for some time. In designing a rotary valve the problem to be mastered is to keep the valve gas-tight and properly lubricated, to compensate for wear and to prevent dirt and foreign matter that would score the valve and its bearings from coming in contact with these parts. It is also necessary to keep the valve at as low a temperature as possible, at the same time holding the temperature constant for all loads and speeds, if such is possible. By this application the fit of the valve will not vary as much, nor will the lubricating oil carbonize and become gummy. It is also possible by this application to so construct the valve and its related parts that a minimum pressure will be exerted on the valve due to the force of the explosion. In short, the problem is to use what is commonly known as a balanced valve. This can be accomplished in part by limiting the exposed valve area to as small a surface as practical conditions will permit.

The Kline valve was designed to meet these requirements as far as possible. By using an automatic auxiliary exhaust valve, in conjunction with the main or rotary valve, the former, controlled by the piston, may be so designed that it will carry away a large part of the heat of the exhaust. At light loads, when the throttle is slightly open, the exhaust pressures within the cylinder are such that the automatic valve is supposed barely to lift. At full loads, where the exhaust pressure is very high, the valve should be forced wide open, so that the larger part of the exhaust gases and consequently the major portion of the heat, would be carried out at the lower end of the cylinder. Thus the heat carried past the main or rotary valve would be more or less uniform and the temperature be practically constant for all loads. If this is so, the expansion of the valve should vary its size but little.

It is also a necessary deduction from these facts, that temperature will be lower. This condition is conducive to proper maintenance and life of the moving parts.

There are several factors that assist in maintaining a low-operating temperature of the valve and its bearings, aside from the auxiliary exhaust. One is the proximity of the intake manifold, which will absorb a great deal of heat. A second is the fact that the valve is hollow and may be either water- or air-cooled, and the third is the full water circulation around the valve casing.

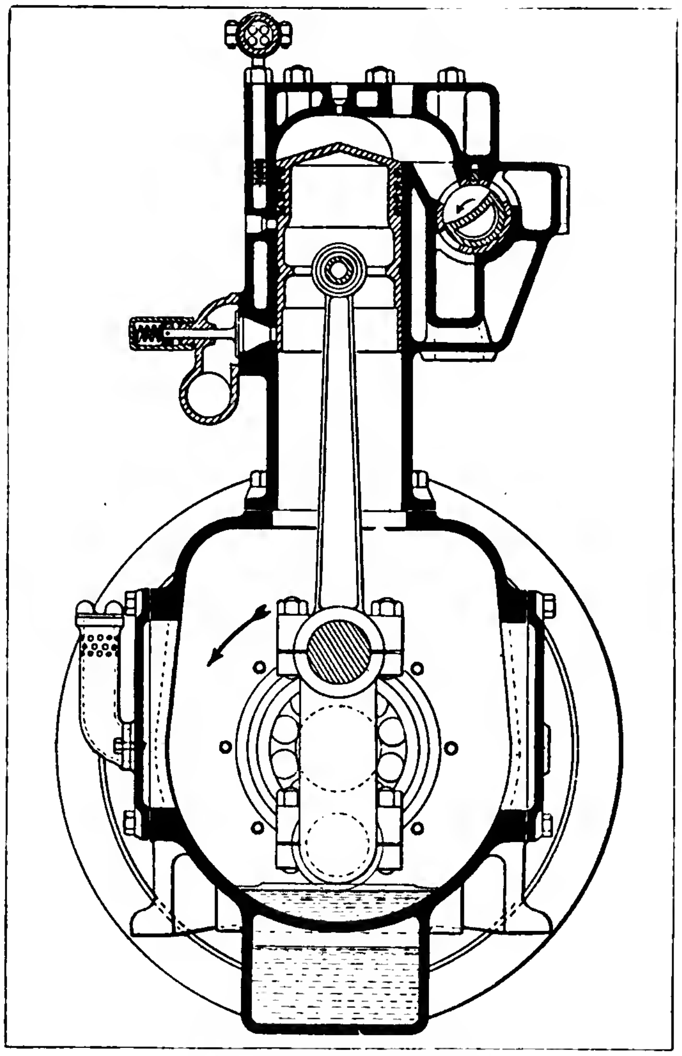


Diagram of Kline rotary valve engine

In order to secure a proper fit of the valve and to maintain a gas-tight joint after some wear has occurred, a further problem arises. The location of the exhaust and inlet manifolds in respect to the valve is one of the factors in keeping the valve tight. The Kline valve rotates *toward* the cylinder, so that when pressure is applied, by way of the ports leading to the combustion chambers, the valve will be forced against the opposite side of its casing.

The inventor claims that, as the valve rotates under this pressure, it tends to pivot or roll toward the cylinder, and keeps this side sufficiently tight to form a gas-tight joint.

Packing Only a Safeguard

When the valve is new, it should be so tight that packing would be unnecessary, providing, of course, that the fit is quite close and the valve temperature will not vary to any great extent above or below the normal operating condition. To compensate for the wear of the valve, there are packing rings and a packing strip. This strip bears on the rings, so that when new, it will not touch the valve at all, simply conforming to the bore of the casing.

The packing rings do not revolve with the valve, but creep slowly around, due to the cylinder pressure forcing them against the side of the grooves in the valve. This creeping action, it is claimed, will slowly wear the ends of the packing strip so that it will gradually settle as the valve wears and will still continue to keep this point sufficiently tight.

Lubrication of the valve is accomplished by forcing oil to the bearing surfaces between the cylinders, inclosed by the packing rings. The oil film thus created is expected to carry the valve so that the portion opposite each cylinder will bear but very little load. Theoretically, these portions are free of the bore.

The oil is fed from a duct above the valve, and after flowing around the bearings, is gradually drained out at the bottom by another duct below the valve, which carries it back to the original source of supply.

Kerosene Engine of Simple Design

Duplex Exhaust and Intake Manifold Employed for Fuel Vaporization

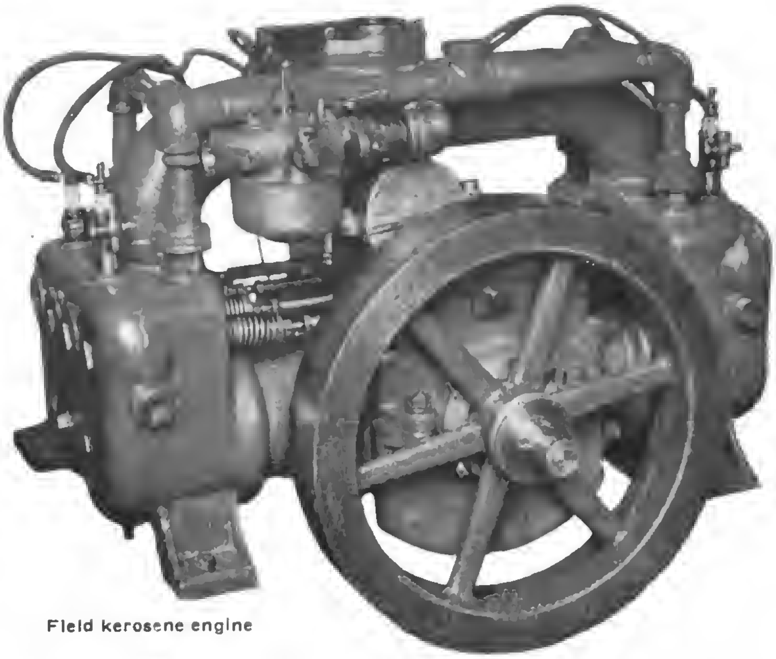
THE Field Motor Co. of Grand Rapids, Mich., has begun the manufacture of an engine different from any other type on the market. It is a horizontal motor, directly opposed, and it is said to run on gasoline, kerosene and distillates. It has but two cranks and two connecting-rods for four pistons which gives such a compactness of construction that it occupies a space only of 11 by 23 by 14 in.

The pistons and the tie rods are made from one piece of steel, the tie rods being flush on the crankshaft, although permitting plenty of space for operation. This gives practically a continuous piston from side to side. The tie rods which connect the pistons have sliding fits on each side of the crank webs and also on the top and bottom of each crankshaft bearing.

Uses Any Carbureter

Any standard carbureter may be used with the Field motor. The secret of its success in burning low-grade fuel is the fact that all charges are preheated. The carbureter, unlike all other engines, is above the cylinders and the charges gravitate down to the manifold. One manifold supplies all cylinders and it is so arranged that the exhaust heat affects the charges from the carbureter preparing them for a perfect explosion in the cylinders. The arrangement of surfaces and valves controlling the exhaust has not been patented.

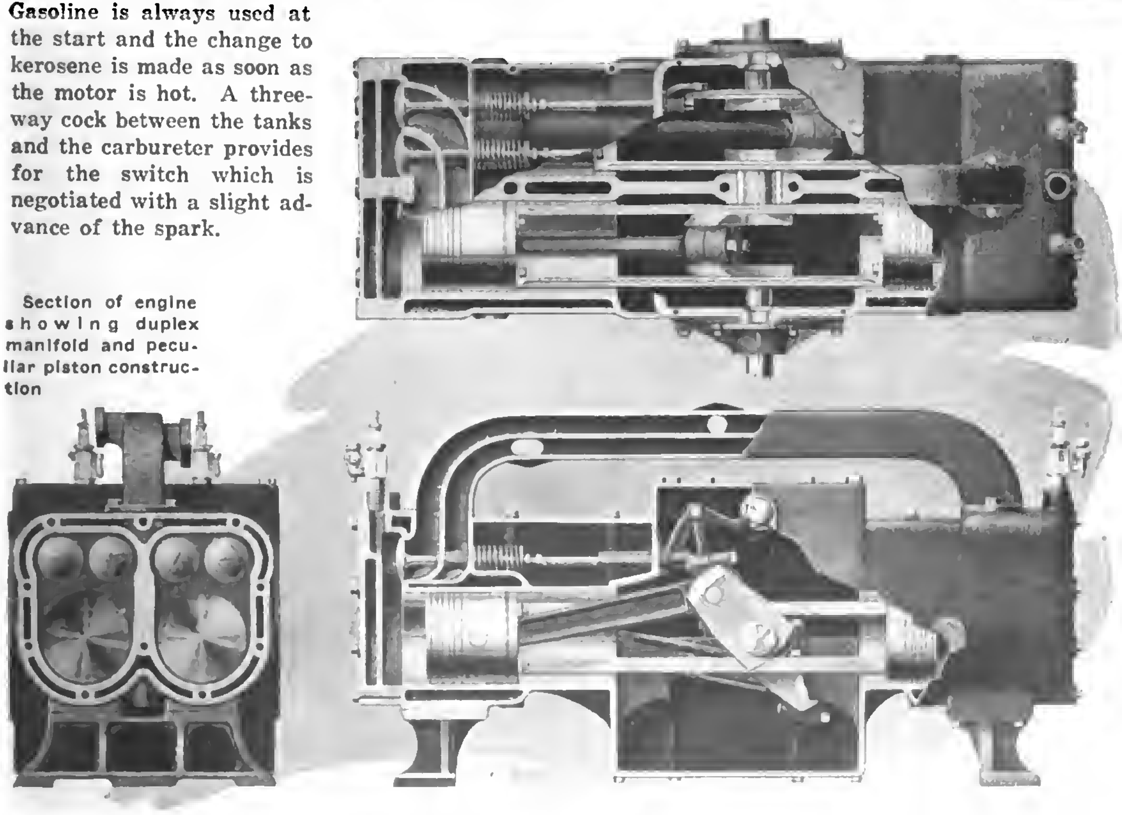
It is claimed that no adjustment of the carbureter is necessary in switching from gasoline to kerosene. Gasoline is always used at the start and the change to kerosene is made as soon as the motor is hot. A three-way cock between the tanks and the carbureter provides for the switch which is negotiated with a slight advance of the spark.



Field kerosene engine

Because of the compact style of construction the motor consumes but very little space and is claimed to be adaptable to airship use. Its simple construction also makes it adaptable to tractors and motorboats. But three operations are necessary to expose the interior of the engine, and it can be held in position with four bolts to the frame. The accessibility is one of the cardinal features. The motor is block-cast with removable heads, the cylinders being bored in line, with one boring bar. The ends are milled and squared at the same operation. All parts are inclosed. With the pistons carrying the connecting-rods lubrication of the wristpins is excellent.

A set of inclosed spiral gears operate the camshaft and magneto. An adaptable governor, attached by a simple operation, will permit the engine to be used for stationary purposes.



Section of engine showing duplex manifold and peculiar piston construction

The Sizes of Motors for Trucks and Outline of British Practice in This Field

By W. D. Williamson

Part 2—Outline of British Truck Motor Design

(Continued from page 477, issue of March 9)

CRANKSHAFT BEARINGS—In several engines of the three-bearing type the middle bearing is the same size as the big ends, and this may offer manufacturing advantages and seems to be satisfactory in service. In the way of standardization and reduction of spare parts, some makers also have the front bearing of the same dimensions. The average lengths, however, for the three bearings, taking the length of the connecting-rod big end bearing as 1, are 1.21 for the front, 1.17 for the middle, and 1.48 for the rear.

Setting down average surfaces as found from the engines examined, where $D =$ cylinder diameter, we have:

Big end:—Average pressure, 765 lb.
Big end area = piston area, 2.73
Diameter of crank pin $= 0.4\,D + \frac{1}{4}$ in.
Gudgeon pin:—Average pressure, 2100 lb.;
Gudgeon pin area $= D^2$: 9.6
Diameter of piston pin = big-end diameter — 1 1/32 in.

Main bearings have the same diameters as the crank pin, and the lengths are respectively 1.21, 1.17 and 1.48 times the crank pin length.

These dimensions are put forward, not as being the ideal, but as representing current practice as shown by the engines of which the requisite data were available.

Only two prominent builders of commercial vehicle engines use ball journal bearings for the crankshaft, as in Fig. 7.

Valves and Valve Setting

With the exception of the Daimler vehicles, all British commercial vehicles have engines of the poppet valve type. These valves are usually of 3 per cent or 3.5 per cent nickel steel with seats at 45 degrees. The London General Omnibus Company, after experimenting with other materials, standardized mild steel valves suitably case-hardened and ground to overcome the difficulty of wear in the stems. Where trouble has arisen due to excessive wear or pitting of the face, nickel chrome steel has been used with advantage, while one maker has found a remedy in a return to cast-iron heads.

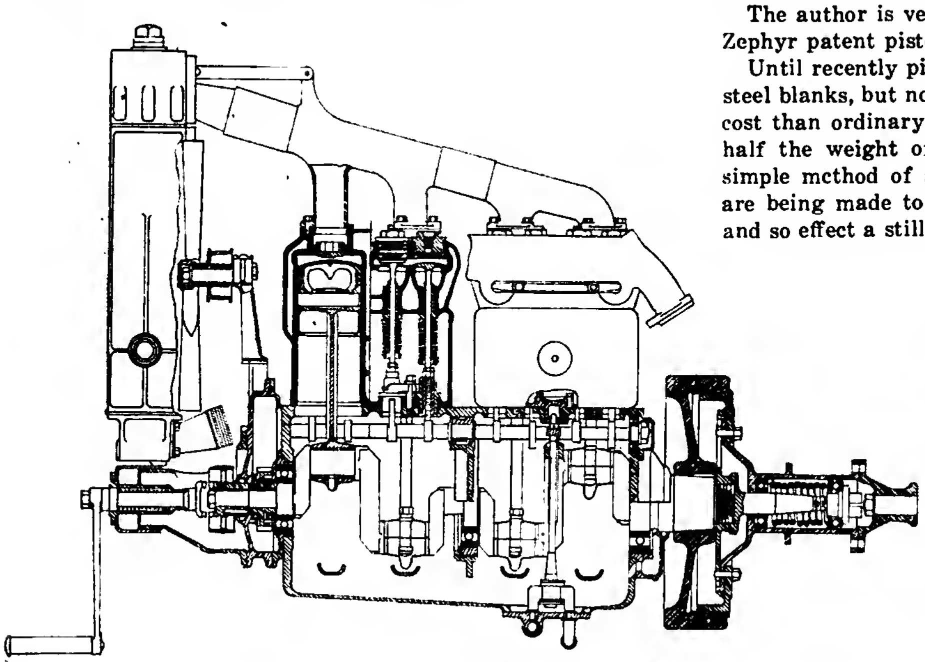


Fig. 7—Commer Car with ball-bearing crankshaft

Examination of a number of engines showed an average of:

Opening in valve seat = 0.46 cylinder diameter.
Valve lift = cylinder diameter: 12
Effective area of valve opening = cylinder area: 10

Valve tappets adjustable by set screws at the upper end and fitted with rollers at the lower end are standard. Figs. 8, 9 and 10 show care to insure ample wearing surface in the tappet guides with tappets as light as possible.

The average taken over a number of valve settings is shown as a diagram in Fig. 11.

Pistons

Except in one or two cases, no great effort has been made for obtaining very light pistons. General practice favors three rings above the gudgeon pin. The Dorman engine is a notable exception, being fitted with a special type of compound ring which gives excellent results. The usual method of securing the gudgeon pin is by one set screw, which must be securely locked. Where two set screws are used for this purpose, it is found difficult, even by the use of jigs, to insure that the holes in the gudgeon pin and bosses are drilled exactly the same distance apart, and the smallest error may cause piston distortion. Two or three makers use a ring for retaining the gudgeon pin, and also use a fifth ring acting as a scraper.

The author is very strongly impressed by the claims of the Zephyr patent piston shown in Fig. 12.

Until recently pistons of this design were turned from solid steel blanks, but now they are made in cast iron at no greater cost than ordinary pistons. Pistons of this design are about half the weight of the ordinary type and allow of a very simple method of securing the gudgeon pin. Arrangements are being made to produce these pistons in aluminium alloy and so effect a still greater saving in weight.

Lubrication

Some form of pump for oil circulation is practically always fitted. The type most in favor is the gear pump, which answers the purpose extremely well for oil, although not so successful when, as in the past, it is used for circulating jacket water. Oil is usually fed under pressure to the main bearings and through the crankshaft to the connecting-rod bearings. Cylinder walls and gudgeon pins are lubricated by splash. Excess oil is directed to the timing gears in the Dorman.

The ideal would appear to be some combination of a forced system with the trough system as used in Daimler engines, the two systems being independent, so that in case the forced system fails the bearings are not endangered. There should be no ill results due to the increased supply of oil, so long as efficient means are provided to prevent over-lubrication of the piston.

The Wolseley has a notable arrangement of oil collecting galleries, and the Albion (Fig. 8) has thrower rings arranged on the crank webs for the lubrication of the big ends.

More consideration might be given in many cases to the position of the crank chamber filling orifice. It should allow of a large tin being up-ended over it without fouling other parts and without wasting oil. It should be provided with a filter.

In Wolseley and Leyland engines these points have received attention. In the Dorman the oil is introduced through the top of the fan bracket. (See Fig. 18).

Drive for Timing Gears

With a few exceptions, notably the London General Omnibus "B" type (Fig. 13) and the White and Poppe (Fig. 10) fitted to Dennis lorries, poppet valves are arranged on one side. The chief disadvantage would appear to be that it necessitates somewhat small valves or gives greater overall length to the engines.

For the camshaft drive the usual practice is to have two helical gears of steel, the pinion being hardened and the wheel, to insure quiet running, being of a steel giving the requisite wearing properties without hardening.

In the larger motors these gears usually have teeth of 8 in. diametral pitch and 1¼ in. wide.

Silent chains are used in the Daimler (Fig. 14), Wolseley, and Tilling Stevens.

Belsize engines have ⅝ in. pitch roller chain drive, which appears to be quite satisfactory as regards both silence and life.

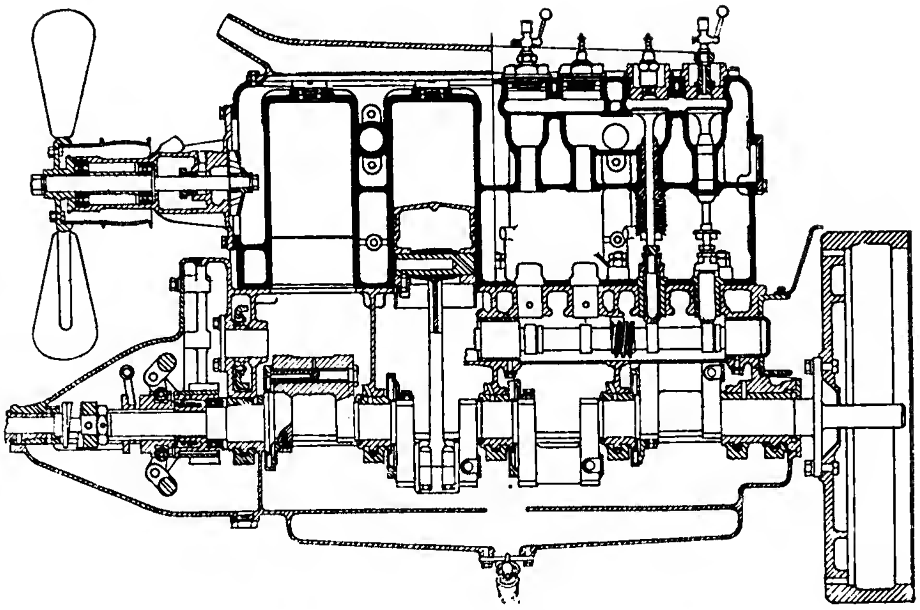

Fig. 8—Albion truck motor, lubrication notable

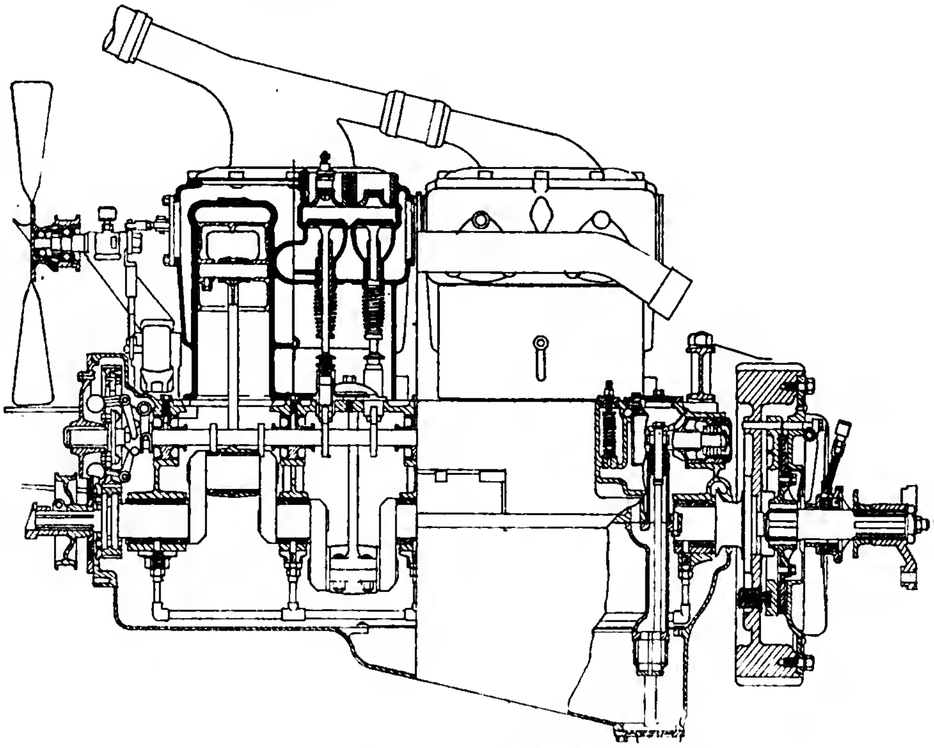

Fig. 9—Napier motor, a representative design

Drives for Pump and Magneto

Pumps should be easily accessible for repacking of the glands, and the contact breaker should be in such a position that it is not only accessible to the hands, but also so placed that the mechanism can be seen when the cover is removed.

These conditions are obtainable most readily by the fitting of a cross-shaft over the timing case.

In in the Pagefield arrangement (Fig. 15) this cross-shaft is set at an angle so that the pump is thrown down in line with the outlet from the radiator, and the contact breaker is lifted up to become quite the most accessible part when the bonnet is lifted. In this arrangement the angle of the helical gears is modified to allow of the spiral gear on the cross-shaft engaging with the wheel on the camshaft.

The Halley, Leyland, Tilling Stevens, Tylor and White and Poppe are other engines where the cross-shaft is adopted, and only one gland is required for the pump. The White and Poppe arrangement is shown in Fig. 16. The Napier (Fig. 9) and the Dorman are typical examples of the arrangement where pump and magneto are placed in line alongside the engine.

The Albion arrangement of pump drive (Fig. 8), where the cylinder jacket serves as the pump casing, is an entire departure from common practice, and possesses distinct advantages in the way of simplicity.

Governors

Whether or not a governor should be fitted has not been settled satisfactorily. In ordinary commercial service a governor should provide a means of insuring that the vehicle is not over-driven when light. On the other hand, a vehicle with a governed engine is not as nice to drive, the power of accelerating beyond normal speed in an emergency is absent, and gear changing is, perhaps, not quite so easy. The type of governor most popular with the ordinary driver seems to be the one that is most easily put out of action.

It is difficult to arrange for the governor to combine accessibility with simplicity, but the Daimler (Fig. 14) and the Pagefield are worthy of note in this respect. The latter is entirely inclosed.

The practice followed in some cases of arranging the governor to act on the carbureter throttle valve is not calculated to give the best results in fuel consumption. In the case of a carbureter with a throttle valve shaped to give a rich mixture at very small openings, for easy starting, the throttle may assume this position on a favorable gradient at high engine revolutions, and the mixture taken into the cylinders may consequently be much too rich.

Half Compression and Starting Devices

The author is of the opinion that for the larger engines a simple arrangement for releasing compression for starting purposes is a decided advantage for lorries that are parked in the open or for vehicles, such as furniture removers' vans, that may have to stand for some hours in the coldest weather. If it becomes necessary to have female drivers for the heaviest vehicles, anything that helps to ease matters for them will find favor, and it may be that the self-starter proper will find advocates. For the present, the fitting of self-starters to commercial vehicles has not been attended with success. They have been tried with the idea of saving fuel by encouraging the driver to stop his engine at every halt, but the saving effected has not been all that was expected.

DORT CAR NEAR IDEAL DIMENSIONS — STEERING WHEEL POSITION HIGHLY IMPORTANT — AN AMATEUR'S IDEAS OF COMFORT AND HOW THEY WORKED OUT

Dort Dimensions Close to Ideal

By E. Planche

(Chief Engineer Dort Motor Car Co.)

REGARDING the article by Mr. J. E. Schipper on the subject of body proportions to give comfort to the driver of ordinary height.

We have made a drawing of the body following the same lines of a sketch published in your estimable paper and besides the figures you recommend, we have put the figures that we have in our Dort car and in the third column the dimensions that we think would be the ideal from our own point of view.

You will please notice that for a small car the Dort comes very close to the measurements you recommend, and we must say that from our own experience in this car, when driving under all kinds of conditions of weather or road, we have found the sitting conditions for the driver very pleasing and not such as to place any undue strain on his nerves.

Thinks Steering Wheel Position Most Vital

By A. A. Bateman

(Jackson Automobile Co.)

I WISH to compliment Mr. Schipper on the able manner in which he has handled a very important subject. However, there are some points which I think are slightly overdrawn. For instance: the heading of the article "Driver's Lot 99 Per Cent Discomfort." This, no doubt, is to attract attention to the article. It certainly is not intended as data from such a reliable source. I believe that the comfort and convenience of the driver has not been entirely neglected by the majority of designers. By careful survey of the hundreds of accessories that are made and applied to the automobile of to-day a very large per cent are designed with one purpose, namely, for the convenience and comfort of the driver.

Owners' Views Differ

Regarding the height of seat, steering gear, etc., also distance from the back of the seat to the steering gear, there are a great many things that have to be taken into consideration before a definite dimension can be used to satisfy even the average driver. The height of the seat, for instance.

I note that the dimensions on the car mentioned run from eleven to sixteen inches. Will venture to say that the manufacturers have been asked by purchasers to make their seat just a little higher than the highest and likewise some will want the seat lower than the lowest. This also applies to the height of the wheel at the distance from the back of the seat to the wheel.

I have noticed in a great many instances, and I think many who have made a like observation will agree with me that a car which has just the proper location of the wheel for any particular driver who, when sitting in his natural position, either erect or slightly reclining, will be in such a position that a line drawn at right angles of the column through the rim would intersect with the hip pockets of the driver and at a height when the driver's hand is on the center of the wheel the forearm will be on the same line. This, of course, would necessitate a greater or less distance from the back of the seat to the wheel, depending upon the size and build of the

· Note—Drivers not quite erect.
K—Must one lean to shift gears.
L—Must one lean to apply emergency.

driver. I think the greatest cause of fatigue after a long drive is due more to the unnatural position of the steering wheel than the shape of the seat or hack.

As to position of the shifting levers, care must be taken not to get them too close as to interfere with the driver getting out of the right side of the car, as at least 50 per cent of the entrances are made from the curh.

Also the brake levers should he so placed in such a position that they will not he much hack of an upright position, as thereon the angle becomes so great that very little power can be applied.

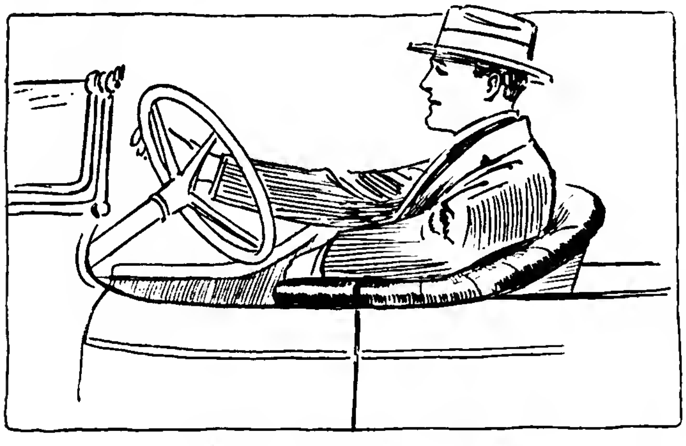
The possibility of establishing a limit for the location of a steering wheel is practical, but as to the location of the doors, shape of the back of the seat and the amount of room in the tonneau enters into each individual design. I believe the solving of this problem will eventually be adjustable driver's seat, both as to height and fore and aft. Also the steering gear and pedals so constructed that they may he easily changed to suit any particular driver.

How to Make a Stock Car Comfortable

By C. A. Du Bois

BEING an owner-driver, I have taken great interest in Mr. Schipper's article on Driver's Discomfort, in your issue of Feb. 3, and agree with him in his remarks. Would say in addition to his comments that I think that the proper height of the cushion should he from 13 to 15 in. from the floor for the average driver, or so that his feet should rest squarely on floor board. This height and position of feet gives him a chance to raise his body when taking bad spots in the road and relieves the strain on his back. It also makes it easier to leave seat, as you are not ohliged to grab hold of steering wheel with one hand and pull yourself up at the same time giving yourself a push with the other hand on back of seat. In entering you do not have to drop into seat. If this were not true why did not the wagons and carriages of the past have their seats as low as 6 or 8 in. as they had the advantage of easier springs. I find that the driver in most cases when he has a guest sitting by his side is obliged to leave car on driver's side, as very seldom do you see guest leave car before the driver; as levers are in the way it is doubly hard to leave car and climh over guest, therefore, it does not make much difference whether levers are bent or offset.

Last year I had a demonstration of three cars of the $1,100 to $1,300 class with the intention of huying, and after driving all three purchased the one that was most comfortable in regard to height of cushion from floor, although the other two cars had hetter engines. On both of the rejected cars I could not drive over rough roads without hitting the steering wheel.



C. A. Du Bois' padded door edge

Changes That Made Comfort

While the car I purchased was not all that I desired in comfort, I immediately started in to make it so. I placed on the front doors of the car 8 by 2-in. cushions to correspond with the upholstery of the arms or side of the car in the rear. My idea in doing this was because the end of the upholstery came where I naturally would rest my left elbow. As far as appearances go it is not noticed except when door is left open. Next I placed a sliding steering wheel on the car, which gave me 16 in. between the steering post and the edge of door frame to enter car. When wheel is open it gives me an opportunity to enter the car in a standing position and adjust my clothes before sitting.

When changing gears I had to lean forward about 12 in. to go into second speed, and when I did I usually hit my knuckles on the bottom of the dash cowl. To eliminate this I made a 3½-in. offset extension of 4-in. on the gear lever that gives me now an opportunity to make changes with very little motion and very much easier as on account of the extra leverage I can change by using thumb and finger only. I placed extensions on foot pedals of 3 in. and made a foot throttle that fastened on side of gear lever box that has a side motion rather than the up and down or hutton kind. Was unable to reach with comfort the throttle that was fitted to the car originally.

This side motion throttle has the added advantage of smoother action when riding over bad spots and quicker acceleration and gear changing as the throttle is at side of you, when in natural position, on floor of car.

Am now making a driver's cushion that slides on a frame so that when in right position can be clamped in place. The cushion at driver's back is to be separate and fastened at bottom on hinges that are adjustahle forward 3 in. and up or down 3 in., the space at top being inclosed in the bellows type of upholstery, so that it would not interfere with lines and appearances of car.

A Lazy Man's Ideal

By making these changes you see I have the ideal lazy man's car and at the end of a day's run am not fatigued as I would be if I were using a car in the condition that it was when purchased. I think that the future ideal car will have two doors only, one wide door at driver's side and an ordinary door on opposite side in rear, giving the tonneau passengers an opportunity to enter at curh. The front seats to be divided with 10-in. passageway and driver's seat and back to be adjustable. With this arrangement you have less door rattle and it is possihle for driver to enter at curb.

McIntyre Axle Resists Side Shocks

With reference to the description of my front axle in THE AUTOMOBILE for Jan. 27, you have not given this device full credit, as I notice that you have made the statement that no road shocks barring a glancing blow will deflect the steering. You have cut out the hest portion as this device is especially designed to take care of the glancing blow from the unevenness of the road, such as getting out of car tracks and ruts in the road.

For your information will say that one of the tests made with this axle is that you can drive the car, say, at an angle of 45 deg. so that when the front wheel is about to strike the curbstone or a similar obstruction, you can let go of the steering wheel and the car will mount over it. The same applies to striking an unexpected ohstruction on the road; the steering wheel will not be jerked out of the driver's hand as there are no shocks transmitted to the steering wheel in either case. ELMER E. MCINTYRE.

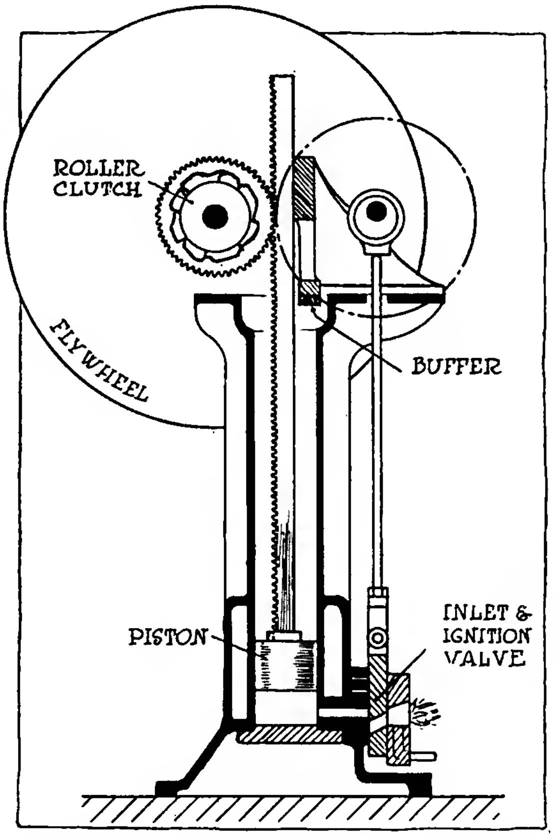
The History of the American Automobile Industry—21

Langen and Otto's Experiments with an Engine Having a Free Piston—Working Stroke Atmospheric and Power of Explosion Only Partly Utilized—Noise and Vibration Were Troubles

By David Beecroft

WITH the last two instalments of this history the work of Stuart Perry in America and Lenoir in France was reviewed. Both these inventors took the steam engine as their model, to a considerable extent, and tried so to alter it that it would operate with a different working medium. Coming to more recent years we see a notable change, in that the steam engine type was largely abandoned and totally new constructions made the subject of endeavor.

Within the next half-dozen years, after Lenoir's first patent, a half-dozen gas engine inventors appeared. Siemens and Hugon patented engines using platinum ignition the same year, 1860. W. E. Newton in a British patent of 1861 describes an engine employing pressure, or compression, which he secured by a second cylinder and piston, much like a modern two-cycle, and using jump spark. F. H. Wenham in 1864 patented a free-piston engine, Hugon in 1865 an improved form with flame ignition, and following these Otto and Langen brought out their patent in 1866. This device was much better worked out than preceding ones, and more nearly in accordance with the theoretical requirements laid down by Rochas a few years before. The cylinder was vertical with admission valve at the bottom, and means for igniting when the piston was near the lower, or head, end of the cylinder. No exhaust valve was used, but the piston was freely permitted to rise on the exploded charge until it reached the top of the cylinder and the charge exhausted freely into the air. The piston at once fell back, and turned a shaft by a rack, pinion and ratchet. The condensation or cooling of the gases in the cylinder permitted the atmospheric pressure to drive the piston downward in addition to its own weight, and also introduced the new charge below it. When the piston had compressed the new charge enough to support its own weight, ignition again took place, and the action was repeated. These engines were very noisy because of the free exhaust, they caused considerable vibration, owing to the violence of the upward piston movement with no means for balancing or counteracting it, and while better than their predecessors, were still far from being perfect. A goodly number of them were made, however, and put on the market for public consumption.



Section of Otto and Langen engine with free piston. The explosion threw the piston to the top of the stroke, the rack revolving a free wheel clutch. Atmospheric pressure then drove the piston down again, the clutch gripping and turning the shaft

A non-compression engine using flame ignition was patented by W. H. Laubach in January, 1868, and there was some activity in engines of this type about this time, largely because of the introduction of petroleum following the boring of the first, or Drake, oil well in 1859. In July, 1868, B. T. Babbitt, since celebrated as a soap magnate, patented a multi-cylinder engine with electric ignition for compressing air, and in 1871 C. P. Leavitt was granted a patent on an engine of the Brayton type.

Other Patents

In 1854 and also in 1857 Barsanti and Mattenci took out English patents on a gas engine of the free-piston type in which they used electric ignition and a make-and-break mechanism with a storage coil or "multiplier" of the De la Rive type. The drawings of this ignition system are not very plain, but it seems to be a wipe spark secured by a revolving part.

Michigan's 1915 Registration Analyzed

Over 400 Car and Truck Manufacturers Represented

OVER 400 automobile and motor truck manufacturers are represented among the 112,953 passenger and commercial cars registered by residents of Michigan during 1915. The remaining 1892 vehicles reported in the total given by the Secretary of State are registered by residents of Canada, etc. They were included in his total because they are actually registered and in use in Michigan.

A great many of the cars found in this analysis of the registrations by Michigan people were built by manufacturers who have either failed, merged with other companies, or been absorbed. Included in the general total are 902 cars and trucks classed as miscellaneous since they are on record merely as "assembled," "own make," or under freak names.

Of the 112,953 vehicles registered, 111,177 are gasoline cars and trucks and only 1776, or less than 2 per cent are electrics. There are 108,102 American-built gasoline passenger cars and forty-three foreign cars. There are 3150 commercial vehicles, or less than 3 per cent of the total registration, 3032 being gasoline and 118 electrics.

In the analysis it is brought out that 44,113, or over 40 per cent of the 108,102 American-made gasoline passenger cars are Fords. Buick is second with 7749, then comes Overland with 7425, Studebaker with 5014, Reo with 4863, Maxwell 3218 and Cadillac with 2987.

The Rostrum

80 Per Cent of Fuel Not Vaporized

I HAVE just read with unusual interest the question of A. I. A., in your issue of March 2, 1916, on page 422, subject, "Piston Displacement per Mile Measures Consumption."

The writer of that apparently simple question has outlined what in my opinion is the only method the engineers designing gas engines in the future can use if they wish to intelligently ascertain just what the fuel economy of any engine really is, and how far short the actual road performance of the average American motor vehicle is of the practicable and possible miles per gallon, for any given piston displacement, load to be carried, etc.

A. I. A. says his Oakland, model 50, Northway engine has a piston displacement of 346.4 cu. in., etc., and figures the total displacement of gas is 242.65 cu. ft. per mile traveled of his car.

It is true that his engine does actually use the amount of gas he states for each mile traveled regardless of the speed. But one must consider that it takes a gas rich in oil vapor converted into a homogeneous mixture with air, and then transformed into gas, either in the carburetting device itself, or partially therein, partially in manifolds, valve chambers and in the cylinder under the heat of a former charge, the heat of compression, and the heat generated by the spread of flame after ignition. He makes the mistake, however, of assuming that one gallon of gasoline makes but 25 cu. ft. of vapor.

A gallon of 61 deg. Baumé gasoline, at 60 deg. Fahr., either in the laboratory or in a proper gas generator for motor vehicles, will make approximately 240 cu. ft. of oil vapor at approximately 8 in. water tension.

That amount of vapor, mixed with approximately 22 parts air by volume, will, when converted by heat properly applied so as to convert the mixture of vapor and air into dry gas at a temperature higher than the highest boiling point of the heaviest hydrocarbon in the gasoline, give approximately 5500 cu. ft. of gas mixture, having the highest explosive combustibility, under the average compression in the model of engine he mentions, when the engine speed is approximately that able to drive his car at the rate of 20 m.p.h. on relatively level roads.

This, provided the intake manifold and valve chambers are properly designed so as not to waste any of the gas power between the gas generator and the intake valve by expansion. A superheated gas as herein contemplated performs work by mere expansion in the manifold and valve chambers, also in the intake stroke of piston in cylinder, just the same as superheated steam performs work when it expands in the high pressure cylinder of a compound engine, etc.

Now, A. I. A. can readily figure for himself, that his car should run on the piston displacement basis at 20 m.p.h., on fairly level roads, 22.3 m.p.g. At 30 m.p.h. he should run approximately 18 m.p.g.

To give A. I. A. some idea of the power that gas would have, it is enough to say that his car should accelerate from 5 to 30 m.p.h. on high gear in 10 sec.

The gas does not get richer as the speed of the engine increases. But the horsepower to produce the speed increases, so that if a carbureter or gas generator at 800 r.p.m. uses say 55/100 lb. of gasoline per horsepower hour, to develop a certain power to drive the car at that speed, at 30 m.p.h. the horsepower would be considerably greater, but the fuel consumption per horsepower hour would be approximately the same. The difference being in road work, in using more mixture in less time to secure the higher speed than the lower speed.

The trouble with motor cars to-day in the hands of the public, using low volatile gasolines, is that but 10 per cent of the gasoline used is vaporized, 10 per cent partially atomized and 80 per cent of the liquid actually goes into cylinders as raw liquid. There is not time in high speed engines for all this liquid oil to be transformed from liquid to vapor, or gas, before the dead center of the piston, and any flame which develops after the piston starts to fall, adds little if any power to the crankshaft, although it does burn up the oil. To that extent it is wasting valuable fuel oil, due to the low volatility of oils of to-day being used in engines designed for highly volatile oils.

New York. W. P. D.

Two-Cycle Problems

Editor, THE AUTOMOBILE:—Was there a patent ever granted on the two-cycle 2 dia. piston motor? If so, to whom?

2—Would not the two-cycle motor be as efficient as the four-cycle if the cylinder was scavenged with air before admission of mixture, assuming the air to be forced in by some mechanical means?

3—Does THE AUTOMOBILE know of any experiments along this line? The writer has been advised that the Elmore 2 dia. piston motor was a failure, owing to leakage by the piston from the larger diameter to the smaller.

4—Did the Elmore motor have packing rings inserted in the small cylinder to pack against the compression of the larger bore? C. H. P.

Jefferson, Ohio.

—There have been innumerable patents granted to two-cycle two-diameter piston motors. It would be impossible to give a complete list.

2—There is no fundamental reason why this should not be the case.

3—There have been innumerable experiments by a great number of inventors. The majority of two-cycle engines have been lacking in some way because their inventors tried to make them too simple.

4—There were rings on both the large and the small diameter parts of the piston.

Four Most Economical

Editor THE AUTOMOBILE:—We Americans are the greatest automobile manufacturers in the world, but are we the makers of the best automobiles? In my opinion we are not. The tendencies in design on both continents are radically different. Abroad the manufacturers have stuck by the small high-speed four-cylinder engine. Why do the manufacturers in this country build six-, eight- and twelve-cylinder motors? The experts here claim that the high price of fuel abroad is their reason for using the four-cylinder motor. The price of gasoline to the European is of little consequence, for there only the wealthy own machines. You say the public demanded a smooth-running car in which one did not have to change speeds. There is the whole problem. The transmissions in American automobiles are abominable. The slogan of many cars is that we do not have to change speeds. They could not build a gearbox to shift speeds satisfactorily so they stuck on more and more cylinders until shifting was unnecessary. The question is this: Would you prefer two-, four- or eight-cylinders to one more speed in the transmission properly designed?

2—What clearance has the new Marmon between cylinder and piston?

3—What clearance have the Peugeot racing cars between cylinder and piston?

4—What clearance would you advise when fitting aluminum pistons to a small high-speed motor to be used for high-speed work?

New York City. S. G.

—Undoubtedly the four-cylinder car of high-speed type is the most economical if the driver is prepared to shift gears frequently. There seems to be a difference between the characteristics of European and American drivers. The former have no objection to gear shifting while the latter do not like to have to do it.

2—Approximately 6/1000 of an inch.

3—Ten to 12/1000 of an inch.

4—About 2½ thousandths per inch of diameter.

Timing for High Speed

Editor THE AUTOMOBILE:—I have a four-cylinder water-cooled motor 2½ in. bore by 4-in. stroke. I have cleaned and overhauled it this winter. In checking up the timing of the valves I noticed the intake valve remained open until the piston was half way up on compression stroke, so I changed it so it will close when the piston is about ¼-in. past lower dead center. After doing this the valves all seemed to be correct, that is, exhaust opening just before lower dead center and closing just before dead center. Intake opening about ⅛ in. past top dead center and closing at ¼ in. past lower dead center. Now my trouble is this, although the exhaust valve opens before lower dead center on the explosion stroke just as it opens there must be a very large vacuum or something in the cylinder because there is a very small back suction through the exhaust pipe. I have only noticed this in turning the engine over by hand perhaps when she gets to working the explosion will stop this back suction. The intake is a continual suction, no back blow. Perhaps you could give me the exact timing by diagram if this timing is wrong. The motor in high speed is supposed to develop 15 hp. but of course only figures 10.

New York City. S. A.

—Probably the original timing was correct for your engine. Many high speed motors operate best with the intake valve closing very late. If the original timing was in accordance with the maker's setting it will be right and you probably cannot improve upon it.

Fitting Bronze Bearings

Editor THE AUTOMOBILE:—I have a model 17-1909 Buick, which is fitted with full babbitt connecting rod bearings. They require close attention and pound out in very short time. Would a full bronze bearing without babbitt face be advisable? If not, what would you advise?

2—Will you kindly give me the names of a few concerns who would make these bearings?

Genoa, Neb. C. L. A.

—Your experience with these bearings is rather unusual and you will be well advised to make a careful examination of the lubrication system to see that this is operating properly. If this fails to cure the trouble any repair shop will make you bronze bearings with a babbitt face and these are of course stronger than the full babbitt although the latter are most commonly employed in modern engines.

Try Kerosene Mixture

Editor THE AUTOMOBILE:—Would you kindly advise me as to whether the Schebler model L carbureter on my Overland model 59 would handle kerosene as a fuel or not? Would any change be necessary? I have been thinking that I would reduce the tension on the auxiliary air intake valve spring. Would this be advisable or not? I am going to fit a small tank on the dash of the car to supply gasoline for starting.

Vineland, N. J. R. W. C.

—You will very likely find the carbureter will operate well on a half and half mixture of kerosene and gasoline. Some engines run well on this mixture though not all. It will probably need more air. You would be well advised to fit the small tank for starting purposes.

Applying Kerosene to Gas Motor

Editor THE AUTOMOBILE:—To burn kerosene instead of gasoline in a modern gasoline engine what would be the necessary changes to make?

2—Just what effect would the using of kerosene have on the motor and how different from when gasoline is used?

3—Make comparison regarding power, fuel consumption and motor cleanliness.

4—Would it be advisable to use a six-cylinder on a farm tractor instead of a four-cylinder of the same power? State advantages and disadvantages.

De Kalb, Ill. W. B. S.

—A certain quantity of kerosene can be mixed with good gasoline and used in an ordinary carbureter but to burn pure kerosene a special vaporizer is necessary.

2—Usually an engine running on kerosene carbons up more rapidly.

3—There should be practically no difference in power, fuel consumption a little heavier and motor cleanliness inferior.

4—Probably not, the four-cylinder being simpler and having fewer parts.

Speeding Up Buick Model 10

Editor THE AUTOMOBILE:—I am rebuilding a Buick model 10 motor for speed purposes and wish to increase the length of the piston from the wristpin up to give me a higher cylinder pressure. What was the original cylinder pressure of this motor and how much should I lengthen the piston to bring the pressure up to modern requirements?

2—At what speed did this motor develop its maximum power and what was that power?

3—Can you offer me any suggestions to increase the speed and power of my motor?

Marion, Ind. A. E. V.

—It would probably be unwise to increase the compression of your Buick motor as this was designed for the present compression.

2—Model 10 engine developed a maximum of 30 hp. at 2200 r.p.m.

3—For increasing speed, we would suggest the lightening of all reciprocating parts and careful balancing of rotating members. Valve opening can be increased by substituting exhaust cams for inlet cams, and the bottom half of the valve cages can be cut off and the valves seated directly in cylinder head. The magneto timing can also be advanced a little.

Australia Needs Cheap Cars

Stringency of Money Combined with Prosperous Conditions of Industry Creates Market for Low Priced Cars —Country Will Absorb Large Numbers This Year

By THE AUTOMOBILE'S Special Correspondent

THE outlook for the immediate future of the automobile trade in Australia is not a very promising one. The war is costing the Commonwealth $6,250,000 a week, and this has to be paid for by ourselves and not by the Imperial Government, as this party has its hands full with its own affairs. There have been two successful war loans floated in this country, which shows that the wealth of the people is more than anticipated, but this loan, unfortunately as far as trade is concerned, is attracting money that otherwise would have been put into different channels, such as purchasing automobiles. No doubt further loans will have to be floated as expenses keep going.

However, there is one consolation, that is, trade will never go flat while we get good seasons here. The wheat crop this year was enormous, and the same with the wool. The trouble is to shift it away from the country, and the enormous freights that have to be paid does not give the producer the amount of profit he would get in normal times. In fact, the government has commandeered the whole, and so far is only allowing the producer 30 cents a bushel, with the promise that if there is anything left over after the government has finished shifting it to other parts of the world, they will be paid the surplus. It is the producer on the land who is the greatest car buyer.

Mineral Exports Fall Off

On the other hand, there is an immense falling off in the export of mineral wealth, more especially coal. All the mining centers now are very dead indeed, and the purchasing power of the people interested must suffer as a result. Of course, like every war-stricken country, we are burdened with heavy taxation, and this naturally must restrict the purchasing power of the people somewhat.

For the future, though, a good market for the low-priced light American car is assured. At the time of writing freights are $40 a ton, and this, together with other charges, brings the importation cost of the average motor car up to nearly $1,000. These figures include ocean freights, inland freights ranging from $35 to $85, depreciation of English money, exchange assurance and other factors. Thus you will see that the $1,000 car has to be sold in this country at a price something like $2,000.

Practically every make of American car has now found agents in this State, but the older firms do not lose anything by this. The business of several firms has increased by more than double in the last few months, among them being Overland, Hupmobile, Studebaker and Oakland. At present the newcomer, the Dodge, is causing a sensation.

Having regard to the circumstances, the import figures suggest that American manufacturers did not take the fullest possible advantage of the conditions.

Registration of Cars in New South Wales in 1914 and 1915

Return compiled from information supplied by Traffic Department:

	Year 1914	Year 1915

ACCESSORIES

Bergen Carbureter

THIS carbureter, just introduced after tests during nearly five years, is of the constant vacuum and metering pin type, as shown in the illustration. The distinctive feature is the use of a ported piston *P*, which operates within a ported cylinder *C*. No springs or auxiliary air valves are employed. The suction of the engine controls the opening and closing of the air ports, the movement of the piston varying with the speed of the engine. Attached to the piston is a tapered metering pin *M*, which moves with the piston, being suspended from a ball so that the pin moves up and down within the gasoline jet *J*, increasing and decreasing the gasoline aperture. The pin is tapered in relation to the opening of the ports so that the correct proportions of air and gasoline are maintained, no matter how much the engine speed may vary.

When starting, the piston is down and the ports are closed. Air is supplied through the hot air hose *A*, passing through a series of holes *B* in the base of the cylinder, then through the venturi leading it to the top of the jet, where it meets the gasoline. From here the air and gasoline mixture passes through the spray *H* and is deflected into the mixing chamber. This arrangement, in conjunction with the constant vacuum principle upon which the carbureter is based, facilitates starting under all conditions and, after the engine is warmed up, aids carburetion.

After starting, when the suction of the engine has lifted the piston, the gasoline passing up the jet mixes with the hot air, passes through the spray, strikes the baffle plates in the base of the piston and passes into the mixing chamber, where it is thoroughly mixed with the air taken in through the lower ports and further mixed when passing the upper ports.

The only adjustment on the carbureter is made by the lever *L* attached to the gasoline jet by which the jet can be raised and lowered, thus changing the mixture by bringing a different part of the tapered pin *M* into operation. When this adjustment is properly set at any speed the mixture is correct at all speeds. The metal float is of standard construction, gasoline being delivered to the float chamber through a fine mesh strainer.

Some of these carbureters have been in successful operation for a considerable time. The manufacturers claim that workmanship and material are of the best and that the adaptability of the various parts is unusual. List prices are: 1-in., $25; 1¼-in., $30; 1½-in., $35; 1¾-in. $40; and 2-in. $45.—Bergen Carburetor Co., Inc., Long Island City, N. Y.

Pennsylvania Ebony Tread

This new black-tread tire, illustrated herewith, is claimed to offer unusual resistance to cuts, punctures and abrasion, owing to the great thickness and toughness of the tread. The manufacturer guarantees this addition to its line, which includes the Pennsylvania Vacuum Cup tires, for 5000 miles.—Pennsylvania Rubber Co., Jeannette, Pa.

A C Long-Body Titan Plug

This new plug, recently placed on the market, follows A C Titan design and is called the long body ⅞ A C Titan, having the standard S. A. E. ⅞-18 thread but differs from other models in that the body of the plug is considerably longer rendering it particularly suitable for motors in which the plugs are located in a deep recess. It sells for $1.

The A C Titan plug is also made in a long body metric size particularly adapted to foreign cars. Renault has adopted it as regular equipment. The plug is furnished either with regular length of thread or with extension.—Champion Ignition Co., Flint, Mich.

Top Covering for Fords

A top covering ready to attach to any Ford is made of a rubber composition. It takes the place of the old top when it is worn and leaky.—Cray Bros., Cleveland, Ohio.

Airspring Grease Cups

The body of this grease cup is internally threaded and a hollow top screws in air tight. Within a cap is a metal disk which rests on the grease and is pressed down by a light coil spring. Screwing down the cap increases the air pressure in the cup and causes the grease to be fed gradually. Air pressure is assisted by the spring. The cups are of pressed steel and all parts are readily removable for cleaning. Copper and brass finishes may be had, and polished or nickel-plated finishes are extra. Prices, plain, ½-oz., $1; 1 oz., $1.25; 3 oz., $1.50; 6 oz., $1.75.—Hunter Pressed Steel Co., Philadelphia, Pa.

Air Cooling

IT is impossible to read F. W. Lanchester's analysis of the problem of cooling internal combustion engines without a feeling of surprise that so little has been done to develop the air-cooled cylinder type. After abandonment by Lanchester's own concern the Franklin car remained the only air-cooled car in the world, barring very small machines. The early Lanchesters were entirely successful engines, and the Franklin is equally so, yet there are no imitators.

The immense concentration of thought upon the aëroplane engine which is observable at present cannot fail to establish exactly what are the good and bad points of air cooling as applied to engines of all sorts of designs. Whereas data on the subject used to be scarce, it will soon be plentiful, and it is interesting to ponder upon the probable effect on automobile engineering.

It is unquestionable that the water needed by most cars is a nuisance. We are so accustomed to it that the trouble in keeping the radiator full, in preventing it from freezing, in guarding its delicate structure from injury has become second nature. If it can be abandoned so much the better, if we lose no other qualities concurrently.

In these days, when new ideas are being accepted so readily, it seems fitting that the subject of air-cooling should receive its share of attention by automobile engineers. There is now no doubt whatever that automobile engineers are going to be the aeronautical men of the future, at least so far as the power plants are concerned, and this can only mean that the design of aeroplane engines and of car motors will become more similar.

War has proved that the automobile engineers could make the best engines by far; it has completely discredited the aero specialists who claimed that theirs was a special subject, and it is thus impossible to believe that automobiles of the air will not henceforward be closely identified with those of the land.

Engine Temperature Control

AS gasoline becomes of heavier gravity, the need for some automatic means for controlling the temperature in the water system of the modern car is apparent. All sorts of makeshift devices are used for shutting off part of the air that passes through the radiator, so it is a strange thing that engineers have not hit upon a method of regulating the cooling in proportion to the demands of the engine at any temperature.

In summer a larger cooling area is wanted; in winter very much less, and it is surprising that someone has not hit upon a means for controlling this either automatically or manually, just as the heating of the carbureter is controlled.

The attempt to control the temperature of water in cylinder jackets has been very successful, but, having regard to the fact that the air passing through the radiator is the ultimate cooling medium, it would seem possible to obtain the advantages of the thermostat by controlling the air flow instead of the water flow. There is a correct temperature for each type of engine, and anything which assists to maintain that temperature accurately will be an improvement to the car.

Individuality

THE ultimate future of custom body building just now offers an interesting field for speculation. The outstanding fact is that there is a greatly growing demand for special bodies, for automobiles that are distinctive from all others.

There are two possible viewpoints. One is that the present state of affairs is a passing craze which will die away, and that the steady improvement of the stock body will reduce the demand for bodies that are built specially. The other view is that the men who can well afford to have what they want are waking up to the fact that there is a greater pride of possession in a car which is unlike any other in the world, than in a vehicle made to pattern.

If the latter idea is the true one, and it appears the more rational in many ways, then the building of custom bodies is likely to become a very important branch of the industry. In Europe the carriage building trade has flourished exceedingly under the automobile régime; it has even grown, and there seems no reason why the same thing should not happen in America.

Motor Reserve Called Out for Service in Mexico

Los Angeles Corps Ordered to the Border—Five Companies of Volunteers Ready for Service—War Department Buys Fleet of Trucks

Los Angeles, Cal., March 12—Volunteers in the Los Angeles Motor Reserve Corps and the recruits in new corps which are being organized this week are to have a chance to show what they can do as quickly as things begin to happen when Uncle Sam gets into action down Mexico way. The first call for volunteers sent out from Washington came this week to the motor reserve corps of California cities, while the well-drilled Los Angeles corps received notice to depart for the border Wednesday, March 15. These are the men who belong to the battery which has been getting in trim for military service, staging practice maneuvers and trial runs in the vicinity of Los Angeles and San Diego in the last few weeks. In addition two full companies of touring car reserves have been recruited in Los Angeles, ready for immediate service. San Francisco is sending two companies and San Diego early this week completed the organization of a fifth company.

The Los Angeles Motor Reserve Corps is under command of Lieut. Al G. Waddell, staff correspondent for The Automobile. He will keep The Automobile readers informed of the operations of the motor reserves during the Mexico expedition. The entire body of motor reserves will go into the field under command of Capt. H. D. Ryus, winner of the first Phoenix road race.

Truck Efficiency High

The corps led by Lieutenant Waddell is the volunteer motor reserve organized in the United States. In recent maneuvers it was shown that a field artillery train composed of four 2½-ton Moreland, worm-drive trucks, the type so far used, are equal to fifty cavalry horses in moving equipment, not considering that they will cover as much ground in a half-hour's time as a troop train could cover in a hard day's driving. It looks as if Gen. Francisco Villa's sharpshooters will have to contend with a considerable amount of dust when the motor artillery drives in their direction, especially since the government has purchased 54 new trucks.

Watt L. Moreland, manager of the Moreland truck factory, is a private in the motor reserve corps and has been present at the practice expeditions. He will furnish fifty-four expert drivers. The men in all of the volunteer companies have undergone a rigid physical examination. Before the truck drivers are accepted for service the officers examine them in the operation of Moreland trucks.

A 3-in. field gun and twenty men were carried on each of the four trucks which recently made the 132-mile run from Los Angeles to San Diego, and a complete field battery, consisting of the gun, shells and battery wagon, weighing more than 4 tons all told, was transported as well. The gun and caisson were trailed behind one of the trucks. The average speed was 20 miles per hour.

In co-operation with Uncle Sam's aeroplane squadron the motor reserve corps will constitute one of the army's chief adjuncts, in the event of an extended expedition into Mexico. The distances and the sparsely settled condition of the region will require exceeding efficiency in maintaining the lines of communication and in moving supplies. Americans may see American military motors in action at the moving picture theaters in future where they have become accustomed to seeing foreign pictures. Cameramen for the news films can take real instead of "faked" pictures for a while. Lieutenant Waddell will tell the story from week to week.

Determined to conduct the pursuit of General Villa in an efficient and modern manner, the War Department asked for bids on two complete motor truck companies, opening on March 14. Besides the short notice given bidders, the action is also interesting in that not only are the manufacturers requested to furnish the chassis but the drivers and officers as well.

New York City, March 15—Colonel A. L. Smith, the United States Army Depot Quartermaster, has awarded to the White Motor Co., Cleveland, and the Thomas B. Jeffery Co., Kenosha, the contract for furnishing the trucks requested by General Funston for the coming campaign in Mexico.

Colonel Smith said he believed that speed in delivery was the prime factor on which the awards were based, and he attributed the selection of two companies instead of just one to a desire on the part of the Government for an experiment in trying out distinct types of machines.

The proposals were for fifty-four 1½-ton motor truck chassis, two wrecking and supply trucks to be equipped with machines for field repairs, such as a small lathe, a drill-press, a forge and a bench vise, and a selection of repair parts. In addition to these, fifteen motorcycles for the use of corporals and messengers are to be supplied. These trucks will be divided into two companies organized along lines identical with those used for horse companies, there being twenty-seven trucks and one wrecking car in each company.

The men desired to go with the vehicles are one truckmaster at $150 per month, three assistant truckmasters at $125, one mechanic at $125, one assistant mechanic at $100 and twenty-seven drivers at $100 for each company. These men are to be civilians familiar with the operation of the vehicles, and are to be paid by the Quartermastor Corps.

No bodies are asked for; the regulation United States army body, 10 ft. 4 in. long, will be used. The trucks are to be delivered f.o.b. the factory. The regulation United States army specifications for 1½-ton trucks are asked for, but delivery will be one of the prime considerations.

More reliance is to be placed upon these two companies than would at first be apparent, for it is expected that the two truck companies will furnish the entire transportation for the present force of 5000 men, in the expedition into Mexico, between the base of supplies and the troops. Each regiment will have its own company of twenty-seven horse wagons, but the trucks will be the connecting link between all five regiments and the base of supplies.

Colonel Smith, who has seen service in Sonora, states that one truck company of twenty-seven trucks should be sufficient for the entire force for the first four marches of 20 miles per day, after which the second company will be needed. He points out that service in Mexico will be very different from that in Europe today, as the distance which the troops will travel and the amount of marching they will do will be much in excess of that encountered abroad.

It is estimated that the two truck companies will cost about $125,000.

Handle Time Payments for Dealers of Twenty Factories

New York, March 13—The Guaranty Securities Co., Toledo, through which the Willys-Overland Co. a short time ago completed arrangements for the disposal by its dealers of cars on the time payment plan, is about to be reorganized and its scope of operations greatly increased. Under the reorganization plan, the company will be known as the Guaranty Securities Corp., and will be prepared to handle time payment business for the dealers of some twenty different manufacturers. The system under which the corporation will operate is somewhat similar to the general plan outlined in Automobile for March 1, there being no expense to the dealer.

Overland Income $9,870,678

Earns Over 46% on Common After Adding in $1,000,000 Set Aside for Emergencies

TOLEDO, March 13—The annual report of Willys-Overland, Inc., for the fiscal year ending Dec. 31, 1915, which has just been made public, shows a net income of $9,870,687 for the year, after setting aside $1,000,000 as a reserve for contingencies. With this reserve added, the figure is equal to over 46 per cent earned on the $21,000,000 of outstanding common stock after figuring 7 per cent on the preferred stock of $15,000,000. The report also shows a profit and loss surplus at the end of the year amounting to $14,720,550, as against $7,651,931 for the previous year, or practically double, thus evidencing the excellent condition of the concern at the start of its largest production year. During 1915, there was redeemed $250,000 of preferred stock, this amount being included in the surplus account.

The total of assets and liabilities reached $58,908,803 as compared with $43,407,482 the previous year, and in this, the item of good will, patents, trade marks, etc., is still set down at $14,059,932. As an evidence of the plant and real estate extensions of the Overland concern, the increase of the item covering these from $9,127,188 to $16,945,453 this past year is of interest. It shows plant and equipment appreciation of over $7,500,000. The inventories account covering parts and materials on hand also took a big jump from $9,648,745 to $17,752,812.

Comparative balance sheet and report for 1914 and 1915 appear below:

Net after expenses, taxes, repairs, depreciation, etc.	$11,201,255
Reserve for contingencies	1,000,000
Interest	330,577
Net income	$9,870,678
Preferred dividends	322,165
Surplus	$9,548,513
Common dividends	2,229,895
Surplus	$7,318,618
Redemption of preferred stock	250,000
Previous surplus	7,651,931
Profit and loss surplus	$14,720,550

The consolidated balance sheet of the Willys-Overland Co., and subsidiaries, as of Dec. 31, 1915, compares as follows:

Assets

	1915	1914
Good will, patents, trade marks, etc.	$14,059,932	$14,059,932
Real estate, buildings, plant and equipment	16,945,453	9,127,188
Investment in and advances to affiliated companies	680,286	2,251,767
Inventories	17,752,812	9,648,745
Balance due from European agents and domestic selling companies	1,081,770	901,942
Accounts receivable	1,929,757	1,813,656
Notes receivable	2,048,494	1,501,283
Miscellaneous investments	70,475	49,925
Cash	4,023,342	3,928,098
Deferred charges to future operations	316,482	124,943
Total	$58,908,803	$43,407,482

Liabilities

	1915	1914
Preferred stock	$4,483,700	$4,721,000
Common stock	21,000,000	20,000,000
Real estate mortgage assumed	448,269	131,500
Notes payable—bank loans	10,200,000	4,434,476
Trade accounts	....	3,164,820
Accounts payable	4,942,179	1,669,273
Pay rolls and salaries accrued	216,560	46,590
Customers' deposits	451,944	291,760
Taxes and interest accrued	164,426	114,021
Reserve for rebates to customers	424,838	235,485
Reserve for car repairs	30,000	30,000
Reserve for royalties payable	30,000	....
Preferred dividend payable Jan. 1	78,465	82.617
Reserve funds	1,717,873	834,005
Profit and loss surplus	14,720,550	7,651,931
Total	$58,908,803	$43,407,482

3787 Saxons Shipped in 2 Months

DETROIT, March 4—During the first two months of this year the Saxon Motor Car Corp. has shipped 3787 cars or 2237 more than during those corresponding months in 1915. This is an increase in shipments of 144 per cent.

The February shipments totaled 2231 cars or 1387 more than in 1915. In January 1556 cars were shipped or close to twice as many as last year when 850 were shipped.

Chalmers Starts New Parts Building

DETROIT, March 4—The Chalmers Motor Co., has started the construction of a new four-story manufacturing building, 60 x 400 ft., to be known as building No. 2. Only parts for Chalmers models of past years are to be made in that structure. Part of the main floor will be provided with factory offices and store room. With a wing, 50 by 60 ft. and the service building recently completed, this will provide 156,000 sq. ft. of additional floor space bringing the total of the entire plant to about 777,500 sq. ft.

Van Schlegell Hupp V.-P.

DETROIT, March 6—Arthur van Schlegell has been appointed vice-president of the Hupp Motor Car Co. Mr. Schlegell is a well known Detroiter who has been general manager and vice-president of the Michigan State Telephone Co. He will remain as vice-president of the telephone company, but not as an executive.

Parrott One-Wheel Tractor Announced

JACKSON, MICH., March 4—The Parrott Tractor Co., has been formed in this city to make the one-wheel Parrott tractor. The officers of the company are B. R. Parrott, president; Louis Goodhart, vice-president and sales manager and M. N. Stewart, secretary-treasurer.

The concern has started operations in the plant of the old Fuller Buggy Co.

Perlman Rim Corp. Organized

Demountable Rim Inventor Heads $10,000,000 Concern Controlling His Patent

NEW YORK CITY, March 15—Announcement is made to-day of the formation of the Perlman Rim Corporation, under the laws of the State of New York, with a capital of $10,000,000. The company has acquired all of the patents, applications for patents and rights of L. H. Perlman, the inventor of the Perlman demountable rim, which, in various forms, is now in almost general use throughout the world.

While the company has a broad charter, it will, for the time being at least, confine its operations to the manufacture and sale of demountable rims of which upwards of 700,000 sets will be required to meet the demands for the season of 1916.

Strong Financial Backing

Mr. Perlman, the president of the company, makes the following statement:

"The threatened shut down of automobile production incident to the settlement of the demountable rim patents controversy has now been happily averted. The manufacture of automobiles, so far as demountable rims are concerned, will go on as usual and without pause. Infringing rim makers and users will be treated fairly."

The Perlman Rim Corporation is being financed by Mr. L. G. Kaufman, President of the Chatham & Phenix National Bank, who has associated with him a number of prominent and equally influential interests.

The long continued and vigorously contested legal battle culminating in a recent decision by the United States Circuit Court of Appeals, established for the Perlman patent basic rights and carried with it judgment for an accounting against the rim manufacturers of the country under which back damages of upward of $1,000,000 have accrued.

Manufacturers' Meeting at Detroit

Probably no decision rendered by the courts of this country in recent years has created a greater sensation, due to the entanglements resulting therefrom which bid fair at one time to tie up nearly the entire automobile industry.

The announcement of the formation of the Perlman Rim Corporation which carries with it the assurance of early adjustment of all differences will come as a pleasant surprise to the automobile manufacturers who are to-day (Wednesday) in session at Detroit, Mich., in the hope of averting a crisis.

Full Season For Des Moines

Speedway Plans Include Many Events—300 Mile Free-for-All Heads List

DES MOINES, IOWA, March 13—The Des Moines speedway announces the complete program of events for the season of 1916. A racing meet, limited to Iowa entries, will open the season of Memorial Day. The big event of this meet will be the Iowa Derby, for a distance of 20 miles, and with entries limited to Iowa-owned cars. There will be a 10-mile race with entries limited to Des Moines-owned cars. An Iowa Derby of 20 miles will be held also for Iowa motorcycles and a 10-mile race also for Des Moines-owned motorcycles. The entry fee for these events will be nominal only and the size of the prizes will be determined by the gate receipts.

The big event of the year for the Des Moines speedway will be the 300-mile free-for-all on June 28 with minimum speed requirements, a technical committee to determine the qualification of drivers, and a purse of $10,000. Bob Burman, Billy Chandler and Fred Duesenberg are prominent among those who already have entry blanks for the June 28 event.

A non-competitive program will be staged at the speedway on July Fourth. It will be a sort of celebration with exhibition automobile races, aeroplane flights, fireworks and kindred attractions.

An invitation meet on Sept. 4 will end the Des Moines speedway program for the year. This will be in celebration of Labor Day, which falls on that date. The starts will be limited to six in number and invitations will be issued only to drivers who have finished first or second in races on the American Association speedway circuit for the season of 1916. The winners and the management will split the gate receipts, fifty-fifty.

Coffin Heads Industrial Preparedness Committee—Speeds Organization Work

NEW YORK CITY, March 15—Howard E. Coffin, chairman of the committee on industrial preparedness of the Naval Consulting Board, yesterday opened headquarters in the Engineers' Building. Here Mr. Coffin will accelerate the work of mobilizing the industries of the country, comprising almost two-thirds of the world's output for preparedness purposes. The co-operation of the nation's business men is being sought through the Chamber of Commerce of the United States. With the support of the manufacturers the next step will be the gathering of information about 40,000 plants through 240 field directors, a board of five men in each State who are leaders in their professions. This information will be tabulated under the direction of W. S. Gifford, chief statistician of the American Telephone and Telegraph Co., who is the supervising director of field work of the committee.

The idea is that the Government will place small yearly orders for military and naval supplies with each plant to be filled at cost and in the event of war each concern will receive orders based on a 10-per cent profit.

To Handle Federal and Commerce Trucks in New York City

NEW YORK CITY, March 15—The local branch of the Federal Motor Truck Co., Detroit, has been purchased by prominent New York men, who will complete a corporation and will market both the Federal and Commerce trucks in the Metropolitan district. This branch is the last one to be sold, the Federal company having decided more than a year ago to sell all of its branches. After negotiations, Cornelius Vanderbilt, J. B. Ford, Henry Whiton, Edwin Palmer and M. W. Smith, all prominent local club men, were brought together and the deal was made.

Splitdorf Starts Plant Addition

NEWARK, N. J., March 10—Ground has been broken for the new addition to the plant of the Splitdorf Electric Co., this city. This new six-story building will practically double the present production of 1500 Splitdorf magnetos a day, and will add approximately 110,000 sq. ft. in space. The dimensions of the addition are 300 by 60 ft. and the construction will be along the most modern lines of concrete, brick and steel. It is estimated that the present number of employees, 2000, will be increased approximately 33 1/3 per cent.

Two Detroit Plants in Cleveland

CLEVELAND, OHIO, March 12—The H. J. Walker Co. has now removed its entire equipment from Detroit into a plant built for it on the grounds of the Chandler Motor Car Co. The Walker shops handle much of the Chandler company's machining.

A plant for the Briggs Mfg. Co., Detroit, is also being erected on a site adjoining the Chandler factory. In this plant the Briggs Co. will paint and upholster 20,000 bodies for this year's Chandler production.

2,430 Fords in 1 Day—A Record

DETROIT, March 3—The Ford Motor Co. broke its previous output and shipping record Feb. 29, when 2,430 Fords were made and shipped. This is 330 more than the previous high mark.

Four Events Open Sheepshead Bay

New York Speedway Will Have Varied Program of Race Events May 13

NEW YORK CITY, March 15—Four events will open the Sheepshead Bay motor speedway racing season May 13. The feature event will be the Metropolitan trophy, a 150-mile race for cars within the 300-cu. in. piston displacement limit. Entrants will be required to make 90 m.p.h. to qualify, and the race will be limited to 90 min. It is an A. A. A. 1916 championship award event under the new plan of the contest board of that organization for determining racing champions. The trophy will be contested for over three or five years. There will be $15,000 in prizes distributed over seven places, varying from $6,000 for first to $400 for seventh.

The other events are: The 50-mile Queens cup race carrying $2,500 spread over five places; the 20-mile Coney Island cup with $1,500 for five places; both being for cars within the 300-in. limit; and the 10-mile Brooklyn handicap for non-winners, the prize being the Wm. Kemble cup and $1,000 in five prizes. Anyone not taking a prize in the previous events is entitled to compete in this race. These three cups are given outright to the winners.

Big Match Race

The Sheepshead Bay corporation is setting the fashion with short races, another interesting event for the May 13 opening promising to be a match race for 10 miles for a big purse between the three fastest cars in the world.

Albany Court Holds Maker Liable for Defects

ALBANY, N. Y., March 14—A manufacturer is liable for defects in an article which causes injuries to the purchaser, even though the article is purchased through intermediaries, according to a decision of the Court of Appeals, yesterday. The decision is said to establish a new principle in law, for previous court rulings held that manufacturers were liable only for articles inherently dangerous, such as poisons, explosives and firearms.

Suit was brought to recover damages resulting from being thrown out of an automobile purchased a year before the accident. One of the wheels collapsed and it was found that it had been constructed of defective wood and that the defect could have been discovered upon examination before the car left the factory.

S. A. E. Summer Meeting Program

Full Details of Arrangements for Four-Day Trip on Noronic Now Completed

DETROIT, MICH., March 10—Complete arrangements for the mid-summer cruise of the Society of Automobile Engineers, June 12-16, as evolved by the 1916 meetings committee, contemplate the most extensive summer outing the society has yet undertaken. The steamer Noronic, with accommodations for approximately 550, has been chartered, and the four-day cruise on Lake Huron and Georgian Bay embraces Mackinac Island, Collins Inlet and parts of the thirty Thousand Islands, with a complete day given over to picnicking, fishing and sight-seeing through the island.

The four-day cruise starts from Detroit Monday, June 12, at 2 p. m., and ends here Friday, June 16, at 6 p. m. The complete itinerary is:

Monday, June 12—Leave Detroit 2 p. m., Eastern standard time.
Tuesday, June 13—Arrive Mackinac Island 11 a. m.; leave Mackinac Island 6 p. m.
Wednesday, June 14—Arrive Killarney, Ont., 7 a. m. Day given over to picnics, etc.
Thursday, June 15—Leave Killarney 5 a. m.; arrive Owen Sound, Ont., 3 p. m.; leave Owen Sound 7 p. m.
Friday, June 16—Arrive Detroit 6 p. m.

$35 Inclusive

Full details with regard to tickets, reservations, etc., on the Noronic for the four days have been concluded, and boat tickets including meals and berths in all staterooms (ten parlors excepted) are at $35 each for all members. Guests are charged $5 additional. Children between five and twelve, $17.50 each. The ten parlors, which occupy the best positions on the Noronic and afford special facilities, cost $150 each, this including two tickets and meals, etc.

Entire charge of selling tickets and making reservations is in care of the 1916 meetings committee, which has headquarters at 601 Kerr Building, Detroit, where W. H. Conant, treasurer of the committee is in charge. All applications for reservations must be addressed to the S. A. E. at this address. Checks payable to the Society of Automobile Engineers must accompany all orders for tickets and reservations.

Last year the capacity of the Noronic was well taxed on the occasion of the mid-summer S. A. E. session, but this year so great is the interest that it is expected the total accommodations of 550 will be reserved by May 1. In order that S. A. E. members may not be disappointed in securing space, their applications will receive first consideration providing they are in the hands of the committee by May 1. Previous to this date applications will be considered in the following order: First, S. A. E. members and their families; second, applications of sectional associates; third, applications for guests of S. A. E. members; and, fourth, applications for guests of sectional associates. Names must accompany all applications for tickets and reservations.

Daily Program Drafted

Already a tentative program for the four-day session has been drafted by Chairman George H. Dunham and his associates. This program will give approximately the same time to professional sessions as last year, but will afford more opportunity for recreation. Three of the four evenings on the boat will be given over to entertainment furnished by the six sections of the society, to be followed by dancing. Only one evening—namely, Monday—will be devoted to a professional session.

In order to give all in the party aboard the Noronic an opportunity of becoming acquainted, a promenade will be held on the deck Monday afternoon, soon after sailing, and on Friday afternoon, previous to the party disembarking at Detroit, there will be an *au revoir* promenade.

Picnic June 14

Wednesday, June 14, should prove the greatest picnic day in S. A. E. records, as morning, afternoon and evening will be given over to recreation. W. A. Brush, secretary of the 1916 meetings committee and in charge of steamboat arrangements, has arranged with the Northern Navigation Company to afford facilities for fishing, picnicking and excursions through the islands. Provision will be made so those desiring to charter motorboats and launches for the day can do so through the 1916 meetings committee.

President Wilson May Open World's Salesmanship Congress

DETROIT, MICH., March 11—President Wilson has signified his willingness to open the World's Salesmanship Congress, which will be held in Detroit, July 9 to 13. He stated to H. W. Ford, president of the Saxon Motor Co. and vice-chairman of the program committee of the Congress, who made a special trip to Washington to invite him to attend, that he wanted to be at the Congress at least one day and that, providing something unforeseen did not prevent him at the last minute, he would be there either to attend the opening or on some other day.

Many Additions to Detroit Plants

Numerous Parts and Accessory Makers Find Need for Enlarging Their Factories

DETROIT, MICH., March 13—Automobile parts and accessory makers here figure prominently in the list of local concerns which are having additions or new plants erected. Contractors and architects say that they are doing more work for the parts and accessory makers now than in several years. It is quite natural, because with the big increase in car output many of the parts and accessory makers, in order to take care of the increased needs for their products by the car makers, must greatly enlarge their plants and increase their manufacturing facilities.

The American Auto Trimming Co. is adding a five-story building 254 x 95 ft. to its Meldrum Avenue plant. This will provide 120,650 sq. ft. of additional floor space. The working force is to be increased from 500 to at least 700 men, and the top-making part of the company's business will be concentrated upon at the plant on East Grand Boulevard.

The Detroit Auto Specialty Co. has in course of erection a new enameling plant one story high, 300 x 40 ft. When the plant is completed the company will employ 300 or more men.

A three-story addition 92 x 70 ft., providing nearly 20,000 sq. ft. of additional floor space, is being added to the plant of the National Can Co. With the exception of new offices, the entire addition will be an extension of the automobile radiator department, in which it is said that an average of 150 radiators are made now. The working force will be increased from 600 to 800 or more.

At the General Aluminum Brass Mfg. Co. a third floor 160 x 60 ft. is being added.

Nearly 40,000 sq. ft. of floor space is being added to the former Metal Products Co.'s plant, which since last year is a part of the Timken-Detroit Axle Co. A four-story addition 163 x 60 ft. is in course of construction. At least 400 more men will be given employment, bringing the total up to at least 1650.

The Roberts Brass Mfg. Co. is more than doubling its plant. The additions consist of a new foundry, enlarged machine shops and new offices. When completed the plant will front 300 ft. on Fort Street west, 200 ft. on Junction Avenue and 200 ft. on Merrill Street. Most of the new buildings will be two stories high. The foundry will be located on the second floor, alongside of the alley. The company makes, among many other products, special parts for automobiles.

A.A.A. Grants Hudson Records

Revised Record Sheet Covers Conditions of Non-Competitive Records

New York City, March 9—The recent performances of the Hudson Super Six stock car on Sheepshead Bay Speedway, Nov. 25, were incorporated into the official records of the Contest Board of the American Automobile Assn. at its meeting here to-day. The records granted are non-competitive ones, namely, those in which only one car was on the track and occupy a separate division from competition records. It was necessary for the Contest Board to revise its entire schedule of official records and create a non-competitive division. This division covers practically the same field as the present competitive records and includes all classes of speedway distances according to piston classification; 1 mile circular dirt track distances; speedway records regardless of class; straightaway free-for-all records; and stock chassis straightaway records; and 24-hr. records.

Under this new classification the new Hudson non-competitive records granted are:

Stock car non-competitive records—piston displacement 231 to 300 cu. in.

10 miles	7:54.4
20 miles	15:45.8
50 miles	39:30.8

Under the revision of the official record table it will be possible for manufacturers and others to secure non-competitive stock car and stock chassis records as well as non-stock car and non-stock chassis records. The revised record sheet is sufficiently comprehensive to practically embrace all forms of tests that may be expected for several years to come. In the reclassification all existing records of various classes are continued as heretofore. Up to this time there has been some confusion between records made in competition with other cars and those without competition, namely a single car on the track. The board was convinced it was not right to put competitive and non-competitive records in the same division and hence the new arrangement in which all competitive records are classified under Division 1 and all non-competitive records under Division 2. There are arrangements for official fuel economy records, etc.

The further important work of the board was the drafting of specific rules for stock 24-hr. races. There has been a demand for such and already a sanction has been granted for a stock car race June 16 and 17. The new stock chassis rules permit of certain options on the chassis. A stock chassis is defined as:

"A motor car chassis which for the options and requirements listed below can by adding the necessary parts be assembled into a complete stock car."

The options or changes in construction of the chassis permitted are merely those made necessary by safety in driving and others due to removing the body. Thus it is possible to remove leaves from the springs; to change the angle of the steering column for safety purposes and also to make whatever changes are necessary in gearshift and brake levers as well as pedals. Wire wheels are optional and the rear axle gear ratio is such as the standard axle construction will permit of.

Stock Car Restrictions

Certain requirements are added under the new rules: Thus bonnet straps must be carried, fenders and running boards must be removed, and only stock arrangements of ignition, lighting, starting, carburetion, lubrication, cooling, etc., are permitted. Not the slightest change is allowed in any of these systems. The taping of electric connections at terminals, and the taping or wrapping of piping used in the fuel, water, gas or other lines prohibited. The chassis must have complete set of floor boards and standard dash. Wrapping of springs not permitted. In the race the complete lamp equipment is necessary.

Under the stock chassis definition it is naturally permissible to remove the body, running boards, brackets supporting same and other parts which do not serve any direct part in the function of the vital parts, but which are necessary because of the body.

Many Reinstatements

Considerable routine work was carried out at the meeting: Percy Keene, driver, Danbury, Conn. was reinstated; Roy F. Metz, driver, Detroit, was declared eligible for registration; Jos. L. Mazuco, driver, Chicago was reinstated. Terms of disqualification were reduced on the following drivers so as to terminate at dates mentioned: C. D. Klein, July 1; Wm. E. Brown, Sept. 1.

E. H. Shannon, California, was suspended until July 1 for failure to report to officials and failure to start at a California meet Dec. 28.

The Maxwell racing cars recently purchased by Ray Harroun from an outlaw promoter were reinstated on the ground that when these cars were leased to the promoter under the terms of the contract with the Maxwell company the promoter was in good standing. The mile track at Kalamazoo, Mich., was reinstated on recommendation of Clifford Ireland, board representative, Illinois.

Gas Price Hurts Independents

Standard Oil Gets More Gasoline From Crude Oil by Patent Process

New York City, March 10—The rise of gasoline prices has brought a crisis in the affairs of several of the companies among the Independents. There is an old feud between them and the Standard Oil interests, and every cent that is added to the price of gasoline aggravates the difficulty. It is those who are being pinched the hardest who come with an appeal to the motorists of the country. They urge the necessity of a public policy which will act to conserve the supply of crude oil, and to protect motor car users from excessive gasoline prices in the future. Plans are afoot to renew the effort to pass legislation which would allow federal regulation of oil production by the method proposed in 1913 by Secretary of the Interior Franklin K. Lane.

Ask Public Support

Motorists and manufacturers of motor cars are scarcely aware of the power that might be exerted by their combined influence. Men in the oil business, however, who are looking about just now for a life-belt of some sort, have recognized the vital interest which the motoring public has in the problem of gasoline supply. They see too that more crude oil is required for the manufacture of gasoline than scientific methods make necessary. The patented process of refining, controlled by the Standard Oil interests, extracts from two to three times as much gasoline from the oil as other refineries obtain. This is one source of waste. Too many wells in the same vicinity, a condition which arises when there is no regulation exercised in the drilling and production, constitutes another great source of loss by draining the fields too rapidly and reducing the flow of the wells, at least so the experts declare.

Want Congress to Help

In demanding that Congress adopt a plan of conservation to end the exploitation of the country's oil fields, the companies desiring this step are acting not wholly in spirit of generosity toward gasoline users as they have a selfish motive, too. If it were possible to obtain government regulation of oil lands under Secretary Lane's plan, just as the government now exercises control over the pipeline companies as common carriers, the Independent producers would be placed on an equal footing with the Standard Oil organizations, so far as production is concerned. If at the same time the patents controlled by the Standard Oil Co. were to be released to the public, the greatest handicap of the Independent refineries would be removed.

Litigation to force such a step is possible, but in years gone by none of the independent companies has shown an inclination to take the initial steps in the fight. Competitors of the Standard Oil Co. assert that the patent on the Burton process is invalid because it is based on improvements to other patents which have expired.

Whatever the merits of the claim, conditions compel the Independent refineries to use two hundred barrels of crude oil oil to produce 40 gal. of gasoline, while the Standard Oil refineries would obtain the same amount of gasoline from 100 gal. of the same quality of crude oil. The burning oil and fuel oil, which are the other products of the still, must be disposed of also, though both are produced in quantities exceeding the normal demand. Thus while gasoline sells at high prices and is scarce, the burning oil and fuel oil are over-plentiful and sell at low prices. Any profit realized on the crude oil must be derived from the gasoline, which is one of the important factors in raising prices. Little or no profit can be obtained from the sale of fuel oils that are produced from high grade crude. This is due to the fact that fuel oil must be sold at a price which is equivalent to, or less than, the cost of coal that would yield the same energy in calories.

The Burton process is commonly known as the pressure-still process and the method is known as "cracking." The government appropriated a sum for experimenting in the methods of refining crude oil three years ago. The Rittman process has been worked out and placed at the disposal of all refineries. An Independent jobber makes this comment:

"One-third of the amount of crude oil that is now used would supply the market for all requirements if all the heavy ends were run through pressure stills. This would have the effect of reducing the price of crude and lowering the cost of all products. The government has made a step in the right direction in the Rittman process, but it is a failure, all reports to the contrary notwithstanding. Even if the method were practical it has not been developed to the point where it can be used. No refineries are using it, and none will under the conditions laid down by the government, which require parties using the process to bear all the expense of developing with no means of reimbursing themselves and they must also give the result of their discoveries to others. This is all right in one way, but it has the effect of making every one hold off waiting for some one else to stand the expense of trying out the method."

Record for Unfilled Steel Orders

Number of Tons on Order Exceeds Previous Highest—About Double Normal

New York City, March 10—In its last monthly statement the United States Steel Corporation reports unfilled orders on its books as of Feb. 29 last of 8,568,966 tons. This compares with 7,922,767 tons on Jan. 31, an increase of 646,199 tons, and with 4,345,371 tons on Feb. 28, 1915.

The total of 8,568,966 tons on the books establishes a new high record, and exceeds by 79,248 tons the previous topmark of 8,489,718 tons on Dec. 31, 1906. At that time, however, there was considerable duplication in compiling the orders because of the fact that business taken by one subsidiary which had to depend upon another for part of its supplies, was included for both amounts. This feature has been eliminated, however, and the orders on the books of the corporation at present will exceed those of the previous high mark by a much larger total if it were possible to eliminate the duplications in 1906.

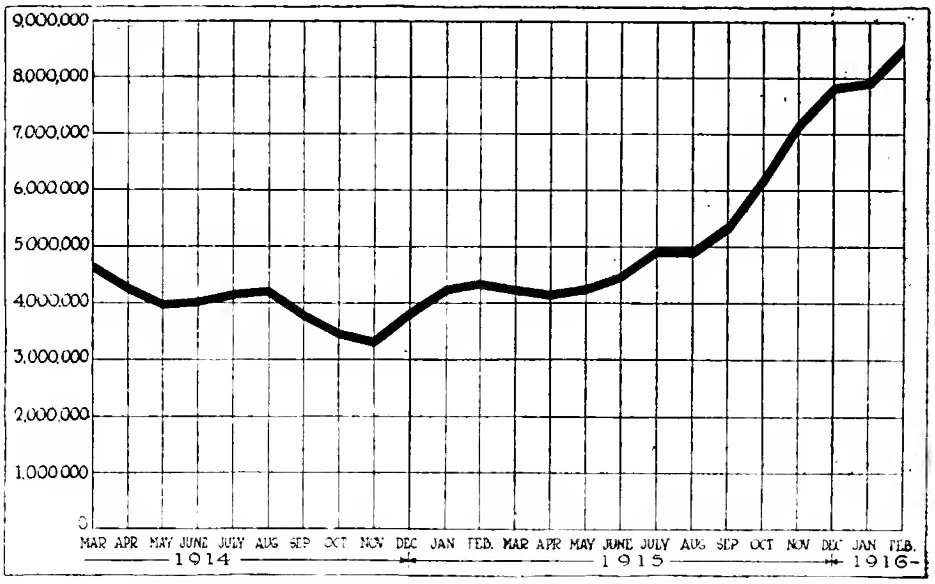
The increase of more than 646,000 tons was larger than had been generally expected. Before the statement was issued the estimates varied from gains of 250,000 to one or two as high as 600,000 tons, but a belief prevailed that the higher figures were too optimistic. It had been generally known that the orders received by the Steel Corporation during February were considerably above those of the previous month, and also that the officials of the company were more discriminatory in accepting business than ever before in the history of the concern.

That, in view of these conditions, such a large increase was recorded was, therefore, considered remarkable. The fact that the present bookings are all firm orders and not contracts against which specifications have been made, therefore allowing cancellations, also is significant.

During February the Corporation established more than one record. It is believed that never before since its organization has the company been booked so far ahead. A considerable tonnage apparently was taken to be filled during 1917. It has been known that some subsidiaries had sufficient orders on hand to keep them operating at capacity during the remainder of 1916, and in view of this fact it can be expected that further business for next year's delivery will be taken during March.

So far this month the orders received compare favorably with those of February, it is unofficially stated. The buying by railroads, while not taking the first position so far as steel consumption is concerned, is receiving the bulk of the attention of the steel makers. When it is recalled that the carriers have placed orders for delivery in the first quarter of 1917 for more than 125,000 tons of rails, it can be seen that a large amount of business can still be expected from this source.

Excellent net earnings of the Steel Corporation for the remainder of 1916 are now practically assured. Estimates ranging to as high as $280,000,000 for the entire year are being made, but these, it must be admitted, are merely guesses. No one can forecast as early as this what the Corporation will show at the end of the fourth quarter, but it seems fairly safe to say that with the large amount of business on hand and the probability of further advances in the prices of various products, the Steel Corporation will establish new records in the succeeding quarters of 1916.



Variation in Unfilled Steel Orders (Tons) During Last Two Years

Mexico Will Be Good Market

Good Roads Planned Throughout Mexico—Trade Expansion Will Demand Trucks

LAREDO, TEX., March 10—The automobile, tire and accessory business in Mexico shows indications of a marked revival, according to information received here from reliable sources. When business fully opens up it is expected that an unprecedented demand for automobiles, motor trucks and delivery cars of American manufacture will be mainifested. The trade in tires and accessories has already reached considerable volume, and it is increasing gradually. Dealers in Laredo expect to get their full share of this Mexican business, along with the automobile and accessory concerns of Eagle Pass, Brownsville, El Paso and San Antonio.

Five Years Closed

It is practically five years since Mexico was eliminated as a market for automobiles and other motor vehicles. At the time the revolutionary period in that country was inaugurated practically all of the leading automobile manufacturers of the United States were represented by agencies in the City of Mexico, Monterey, Aguas Calientes, Vera Cruz and other of the larger cities of the republic. Garages and dealers were located in all of the principal cities, and large stocks of tires and accessories were carried. In those days the trend of the demand was for the higher priced French cars, and in the City of Mexico more automobiles of French make were to be seen upon the streets than of American manufacture. A very large part of the tires and accessories came from France, Germany and England.

While there has been some replenishing of automobiles in Mexico during the last few years, and particularly during the past few months, it is still a virgin field for this class of trade. Most of the cars that have been shipped to Mexico from Laredo and other border towns recently were for military uses and to replace the old, worn-out motor vehicles that saw hard service during the revolutionary period. The demand now extends to private customers to a large degree. In this connection it may be well to mention that the prevailing idea in the United States seems to be that the people of Mexico have exhausted or lost all their wealth by reason of the trials and tribulations through which their country has passed. This is an erroneous impression. While it is true that many men there have had their fortunes badly depleted, there is still much actual cash in the country and it is being placed in circulation as political conditions continue to show improvement.

In the matter of being in a position to quickly supply the needs of the Mexican trade for cars, tires and accessories, the dealers of the towns of Laredo, Eagle Pass and El Paso through these open gateways have a distinct advantage over possible competitors in towns farther removed from the border, it is claimed. As a usual thing the buyer in Mexico wants quick delivery. Not long ago the Laredo Auto Sales Company filled one order for two carloads of tires and tubes for delivery to Yberra & Co., a commission brokerage concern in the City of Mexico, which amounted in value to $25,000 gold.

It is stated by dealers here and at Laredo that there is a good demand for second-hand automobiles for shipment to Mexico. The fact that that country is now short of good horses, and that many people have no means of getting about in carriages, as formerly, is one of the elements that enter into the growing demand for automobiles.

All automobiles and other motor vehicles, as well as tires and accessories, which are sold by dealers here and at other border points are paid for in cash or New York exchange before the shipments are sent across the Rio Grande.

During the last few weeks agencies for the sale of American automobiles have been established in Monterey, Torreon, San Luis Potosi, Tampico, City of Mexico and a number of other larger cities of Mexico. Quite a number of garages have also opened.

Large Trucks Ordered

Some of the larger mining companies and industrial concerns operating in Mexico have placed orders recently for a number of large trucks, and some of these shipments have already gone forward. It is believed that the sale of motor trucks in that country will reach big proportions, inasmuch as they are known to be specially adapted to the heavy hauling which is required in the mining camps and manufacturing centers.

The Mexican duty on automobiles is 66 cents gold each for the first 250 kilos of 2 1/5 lb. each. 55 cents for each of the next 500 kilos, and 45 cents for each of the remaining kilos.

It is said here that it is the plan of "First Chief" Venustiano Carranza and his de facto government to inaugurate an energetic and extensive campaign for the construction of good highways in various parts of Mexico as a part of the general plan of his administration for public improvements. Besides giving employment to many men of the poorer class, the building of roads will be the direct means of bringing about the development of the country.

Colorado Shales Rich in Oil

May Soon Be Worth the Cost to Extract Oil by Distillation

WASHINGTON, D. C., March 13—In view of the ever-increasing demand for gasoline and the increase in price of crude oil, it is important to know, according to a report made public to-day by the United States Geological Survey, that an almost inexhaustible supply of oil may be obtained from the shale of northwestern Colorado, northeastern Utah and southwestern Wyoming. This shale contains materials which, when heated, may be converted into crude oil, gas and ammonia. The high cost of distilling oil from shale as compared to the cost of producing oil from wells has thus far prevented the development in this country of such an industry and may continue to prevent it for some time, but sooner or later this great source of supply will be utilized to supplement the decreasing production from the regular oil fields.

According to the Geological Survey report, the oil derived from the shale is similar to that which is being produced from wells in the United States at the rate of more than 250,000,000 barrels a year. When refined by ordinary methods the shale oil yields an average of about 10 per cent gasoline, 35 per cent kerosene and a large amount of paraffin. The yield of gasoline from the shale may probably be largely increased by the use of refining methods especially designed for that purpose. The gas, which is a very good illuminating gas, will perhaps be sufficient to furnish all the heat required to distill the crude oil from the shale.

The ammonia is a most valuable byproduct of the distillation and may be utilized in the manufacture of commercial fertilizer or other nitrogen compounds, as the market demands. The United States Geological Survey has examined large areas of the shale in Colorado, Utah and Wyoming, and has made many distillation tests. Some beds of shale that are several feet thick will yield more than a barrel of oil to the ton of shale, and one bed 6 in. thick will yield more than two barrels of crude oil to the ton of shale. One ton of this shale should therefore yield nearly 10 gal. of gasoline by the present commercial methods of gasoline extraction, and larger yields may be made possible by new methods.

Little attention has been paid to this shale, because the quantity of petroleum produced from wells in the United States has been sufficient to satisfy all demands; but for more than fifty years the oil shale industry of Scotland has been a very important one. In a recent year more than 8000 men were employed in the industry in that country, yet the average yield of oil per ton of shale was much less than that which appears possible from the shale of Colorado and Utah. It is estimated that in Colorado alone there is sufficient shale, in beds 3 ft. or more thick and richer than the shale being mined in Scotland, to yield 20,000,000,000 barrels of crude oil, from which at least 2,000,000,000 barrels of gasoline may be extracted by ordinary refining processes.

As was stated in the recent reply of Secretary Lane to a Senate resolution on the subject of gasoline: "The development of this enormous reserve simply awaits the time when the price of gasoline or the demand for other distillation products warrants the utilization of this substitute source. This may happen in the future. At all events these shales are likely to be drawn upon long before the exhaustion of the petroleum fields."

Gold Paint for Automobiles

Los Angeles, Cal., March 11—When Mr. F. E. Runner, who recently arrived in Los Angeles from Billings, Mont., ordered a Franklin car last summer, he gave instructions that it be painted a gold color, his idea being that that was the best color to disguise the tint of Montana dust. Experience during the past few months has demonstrated the soundness of his idea, and many of his friends have since had their cars painted the same unique color.

Canadian Dealers May Join American Assn.

Chicago, Ill., March 9—At a meeting of the board of directors of the National Automobile Trade Assn., Feb. 26, held at the headquarters, 208 South La Salle Street, Chicago, it was voted to allow the garagemen and dealers of the Dominion of Canada to become members. This action was taken as a result of many requests from Montreal, Toronto, St. Johns and Hamilton.

Kankakee Co. to Make Six-Cylinder Car

Kankakee, Ill., March 12—Chiniquoy Brothers and Parker, is the name of a new firm just organized in Kankakee, which will market a six-cylinder, five-passenger automobile with standard parts, the latter to be assembled in Kankakee and put together with certain parts to be manufactured in that city. The company has been corresponding with manufacturers of engines and other supplies and contracts are now being written sufficient to cover a good-sized output.

Texas Farmers Plant Peanuts

Poor Wheat Crop Offset by Other Activities—Agriculture in Good Financial Condition

Austin, Tex., March 12—Notwithstanding the fact that the crop-growing season, which is now fairly opened in a large area of the State, is not as promising as the farmers would desire, due to a lack of rainfall in central and south Texas, the demand for automobiles in the agricultural districts keeps up remarkably well. In some of the towns dealers are far behind in filling orders.

Preparations are going forward for planting a big increase of acreage of cotton over that of last year. It is estimated that this increase will amount to fully 15 per cent. The winter oats and wheat came through the cold weather months in such bad shape that thousands of acres of these crops have been plowed up and the land prepared for planting in cotton. Farmers are not paying much attention to the advice of bankers and others that they reduce their cotton acreage this year. The high prices that were obtained from last season's crop are an alluring inducement to engage in the industry to the full limit.

Peanut Industry Booming

The peanut industry has suddenly sprang into much prominence in Texas. It will take rank this year as one of the standard crops of the State. This is due to the fact that many of the cottonseed-oil mills have installed cold presses for the utilization of the peanuts in the manufacture of oil and cake. In every locality where there is an oil mill the farmers are being encouraged to grow a large acreage of peanuts this year.

The livestock industry continues to be in an exceedingly prosperous condition. In some parts of the ranch territory the range is very dry and an unusually large amount of feeding has had to be done to carry the animals through the winter. Many herds are being fattened on silage. Nearly all of the stockmen now grow enough forage upon their ranches to supply an abundance of foodstuff for their cattle.

Building activities in the different cities and towns of the State are now being carried on upon a larger scale than for several years. This is shown by the building permits that have been issued.

Public improvement bonds, both county and municipal, have a higher market value than ever before known, and this fact is causing a veritable boom in civic improvements of various kinds and the construction of good roads. The installation and improvement of public utility plants is receiving much attention. The development of the electric power field in this State has made wonderful progress during the last several months, and important extensions of the power transmission lines are to be made during the present year.

It is the belief of the banks that the farmers will require less assistance in the way of money advances to grow their crops this year than ever before. For the most part the agricultural element of the State is in splendid financial condition. The good prices that were obtained for cotton, livestock and other products placed the average farmer well to the good. The condition is reflected by the unusually large deposits in the country banks.

Bill Regulating Jitneys Passed

Trenton, N. J., March 9—The bill regulating jitneys in this State and introduced as a committee substitute for the Kates bill, also regulating jitneys, has been passed. Opponents of the bill argued that its passage would clear the State of jitneys because the terms of regulation are so onerous. Particular exception was taken to the requirement for indemnifying bonds, though it was subsequently explained that the State jitney organization has already made plans to organize an insurance company to provide bonds for its members.

Governor Fielder signed the amendment to the traffic act of 1915, which gives pedestrians the right of way over vehicles in thickly populated communities and repeals the section of the law providing that any person crossing a street where there is no crosswalk does so at his own risk.

Gray & Davis Laboratory in Detroit

Detroit, Mich., March 12—In order to afford maximum co-operation to automobile manufacturers in Detroit and vicinity, Gray & Davis have established an engineering laboratory at 1602 Woodward Avenue, Detroit. In the past, all engineering problems connected with electric starting and lighting have been worked out at the Boston plant, but under the new plan, automobile designers who now use, or are about to adopt Gray & Davis equipment, will have the services of the Detroit laboratory at their disposal.

The laboratory will be under the management of C. M. Tichenor, long associated with Gray & Davis, both as engineer and factory superintendent. Mr. Tichenor will be assisted by capable engineers. A complete line of Gray & Davis systems are part of the laboratory equipment and these units will be available for instant installation on various engines, thus expediting all experimental work on new jobs.

Three New Delage for Speedways

Harry Harkness Now Has Lyons Grand Prix Racing Cars

NEW YORK CITY, March 13—Harry S. Harkness will compete this coming season on the speedways with the three Delage cars which were driven by Duray, Bablot and Guyot in the French Grand Prix at Lyons in 1914. The three cars arrived in New York last week and are now being overhauled and fitted with new bodies. Carl Limberg, who will manage the team, will drive one of the cars. This team ought to be one of the most important competing this year, as the cars have been run in the one race only. The motors are peculiar in that the valves are operated positively in both directions, being closed by the cam as well as opened. In the Grand Prix the Delage cars did not do very well owing to some unfortunate adjustment having been made the night before the race. Bablot held the record for a lap over the Lyons circuit in practice spins previous to the race and it was the general opinion among French sportsmen that the Delage cars were faster than the Peugeot. There is no doubt whatever that if the three cars had shown the same form in the race that they had already exhibited in the previous practice trials that it would have been possible to push the victorious Mercedes very hard indeed.

Jacksonville Show Pleases Bankers

JACKSONVILLE, FLA., March 10—Florida's first automobile show with thirty-four different makes of cars and trucks, closed to-night in this city. Success marked it from every viewpoint and was in many ways a stimulant for business in the Southeast. The show opened on March 5 and was held in a specially constructed building in Confederate Park, making it the first outdoor automobile show of 1916.

The biggest season in this State for automobile men is predicted by Florida bankers, who are very optimistic. At the present time there are a million tourists in this State and in the local banks alone $25,000,000 is on deposit. Business conditions have improved lately. Though some of the industrial mainstays have been hurt by the war, a general improvement has set in lately. Florida industries consist of turpentine, rosin, phosphates, agriculture and lumber. The first three have been slackened up by the war. Turpentine, however, has picked up lately with its domestic business. The citrus fruit market has been productive and the lumber industry is improving. There is a $1,500,000 potato crop in the State and the tomato crop is in a thriving productive state.

With only 14,000 cars in this State, the show has naturally increased interest in the automobile. Banks are not looking with as much disfavor as they did some time ago on the automobile dealers' paper.

As to the demand in Jacksonville and the surrounding territory, the medium-priced car selling from $800 to $1,500 is most in demand. The local purchasing public is looking for power in its cars due to the heavy sands that must be negotiated. The city is lax on improved streets and in the by-ways leading off the main streets there is sand so difficult to go through that the majority of cars have to shift into low gear.

Locomobile Wins Carbureter Suit

BRIDGEPORT, CONN., March 11—The United States Circuit Court of Appeals has just handed down a decision which reverses that of the Lower Court, which sustained Joseph N. Parken's suit against the Locomobile Co. of America for infringement of his patents for a carbureter.

The patents declared to be infringed by The Locomobile Co. of America cover the use of auxiliary air valves regulated by two springs successively coming into use to automatically meet the requirements of low speed and high speed and at the same time independently adjustable to meet the needs of special conditions.

The main defense on the part of The Locomobile Co. was that the invention was not one, in fact, that the construction was known and had been used before and that it was a natural development of the carbureter art.

It was shown at the trial that a number of persons were working independently on the problem which the plaintiff claims he first solved and that the ideas, possibly the idea of springs, independently adjusted, which occurred to the makers of automobiles were put into form and tried out not only by the inventors themselves, but were given trials by the general public.

In conclusion, the Court of Appeals maintained that, "The improvement based and dependent on the first patent and which simply consisted in controlling the adjustment from the operator's seat, is lacking in invention. The decree is therefore reversed and the case will be remanded with instructions to dismiss the bill."

Denby Pres. Detroit Board of Commerce

DETROIT, MICH., March 14—Edwin Denby, treasurer of the Hupp Motor Car Co., and of the Denby Motor Truck Co., was to-day elected president of the Detroit Board of Commerce.

Harroun Building Twelve

Will Try Out Aviation Engine in Racing Car Chassis—250 H.P. Expected

CHICAGO, March 4—Ray Harroun, one time International Speedway champion, has become the owner of the three big Maxwells which have been campaigned for two seasons. These are the predecessors of the smaller Maxwell racing cars now in Indianapolis. Along with the cars themselves, Harroun has acquire the tools, jigs, patterns and so on which will be used in manufacturing his aviation motor.

First of the aviation motors according to Harroun's plans is a 250 hp. engine of twelve cylinders and will make its first appearance in the racing car Harroun is building. In a letter to *Motor Age* Harroun says:

"I have purchased all of the Maxwell race car equipment, including drawings, tools, jigs patterns, and all spare parts on hand, also the three 450 cu. in. racing cars.

"It is my intention to apply this tool equipment, patterns, etc., to the manufacturing of my aviation motor which will be largely along the lines of the racing car motors, with the exception that they will be of the twelve-cylinder variety. The first one will be 250 hp., which is the one I will try out on the free-for-all racing car which I am building.

"I will sell the 450 cars just as soon as I can find customers for the same—these have been recently overhauled and are now in first class shape.

"I am negotiating with parties in California for the purchase of two of these cars and it is quite possible they will be seen at the Corona race."

Big Lamp Merger Planned

DETROIT, MICH., March 13—While negotiations are pending between the Edmunds & Jones Mfg. Co., automobile lamp makers here; the Canadian Lamp & Stamping Co., Walkerville, Ont., and the Chicago Electrical Mfg. Co., Chicago, with the object of a merger which is to be eventually named the Edmunds & Jones Corp., George E. Edmunds, secretary-treasurer of the Edmunds & Jones Mfg. Co., states that the deal has not yet been completed, and that statements published locally regarding the combine are as yet premature.

Local financial circles have it that a syndicate of New York brokerage houses, consisting of Hornblower & Weeks; White, Weld & Co., and Merrill, Lynch & Co., are offering participation in the marketing of $1,000,000 in 7 per cent cumulative preferred stock and 40,000 shares of common stock which may go on sale at $40 a share, and which is to constitute the capital stock of the new corporation.

This merger, if consummated, would be one of the largest automobile lamp manufacturing enterprises in the world. The Edmunds & Jones Mfg. Co. has been in business in Detroit since 1904, and is capitalized at $500,000 and has always been one of the best known automobile lamp makers in the industry.

Stubbs Premier Sales Mgr.

INDIANAPOLIS, IND., March 9—P. S. Stubbs has been appointed sales manager of the Premier Motor Corp., this city. Mr. Stubbs became assistant sales manager of the Knox Automobile Co., Springfield, Mass., in 1906; a year later he joined John N. Willys, serving as sales manager and director of the many enterprises undertaken by Mr. Willys—among them the Overland, Marion and American.

When the Hudson Motors reorganized its personnel in 1910 he joined its sales organization and has been associated in an executive capacity with that company as Eastern manager, assistant sales manager and later as Pacific Coast distributor.

Goodrich Increases Number of Directors to Eighteen

AKRON, OHIO, March 12—The B. F. Goodrich Co. has declared a regular quarterly dividend of 1 per cent on the common stock, payable May 15 to stock of record May 4.

The following have been elected directors of the company to fill the increased places on the board, and one to fill the vacancy of A. H. Wiggin, resigned: W. O. Rutherford, A. B. Jones, Dr. W. C. Geer, H. E. Joy and H. K. Raymond. This makes the present number of directors eighteen.

At a meeting of the directors, officers of the Goodrich company were re-elected. They are as follows: President, B. F. Work; secretary, C. B. Raymond; treasurer, W. A. Means; and sales manager, H. E. Raymond.

At a special meeting of the stockholders of the company, the authorized preferred issue was reduced from $28,000,000 to $27,300,000.

3025 Ignition Systems Shipped by Atwater-Kent March 1

PHILADELPHIA, PA., March 11—A shipment of ignition systems, equaling one-half of its entire year's output 5 years ago, and amounting to 3025 systems, was made by the Atwater Kent Mfg. Works, on March 1.

F. T. C. Active for Gasoline Supply

Commission Speeds Up Inquiry Into Subject—Congress Urged to Action from All Sides

WASHINGTON, D. C., March 14—Federal activities to determine causes for the high price of gasoline and to effect a reduction may be briefly summed up as follows:

Federal Trade Commission making thorough investigation of facts, considering this the most important work before them. The commission will make a report before Congress adjourns.

The Director of Mines states that the Rittman process was offered free to all producers and refused on account of a clause which prevented monopoly.

The Bureau of Mines has issued a bulletin describing the Rittman process to minimize the cost of refining.

Representative Steenerson is drafting a new bill to present to Congress which he says will "prevent the high cost of gasoline."

Sentiment in Congress shows that any measure for relief will be heartily indorsed by members.

Members of Congress are being besieged to take action by letters from all parts of the country.

While it will be impossible for the Federal Trade Commission to take any drastic steps or make any specific report for some weeks, Commissioner Harris said to-day that they were urging all their agents to make as quick and thorough an investigation of all conditions as soon as possible, and that all the men who could possibly be called upon for this work have been sent into the field. He expects that it will be at least six weeks before these agents can return and make their reports.

Congress is ready to take prompt action for relief of the automobile users, for every member of Congress is being besieged by constituents to take action. The manufacturers of motor cars are deeply concerned and say that already their trade is suffering seriously because of the heavy increase in cost of running a car. Some of them have written to members of Congress stating that if the present prices for gasoline are maintained it will ruin their business. In response to these urgings Congress as a whole is prepared to give a friendly ear to any adequate measure for relief.

The collection of statistics concerning the production and use of gasoline is asked for in a bill introduced in the House by Representative Carter of Oklahoma. The bill would authorize the director of the Bureau of Mines to collect and publish the statistics, which should include facts concerning the production of crude petroleum, as well as facts concerning its manufacture into gasoline, and the best obtainable facts concerning the marketing of gasoline.

Ford May Make Gasoline

Henry Ford will get into the fight on the high cost of gasoline. This announcement was made to-day by Congressman Randall of California, who appealed to the manufacturer to aid in promoting processes for the cheaper production of gasoline.

Ford, Randall said, believes the Rittman process, discovered in the United States Bureau of Mines, will result in greatly reduced cost to the consumer. Rittman is now experimenting with another process to produce more gasoline from kerosene, Randall said. Ford in a letter to Randall said: "The solution of the gasoline problem is an urgent matter; if one attempt fails, the quickest way to get a solution will be to commence with another. Although I may not be able to take up the Rittman process at once, in response to the appeal of Congressman Randall, after the present test is completed I may go into it thoroughly."

Chevrolet Bros. To Race Three Frontenac Cars This Season

DETROIT, MICH., March 12—Louis Chevrolet, having completed experiments with the aluminum engine he made last fall, is now completing three brand new racing cars for competition on the speedways during the present year. The cars will be known as "Frontenacs" and will be driven by Louis, Arthur and Gaston Chevrolet.

It is expected that the first of the three will be ready early in May and will appear first on the Sheepshead Bay speedway. The other two should also put in an appearance at Indianapolis.

Chevrolet is building every part of the cars to his own design from engine to rear axle, and expects to get a minimum of 125 hp. from each motor. Light weight has been an aim, and the completed car is scheduled to turn the scale at not more than 1750 lb.

Embargo on Hides in South Africa

CAPETOWN, March 14—The exportation of wet or dry salted hides has been prohibited except to the United Kingdom. The shipment of sun-dried hides of light weight is permitted conditionally.

Royer Wheel Co. Formed

AURORA, IND., March 10—The Royer Wheel Co., Aurora, Ind., has been incorporated with $150,000 capital stock, for the purpose of manufacturing automobile wheels, both for pleasure cars and trucks.

I. A. L. Representatives Indicted

Uniontown Grand Jury Charges Conspiracy and False Pretences—Other Arrests

UNIONTOWN, PA., March 13—The grand jury has indicted A. C. Bidwell, president of the International Automobile League, Buffalo, N. Y., and two of its representatives, Harry Ames Van Auken and F. A. Chapman on charges of conspiracy and obtaining money under false pretences. Chapman is under arrest here and entered a plea of guilty today. He was placed on parole for two years and released. Van Auken was arrested in Valdosta, Ga., and will be brought here for trial.

The Standard Automobile Garage, this city, charges that Van Auken, exhibiting power of attorney signed by A. C. Bidwell and an Illinois Surety Bond, agreed to furnish an Illinois Surety Bond in the amount the garage would pay for a jobbers' contract issued by the I. A. L. However, upon accepting the contract, which purported to enable the garage to purchase accessories and supplies at from 10 to 33 1/3 per cent of the manufacturers' wholesale price, the bond which was returned was not an Illinois Surety Bond, but a bond of the I. A. L. which was almost an exact imitation of an Illinois Surety Bond in appearance and phraseology.

An investigation by the garage proved, it states, that the League has no contracts with manufacturers of standard supplies and accessories. The League denied Van Auken's authority to promise that it would furnish tires, accessories, etc., at the discounts he promised, in spite of the power of attorney he carried. It is stated that several other dealers in accessories and supplies in this vicinity were also induced to sign contracts.

Blames the League

Richard H. Lee, chairman of the A. A. A. legislative board and president of the Cleveland, Ohio, Automobile Club states in the *Ohio Motorist*, the club organ:

"Owing to the great number of individuals throughout the United States who have at one time or another contributed to the International Automobile League, Inc., of Buffalo, N. Y., considerable interest will be displayed in developments at St. John, New Brunswick, Canada, where two agents of the International named Harold Cottrell and Roy Grey, are under arrest charged with receiving money under false pretences.

"The attorney general, upon the opening of court, moved to have the prisoners, who were represented by counsel, immediately enter a plea of guilty. They were not prosecuted on the other ten counts charged against them. The judge suspended the passing of any sentence and let the prisoners go on a recognizance of $1,000 each and warned them that they must refrain from acting as agents of the International Automobile League.

"The attorney general stated that he felt justified in taking this course in suspending the sentence, in view of the fact that the public welfare would be sufficiently served by preventing the operation of the International Automobile League of Buffalo in this territory; that although the prisoners had made improper and untrue representations, they were to a certain extent victims of the system pursued by the parent company at Buffalo for the purpose of getting money from the public without intention to give an honest return for it."

Brookfield, Rock Falls President

STERLING, ILL., March 12—Galt Brookfield was elected president of the Rock Falls Manufacturing Co., this city at a meeting of the board of directors this week, succeeding C. R. Hardy, resigned. The new president has been connected with the sales department for many years, and is the son of the founder of the company. This concern has been engaged for a number of years in the manufacture of motor hearses, motor ambulances and other motor vehicles.

S. A. E. Sections Have Busy Week

NEW YORK CITY, March 14—Detroit and Cleveland sections of the S. A. E. both expect to hold big meetings this week. J. G. Perrin will discourse to the Detroiters on the past, present and future of rear axles, tracing the problems appertaining to them and paving the way for an active discussion. In Cleveland, C. F. Kettering will read a paper on the Chemistry of Combustion. Mr. Perrin is particularly adapted to handle his subject, having had so great an experience in the industry, culminating in the chief engineership of the Timken Detroit Axle Co. Mr. Kettering is equally a master of his subject, which has a distinct bearing upon the problems of an ignition expert. The Detroit meeting takes place to-night, and that in Cleveland is on Friday, March 17.

Chalmers February Shipments Total $3,000,000

DETROIT, March 12—During February the Chalmers Motor Co., shipped $3,000,000 worth of Chalmers. The biggest day was Feb. 29, when 193 cars were shipped. The number of orders carried over from February is 1747 and besides these there are now 4148 cars ordered for delivery in March. Indications are that April and May will be two record-breaking months for the company.

S. A. E. Discusses Gasoline

Metropolitan Section Expects Big Meeting—Dr. Rittman to Speak

NEW YORK CITY, March 14—At the meeting of the Metropolitan Section of the Society of Automobile Engineers to be held Thursday, March 16, at 8 p. m., at the Automobile Club of America, this city, the topic for discussion will be fuel. E. S. Foljambe, who has studied the subject for a number of years, is presenting a comprehensive paper on this topic.

Dr. Rittman of the U. S. Bureau of Mines, and W. A. Williams, chief petroleum technologist for the government have already signified their intention of being present, and a large attendance is expected in view of the pertinence of the subject.

Before the meeting there will be an informal dinner at which President Russell Huff of the S. A. E. and the council of the society will be the guests of the Metropolitan Section. The students from the neighboring universities have been invited, as have also members of the Motor Truck Club, Electric Vehicle Assn. and Automobile Dealers' Assn. The dinner will start at 6.30 p. m.

White for Detroit Section Chair

DETROIT, MICH., March 9—The annual election of officers of the Detroit Section of the Society of Automobile Engineers is scheduled for April 17. The nominating committee has prepared the following slate of officers for the coming administrative year: For section chairman, D. McCall White; vice-chairman, W. A. Brush; treasurer, J. G. Heaslet; secretary, B. G. Koether; for member of the national nominating committee, K. W. Zimmerschied; members of the nominating committee: S. B. Dusinberre, J. W. Stark and C. M. Hall, the latter as its chairman.

14,537 Licenses in Alabama

MONTGOMERY, ALA., March 10—The State board of equalization has issued 14,537 licenses to owners of automobile and motorcycles since the beginning of 1916. Of these, 11,615 were for pleasure cars and 2183 for motor trucks. There are many owners, however, who have failed to obtain new licenses and it is believed the total number of automobiles in the State is well up to 14,500. Jefferson County, of which Birmingham is the capitol, leads in number of machines with 2100 pleasure cars and 635 motor trucks. Montgomery County, in which is Montgomery, has 930 passenger machines and 160 commercial cars, while Mobile County has 912 pleasure cars and 192 of the other variety. One county is without a truck entirely, according to reports sent in, while the smallest number of machines in a single county is 20.

It is expected that the State will purchase very close to 5000 new cars during 1916. Financial improvement in both industrial and agricultural lines will bring this about. The war has brought prosperity to the Birmingham district, with its big steel mills, and enlargements and improvements have been coming rapidly. Other sections, with coal and iron interests, are feeling the improvement. The rural sections are benefitted by the clarification of the cotton situation and the improved condition of the market in the staple. Better methods of farming, likewise, are resulting in more profits for the farmers; road improvement and the establishment of national highways crossing the State are also factors in the growth of the automobile industry, and dealers in cars and accessories throughout the State are expecting a good year.

Half Total Rubber Used for Tires

Washington, D. C., March 13—The census bureau has issued a preliminary statement of the general results of the 1914 census of manufacturers with reference to the rubber industry. It shows, among other things, that the production of rubber tires for 1914 was valued at $146,411,692 and formed almost half, 48.8 per cent, of the total value of all kinds of rubber goods manufactured during the year. Statistics for the manufacture of tires were not obtained for 1909, but it may be safely assumed that the increase of 52.1 per cent in the total annual output of rubber goods during the 5-year period is accounted for in very large part by the enormous growth of this branch of the industry.

There was reported the manufacture of 8,020,815 automobile tires or casings, valued at $105,671,223; of 7,906,993 inner tubes, valued at $20,098,936; of solid tires for motor and other vehicles to the value of $13,735,681, and 3,728,138 motorcycle, bicycle and aeroplane tires, valued at $6,905,852.

Record Shipments in Feb.

21,502 Carloads of Automobiles Sent—Almost 100% Better than Feb. 1915

New York City, March 11—Record-breaking shipments of automobiles continued during February, when 21,502 carloads of automobiles were shipped. This is the biggest month in the history of the industry and almost 100 per cent better than February, 1915, when 11,973 carloads were shipped.

On account of the freight shortage, more than 1500 carloads were shipped on open cars covered with tarpaulins or in ordinary box cars by partly disassembling the automobiles, including the removal of mudguards.

It was expected that the larger part of 10,000 new railroad cars would be in service by this time to care for the increased production, but because of the inability of car builders to secure materials only 1200 of them have been put into service, making the total equipment of the railroads about 60,000 automobile cars.

Gramm Gets Big British Order

Lima, Ohio, March 9—The Gramm-Bernstein Co. has closed a $1,225,000 order for trucks said to be for commercial purposes in Great Britain.

Steel Prices Higher

New York City, March 14—Material prices continue to soar. With few exceptions prices are being maintained at the high level established during the past few weeks. Rubber seems to be the only product which is at the present time quoting around normal prices. The metals, however, are continuing on their skyward ascent. Both Bessemer and open-hearth steel prices are now double what they were before the start of the war. Aluminum and lead have taken another jump, and tin has established a new high mark by rising to $6 per 100 lb.

Though the price of gasoline remained constant last week a rise of significance occurred in crude oil from Kansas, which jumped to $1.45 a barrel with a net gain of 15 cents.

Last week aluminum rose 5 cents a lb., to 65, establishing a new high mark. Lead, which has been on the ascendency during the past month, again rose, reaching $6.85 per 100 lb. Bessemer steel, after a rise of $2 per ton the previous week, went up $3 more in price, establishing a record mark of $40. Open-hearth steel also rose to $40, the previous price being $38. Copper prices remained unchanged, the market being dull, with little business being done. The scarcity of tin has caused a further rise in quotations. This metal is now quoting at $55 per 100 lb. Though there is an active demand for spot tin, the scarcity of the product has been the cause for very little business being done.

Daily Market Reports for the Past Week

Material	Tues.	Wed.	Thur.	Fri.	Sat.	Mon.	Week's Ch'ge

Large Increase in N. J. Licenses

Newark, N. J., March 9—Registrations in New Jersey during the first two months have shown a large increase over the same period in 1915. To February 29, the collections of the Department of Motor Vehicles amounted to $726,633.26, as compared with $526,613.83 in the same period in 1915, an increase of over $200,000.

During this period the department has registered 56,012 cars, and 114 trailers. Drivers' licenses numbered 66,983; and transfers recorded were 862.

Australian Shipping Costs High

New York City, March 11—The American automobile manufacturer is now not only confronting a shipping problem by rail in this country, but one on his exports also. In line with his desire to open up trade in China, Australia and other countries, he must now pay the shipping companies high rates on account of few ships and lack of space. Just before the war rates to Australia were running from 25 to 30 cents a cubic foot. Now the shipping companies demand $1 per cubic foot. This means at this rate every one of the automobiles going to that country would cost for ocean freight alone approximately $400.

California Co. May Use Rittmann Process

Los Angeles, Cal., March 10—The first California company to apply to the government for permission to use the Rittmann process of refining gasoline is the Independent Oil Producers' Agency, of which L. P. St. Clair is the president. At present the agency members are producing large quantities of low gravity crude oil, which under the refining methods now employed yields very little gasoline. With the Rittmann process it is believed that a yield of motor spirits equivalent to gasoline, running as high as 60 per cent, may be obtained from the crude oil. The actual cost of producing the gasoline is estimated at 1 cent a gallon, exclusive of the cost of the oil from which it is extracted; and the officials of the Independent Agency confidently expect that they will be able to retail gasoline in California for less than 10 cents a gallon.

It is understood that the Rittmann process is to be held by the government solely for the benefit of the public, and that any improvements that may be made by companies which install the process eventually will become the property of the government. At the present time, however, refiners who make improvements will not be asked to share their secrets with their competitors, although all companies which adopt the process will be given the benefit of the knowledge now possessed by the federal officials.

The Independent Oil Producers' Agency will begin work at once upon their plant, and will soon be a competitor for the gasoline trade of California.

—

EAST PALESTINE, OHIO, March 9—The McGraw Tire and Rubber Co. has decreased its capital from $1,500,000 to $1,475,000.

—

CANTON, OHIO, March 9—The Timken-Detroit Axle Co. has increased its capital from $3,000,000 to $6,000,000.

—

ARVADA, COL., March 9—The Dry Climate Tire Mfg. Co., Arvada, has increased its capital stock from $200,000 to $500,000, and is arranging to install additional machinery in its new plant and increase its working force.

Mexican Affair Seems to Have No Effect on Quotations—Overland Rises to 228

NEW YORK CITY, March 12—Automobile and accessory security prices last week reversed the usual order of declines manifested during the year, and showed gratifying gains on top of a better market. The annual reports made by several of the companies listing their stocks on the Exchange probably were responsible for the upward tendency. The market is acting better than it has for months and there seems to be a persistent confidence in higher prices eventually. The new phase in the Mexican affairs serves to divert attention from our European negotiations. It is thought that the Mexican trouble will not be regarded as a particular menace to any market betterment.

Overland featured the market with a jump of 12 points, reaching 228, and 10-point rises were recorded by Chalmers, Miller Rubber and Paige. General Motors responded to the turn in prices with a 5-point rise, reaching 465. And Maxwell, Studebaker, Chevrolet, Goodrich, Firestone and U. S. Rubber came to the fore, after a period of declines, with very substantial gains. Chevrolet, especially, showed a gratifying gain of 7 points, after reports of its earnings during the past four and a half months had been reported.

Just what effect the present gasoline investigations will have on the stocks of the oil companies is not as yet known; however, oil stocks for the past two weeks have not been as strong as usual, both Texas and Vacuum issues showing drops during each of the two weeks.

Last week the New York Stock Exchange admitted to the regular list $3,758,200 6-per cent cumulative preferred stock and $3,582,500 common stock of the Kelly-Springfield Tire Co. This company may also add $1,324,700 in common stock on official notice of issuance, making the total amount of common to be listed $4,907,200.

General Motors featured the Detroit Exchange with a rise of 37 points, reaching 462½. Prices in that city showed a higher tendency. Chalmers common rose to 152 at a gain of 13 points.

During February 80,580 shares of stocks were sold on the Detroit Exchange, not including 296 shares of stocks of banks. The biggest sales were those of Reo Motor Car Co. shares, the total which changed hands being 22,400, at from 33⅞ to 39¼ per share. Of the now Continental Motor Co.'s shares at $10, a total of 12,379 were sold, at from 25 to 35¼, while of the old stock at $100, 1085 changed hands at from 292 to 515 a share.

—

Dividends Declared

Electric Storage Battery Co.; 1 per cent from net earnings of company on common and preferred, payable April 1 to stock of record on March 21.

Willys-Overland Co.; quarterly of 1¾ per cent on preferred, payable April 1 to stock of record March 21.

Chandler Motor Co.: quarterly of 1½ per cent, payable April 1 to stock of record March 7.

Factory Miscellany

Armstrong Spring Co. to Enlarge—An addition, 60 by 260 ft., is to be put up at the plant of the J. R. Armstrong Mfg. Co., Flint, Mich., automobile spring manufacturer.

Continental Motor to Add—The Continental Motor Co., Muskegon, Mich., has been granted permission by the city for the erection of new steel and concrete machine shops, which will be additions to the present sawtooth buildings on Western Avenue and Water Street. Plans have also been made for the erection of a new sand blast.

Jones Motor Co. Buys Plant—The Jones Motor Car Co., Wichita, Kan., has purchased the plant formerly occupied by the Burton Car Works in the North End, Kansas City, Mo., and will move the Jones car factory there as soon as the necessary improvements can be made.

Hayes Truck Adds—The Hayes Motor Truck Wheel Co., St. Johns, Mich., recently installed a new band saw and is now sawing its own logs. Heretofore the company had been using rough planks bought from lumber companies, which now is no longer necessary.

Atlas Drop Forge Completes Addition—The Atlas Drop Forge Co., Lansing, Mich., has completed an addition 40 by 150 ft, for the heat-treating department; also a 70-ft. addition to the steel shed. Foundations are being laid for six new mammoth hammers.

To Make Hubs for Four-Wheel-Drive Cars—E. C. Heimke of the Northern Machine Works, Wausau, Wis., is preparing to undertake a production of a new type of hub for automobiles and trucks with four-wheel drive. Mr. Heimke has been granted patents on the device. He also is the inventor of a portable stone picker, in the form of a light trailer to be attached to vehicles. The picker rakes up and gathers all stones, sticks and other obstructions on highways. The rubbish is conveyed from the road surface into a container.

Hall Secures New Building—The Hall Motor Co. has secured a building at Markham, Ont., and will install equipment for the manufacture of trucks, engines, etc.

New Haven Carriage Adds—The New Haven Carriage Co., New Haven, Conn., builder of automobile bodies, has begun the construction of an addition, 50 by 90 ft., two stories.

Belknap Remodeling Plant—The Belknap Wagon Co., Grand Rapids, Mich., is remodeling its plant and will add to its equipment machinery suitable for the manufacture of automobile bodies.

Buick Adds—The Buick Motor Co., Flint, Mich., is taking bids on the erection of a new heat-treating plant to cost about $9,000.

Truck Plant in Milford—The F. W. Mann Co., Milford, Mass., has bought a one-story building on Central Street and will increase its capacity. This company manufactures trucks.

Hartford Parts Not to Move—The Hartford Automobile Parts Co., Hartford, Conn., has decided not to move to New Britain, as planned, but will retain the old Cheney mill property and operate the New Britain works as a branch. The company plans to increase its capital from $300,000 to $600,000.

Marshall Co. Makes Parts—The Marshall Castings Co., Marshall, Mich., which was organized only a few weeks ago, will specialize in automobile parts. The two first orders which the company has received are from the Buick Motor Co., Flint, and from Dodge Bros., Detroit, and are of a total value estimated at $20,000.

Oct. 19	Indianapolis, Ind., Race, Indianapolis Motor Speedway.

The Week in the Industry

McFadden Buffalo Firestone Mgr.—H. W. McFadden has succeeded A. L. Manley as manager of the Buffalo branch of the Firestone Tire & Rubber Co. Mr. McFadden was transferred from Dallas, Tex.

—

Dealer

Southwest News Items—The Hannon Motor Sales Co., Tulsa, Okla., agent for the Oakland in four of the State's largest counties, has opened a branch salesroom at 616 Okmulgee Avenue, Muskogee.

M. S. Pogue, formerly of San Antonio, Tex., has been named general manager of the Muskogee Overland Co., agent at Muskogee, Okla., for the Overland.

D. D. Davis, Kansas City, Mo., has opened a salesroom at 1922 Grand Avenue, and handles the Scripps-Booth cars in the Kansas City territory.

The Western Auto Supply Co., Tulsa, Okla., has absorbed the Segar Auto Supply Co.

The Joplin Motor Co., Joplin, Mo., has moved into new quarters at 517-520 Joplin Street. The company is distributor for the Studebaker line in six southwestern Missouri counties and two adjoining in Kansas and Oklahoma. A trainload of eighty cars will be received by the company about March 15.

The Chase Motor Truck Co. of Missouri, Kansas City, Mo., has been organized to look after the distribution of the Chase line of trucks in Kansas City. William Wallace is head of the new company and service quarters have been opened at 413-415 Wyandotte Street.

Packard to Build in Pittsburgh—The Packard Motor Car Co., Detroit, has awarded the contract for the construction of a two-story, 100 by 233 ft. service building at Pittsburgh, Pa. The estimated cost is $200,000.

Salt Lake Co. Branches Out—C. L. Evans and A. M. Daly have bought the India Rubber Mfg. Co., 336 South State Street, Salt Lake City, Utah. In the past the company has very largely confined itself to the operation of a vulcanizing plant. The new owners intend to add automobile tires and supplies.

Rex Ignition's New Branch Offices—The Rex Ignition Mfg. Co. has established branch sales offices in Philadelphia and Chicago. F. E. Bruckner is manager of the Chicago branch and William Payne, formerly with the Ferguson Publishing Co., takes charge of the Philadelphia office.

Motor Men in New Roles

Bradner Auto Body V.-P.—H. E. Bradner, since the organization of the Auto Body Co., Lansing, Mich., secretary and general manager of the concern, was, upon his request, relieved of the office of secretary and elected vice-president. He will continue as general manager. As secretary of the company the directors have chosen F. C. Ruch, a stockholder and a well-known insurance man.

Tobin Promoted by Willard—F. D. Tobin, who has been connected with the branch of the Willard Storage Battery Co. in Detroit, has been promoted to assistant district manager of the Detroit territory.

Rippingille Hudson Assistant Mgr.—E. V. Rippingille has been appointed assistant sales manager in charge of service by the Hudson Motor Car Co., Detroit. He has been with the company since its inception.

Greiner Jeffery Secretary—G. W. Greiner, formerly in charge of the credit department of C. T. Jeffery Co., Kenosha, Wis., has been made secretary of that concern.

De Vault Promoted—A. L. De Vault, who was manager of the Detroit branch of the Federal Rubber Co., has been promoted and now has charge of the central district, which comprises the territory of the Detroit, Cleveland, St. Louis and Chicago branches, which have been combined and are now placed under the direct jurisdiction of the Chicago headquarters.

Bloom Rex Sales Mgr.—L. S. Bloom, for years British sales manager of the Rex Ignition Co., has been appointed sales manager of this company in the United States and Canada. Mr. Bloom assumed his new responsibility on March 1, making his headquarters the New York office of this concern.

Whisler Peru Parts Super.—I. S. Whisler has been promoted to the position of superintendent of the Peru Auto Parts Mfg. Co., Peru, Ind.

Williams Chicago Goodyear Mgr.—C. H. Williams has been made manager of the Chicago branch of the Goodyear Tire & Rubber Co., with headquarters at 1601 Michigan Avenue. He was formerly manager of the branch in Portland, Ore.

Duffield with U. S. Rubber—J. E. Duffield has joined the U. S. Rubber Co. interests by becoming sales manager for the Mechanical Rubber Co., Chicago.

De Land with Milwaukee Chalmers—L. S. De Land has been appointed sales representative of Harry Newman, Inc., Milwaukee, distributor of the Chalmers car.

Hoover Leaves Splitdorf—C. A. Hoover has resigned his position with the Splitdorf Electrical Co. to take a Western agency for the Rex Ignition Mfg. Co. He will be located at Kansas City, Mo.

—

Dealer

Philadelphia News Item—The branch of the Goodyear Tire & Rubber Co., 207 North Broad Street, Philadelphia, Pa., has increased its business to such an extent that additional quarters have been added at Twenty-fourth and Locust Streets. The new warehouse contains 23,180 ft. of floor space and will accommodate 25,000 tires.

Philadelphia contractors are estimating on the erection of a factory addition to the plant of the Hess-Bright Mfg. Co., maker of ball bearings, at Front Street and Erie Avenue.

The Baker-Price Co., which has handled the KisselKar in this city for some time, has been made sole distributor in this territory for the Westcott.

The interests of F. Winsor Eveland in the Yerkes-Eveland Co., distributor of the Stearns-Knight, have been purchased by President William Yerkes. The latter has plans under consideration for improving the business at 1411-1419 Spring Garden Street.

The Reading-Philadelphia Auto Messenger Co. of Reading has been formed with S. H. Hochfeld as manager. The company, practically the first of its kind in the field, will operate several auto trucks between Reading and Philadelphia.

Opens N. Y. Office—The United Smelting & Aluminum Co., New Haven, Conn., has opened a branch sales office in New York City at 26 Stone Street.

New Supply House in Newark—The Elin Auto Supply Co., 273-275 Halsey Street, Newark, N. J., has just started business. Edward Elin is manager.

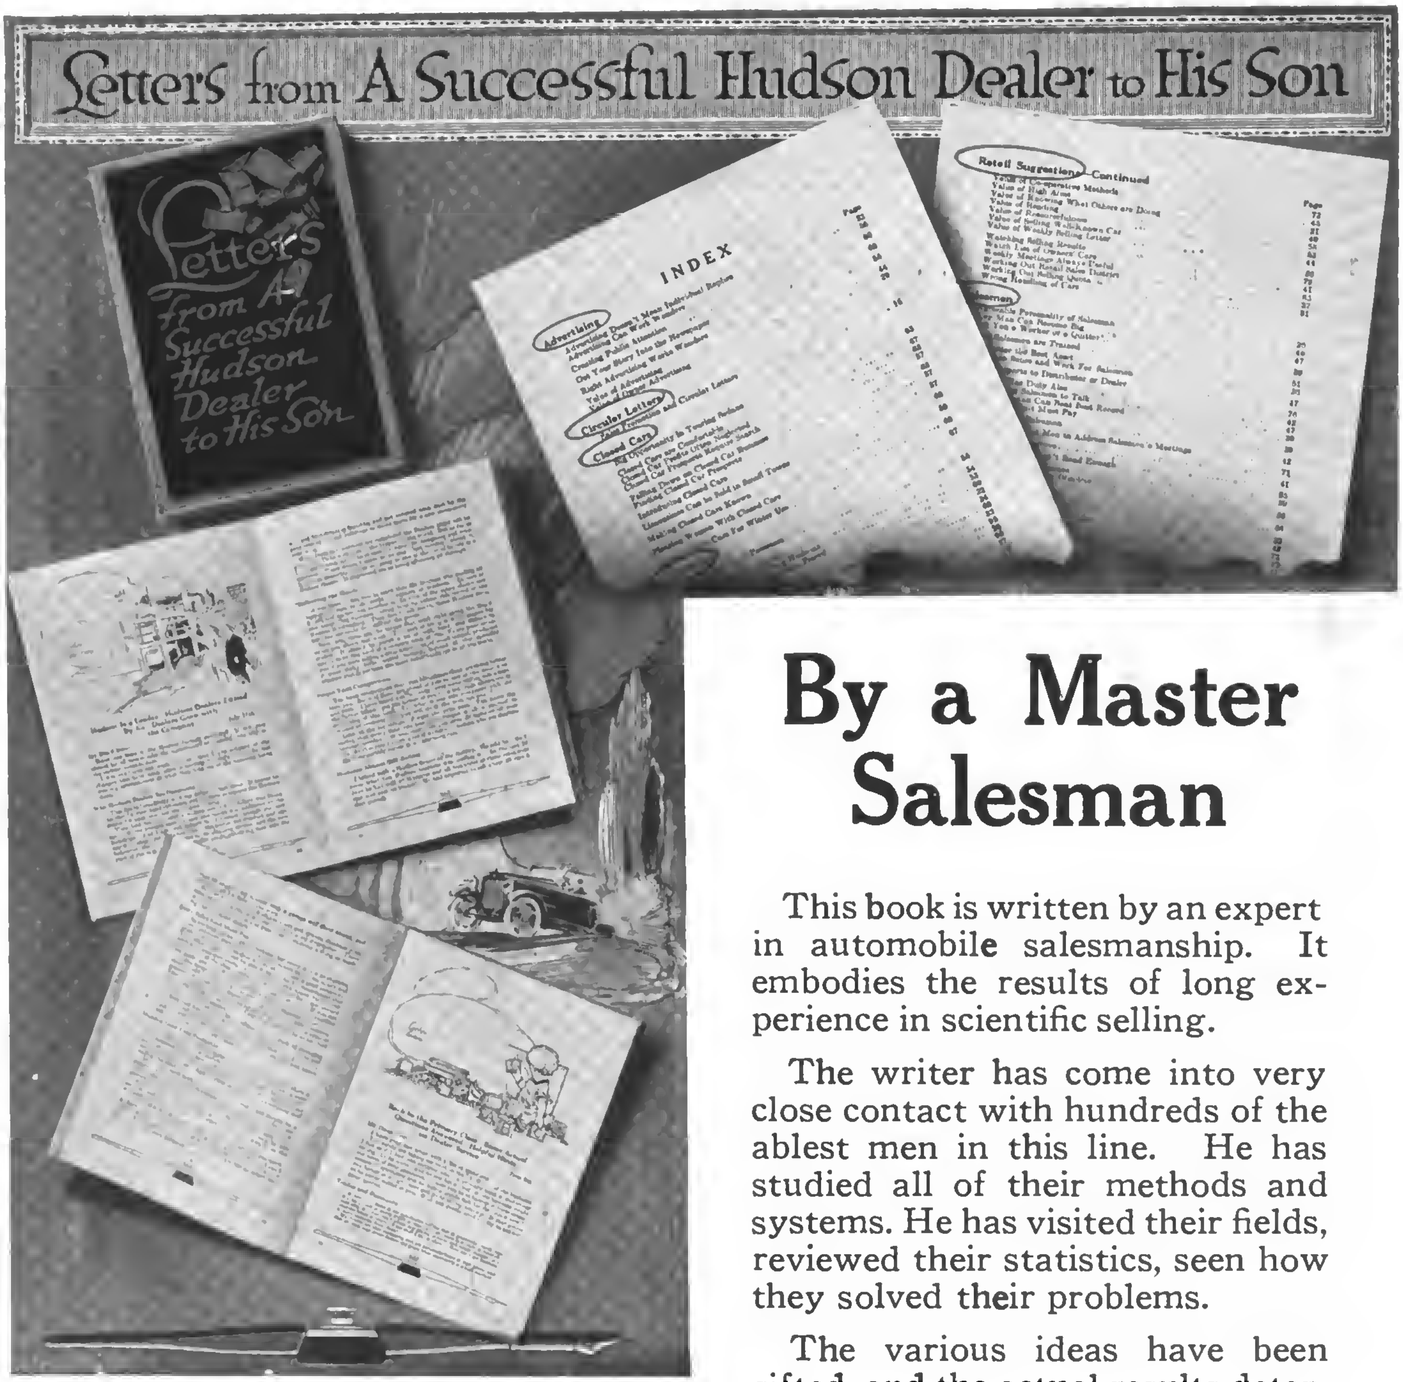
U. S. L. Offices Moved—The New England office and service station of the U. S. Light & Heat Corp. have been moved to the Exposition Bldg., Cambridge, Mass., from 25 Irvington Street, Boston. The Detroit office has recently moved from 203 Monroe Avenue to 43-45 Brady Street.

The AUTOMOBILE

Vol. XXXIV,
No. 12

NEW YORK, MARCH 23, 1916

Ten cents a copy
Three dollars a year



By a Master Salesman

This book is written by an expert in automobile salesmanship. It embodies the results of long experience in scientific selling.

The writer has come into very close contact with hundreds of the ablest men in this line. He has studied all of their methods and systems. He has visited their fields, reviewed their statistics, seen how they solved their problems.

The various ideas have been sifted, and the actual results determined. So the countless suggestions made in this book are the best that the line has developed. Not a man in this line can read this book without becoming a better salesman. And many a man can multiply his earning power by studying these suggestions.

Send 25 Cents and this book will be mailed you. It was written, of course, for Hudson salesmen and dealers. But its principles of salesmanship apply to every make of car. Also its ideas on territory, on computing possibilities, on service, on used cars, on all the problems which confront a worker in this line. The Hudson Company is very glad to share them. Send us 25 cents as evidence of interest. If you do not think the book is worth it, the amount will be returned. Mail us the coupon now.

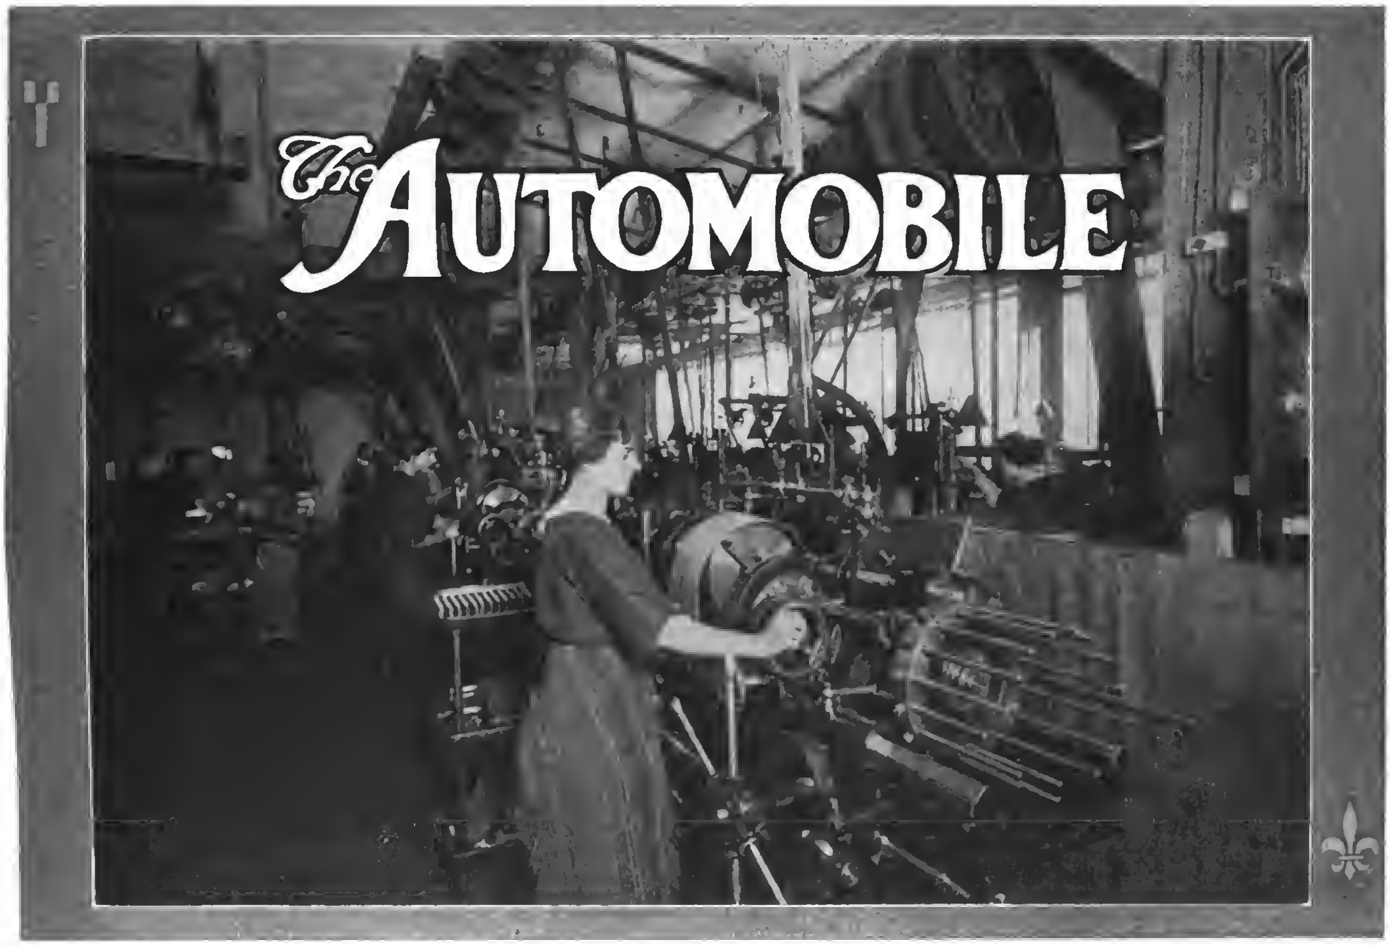
The AUTOMOBILE



Women in Europe are finding machine shop work both patriotic and profitable

British Industry Better Equipped

Effect of War Different in Different Plants—Reorganization for Munition Making Will Aid Better Manufacturing in Peace Time—Cheaper British Cars Anticipated

ASKED how the British automobile industry stood at the present time, one of the leading manufacturers replied "There isn't any British motor industry now—that's all there is to say." It was the same maker who, asked by King George, during an official visit, how the war had affected them, replied "It has given us Hell."

In the same town, not more than a mile away, another automobile manufacturer said "come and see." And he took me through shops with not a square inch of waste space in them; he showed me women and girls making hand grenades and encouraged to maximum output by means of intelligently distributed premiums; he took a pride in pointing out a score of contrivances to simplify operations and adapt existing machinery to special munition work; he showed how, by an intelligent system, he was able to secure material and was able to keep his car section running on a reduced scale while making bigger deliveries of war material than the army had estimated his factory could produce.

Another manufacturer's leading hope was that the government would prohibit the importation of automobiles for two years after the war. A fourth was of the opinion that if England could not compete with foreign nations without protection there was something wrong with her system. He also pointed out that the American car, by coming in when the British manufacturers were unable to supply, had saved hundreds of automobile dealers from financial disaster.

These examples have been given to show the varied viewpoints of the British automobile manufacturers. Go into one factory and there is dark pessimism; go into another and it is to find buoyant optimism; in a third the outstanding feature is jealousy that a rival should have found means to keep on with a certain measure of car production; another has grasped the truth that it is necessary, first and foremost, to get through with the war, and let the future take care of itself. There is no uniformity of view; there are no indications of any national program for the future conduct of the automobile industry; there appears to be very little hope that the government will assist the industry in the critical reconstruction period which will immediately follow the war; it does not seem that any plan has been worked out by which the government could help the industry. The general impression gained after mixing with members of the English automobile industry is that the British car manufacturer does not realize his own strength. He has accepted war conditions according to his particular temperament; he is going through to the end, whatever the end may be; but he has not yet had time or sufficient imagination to lay out possible plans.

All Factories State Controlled

Practically the whole of the English automobile factories are state controlled establishments. The exceptions are some of the smaller factories which, while undertaking a ceramount of military work, are also continuing the production of cars or other components in which they are normally interested. The amount of such work being done for private owners bears a very small porportion to the whole, and is not worth the indignation, or jealousy, as the case may be, of those manufacturers who have been absorbed entirely by the war machine. In this connection, there is no ground for a suspicion that some English makers appear to have, which is that the French factories are doing more private business than they. The English are doing little for the civilian client; the French are doing less.

Conditions Vary Widely

Factories under government control are not necessarily prevented from making automobiles; but they are prevented from doing other than government work, except under special circumstances and with special permission. There are shops in which hardly a shell is to be seen, the entire plant and all hands being employed on trucks, touring cars and aviation motors for the army. In others not a single machine is running on automobile parts. The former have a certain advantage over the latter, for they are keeping their staffs on the usual work, they are gaining experience with war models, and that experience can be put to good use when peace conditions are re-established. It appears to be one of the chances of war whether a factory shall be kept on trucks and cars or on shells.

The fact is obvious, merely from an examination of the English automobile factories, that there has not been the single national control of the industry which is such a distinctive feature of the continental industry. A few of the big factories were switched from civilian car work to the production of military automobiles within a week of the outbreak of war and have from that time to the present date been employed exclusively and ever-increasingly on war material. Other and smaller manufacturers state that for months they tried to get war contracts for either automobiles or munitions and failed to obtain any satisfaction from the authorities. Finally they were able to get sub-contracts from the big contractors.

Half-Finished Cars

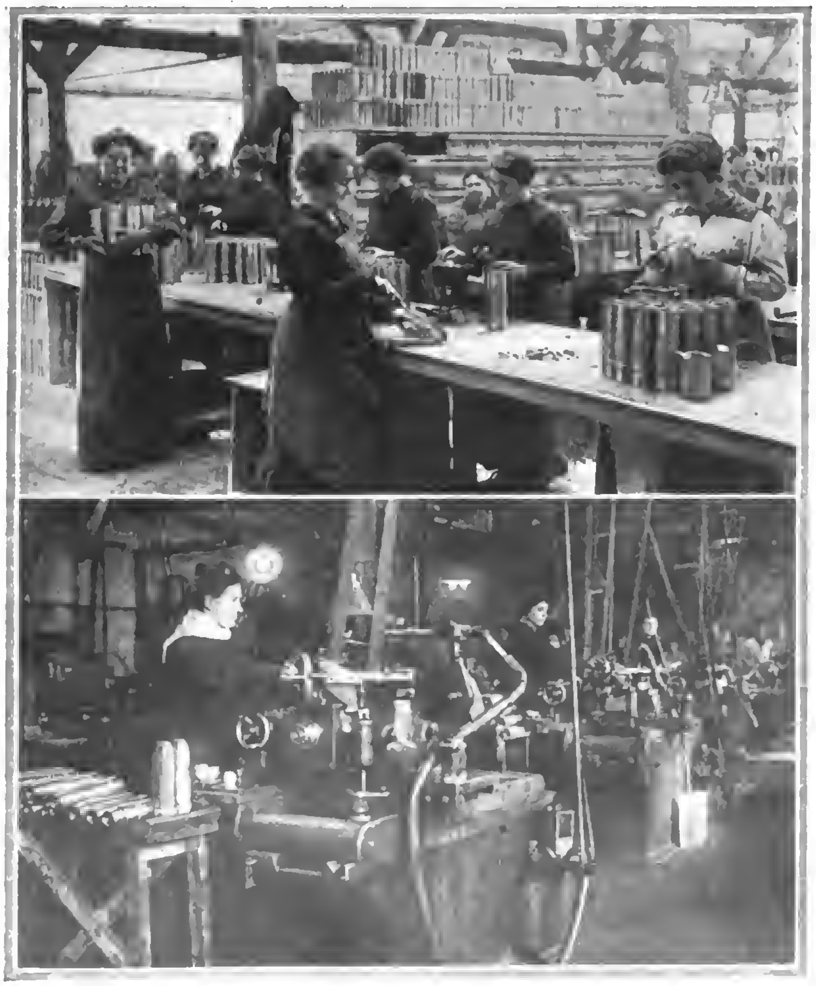
Many of these factories now running two shifts on war munitions were doing practically nothing when Asquith made his famous "no shell shortage" speech. Other cases are to be found where factories tried to carry on their ordinary production, building for stock under the impression that the war would be short and that there would be a big demand for cars at its close. Several of such factories were suddenly ordered to accept contracts for shells and other military material, and work on cars had to be stopped at practically a moment's notice. This is shown by the large stocks of partly finished material—frames, cylinders, gearboxes, axles, motor units, etc.,—sometimes piled up nearly as high as the roof. Control is so close that even the little labor necessary to transform some of these units into complete cars cannot be obtained.

In these shops it will be an easy matter to resume work on automobiles without loss of time as soon as military restrictions are withdrawn. Obviously however, the pre-war models will have to be continued for a certain length of time.

Engineering Activity at Maximum

Although there is still room for extension in some of the automobile factories, the engineering industry as a whole appears to be getting very near its maximum output. One authority states that the limiting factor now is the world's production of steel. He claims that the amount of steel used for shell making at the present time is equal to the total world's output before the war. As an instance of the world-wide influence of the war on the metal industry, Japan is now supplying some English factories with brass bars.

The work done during the past twelve months is nothing less than stupendous. In this connection it is necessary to avoid anything like precise statements, for obvious reasons. As instances of activity, I was shown one factory employing 2500 Belgians—men and women—running two shifts and working six and one-half days a week, producing 3500 shells a day, having six hydraulic presses which would go into service within a week and increase the output 100 per cent, and possessing a laboratory and test department equal to those of the best engineering establishments to be found in any part of the world. Where this modern, highly efficient, and well organized factory now stands, there was but one year before an uncultivated field without a brick on it. It was not only necessary to plan, build, and equip that factory,



Making and loading shell in a factory where high grade passenger cars are the stock product

Frenchwoman operating a lathe in the Panhard factory in Paris

Girls gauging shell parts in the Panhard plant

but to bring together and find accommodation for the workpeople and their families, numbering about 4000 people, most of whom did not speak a word of English.

In another town a French automobile company had opened an English factory and had trained 300 mechanics to the highest class of work in which no tolerance whatsoever is allowed. All finished parts have to be dead accurate. While this work is going on in the temporary factory, a bigger factory for 1000 workpeople is being erected, the builders being under a penalty of $500 per day for late delivery. In addition to this factory, the same company has completed a new factory in the south of France and has doubled the size of its original factory. Practically all the automobile factories of the Midlands are extending, building operations going on both day and night by the aid of special electric lights.

Women Do Good Work

Increased output has only been made possible by a considerable dilution of skilled labor and the introduction of women on work to which they were originally entire strangers. This change is less evident in the automobile than in the national ammunition factories. Nevertheless women are now an important factor even in the automobile shops and they have been responsible for a considerable amount of speeding-up. It is found an easy matter to train a woman to get the maximum out of a machine, and this has had its influence on men who have systematically kept machines below their maximum output.

The change in the internal organization of the factories has not been possible without some friction. There have been strikes in certain districts, and there are a few labor disturbances at the present moment. But so far as the British automobile industry is concerned, it has not been found possible to discover a single case of a strike, and where there have been dissensions they have always been settled amicably by a straight talk between employers and workpeople.

As an indication of the spirit of the workpeople in the automobile industry, one man in a factory of 2000 workers refused to join up under the Derby recruiting scheme. He was roped into a wheelbarrow and taken by force through the streets of Coventry to the recruiting station. In another factory in the same town 500 men threatened to down tools if a Colonial, who had refused to recognize the recruiting scheme, was not dismissed. The man was obliged to leave without waiting for a dismissal from the firm, and could not gain employement elsewhere in the town.

Joining the army under the group scheme does not make any material change to the majority of the men in the automobile factories, for they are in reserved occupations and are considerably more use to the army as mechanics than as soldiers. The fact remains, however, that by joining the groups they put themselves under military law and could be drawn from their present occupations and put into the army if it became necessary to do so for any reason. The manner in which Briand stopped the railroad strike in France a few years ago by putting the strikers under military law is an example of the force of this weapon.

Wages Are Raised

There has been a general increase in wages, but this has not attained the proportions stated in many quarters. From close inquiries it is found that wages in the automobile industry have risen 25 per cent on an average. At the same time food prices have increased 30 per cent. As this increase does not apply to more than one-half of the worker's necessary expenditure, the net result is to his advantage. Stories of youths earning $25 to $30 a week are nearly always found to be based on some special week when accumulated bonuses were paid. In some of the automobile body-building factories expert workers on piece rates are drawing $25 a week for aeroplane propeller construction, but this is above the average even in this particular branch. The general condition of working families in the automobile trade is better than at any previous time, for whereas before the war only one member worked, now three to four members can find employment with a minimum wage of $5 a week for girls.

Experimental Work Progresses

Although very little publicity is given to the fact, experimental work is still being carired on to a limited extent, in the best English factories. In addition, the best arrangements possible are being made to return to the usual class of work as soon as release is obtained from army contracts. On the whole the English factories are better placed in this respect than are the French. In England production was stopped suddenly and no attempt made to use up the series in course of construction. In France manufacturers gradually exhausted their stocks and only ceased building cars when they had nothing more to build them with.

Not much information is allowed to get out regarding the contemplated after-the-war models. It is certain, however, that there will be a decided increase in the number of medium priced cars and in small light two-seaters with four-cylinder motors 60 by 110 to 70 by 140 mm. bore and stroke. It is believed that whatever the outcome of the war strict economy will be exercised for a number of years and that there will be no demand for big cars which will be costly to maintain on account of high taxation, high cost of fuel and tires. At the present time there are important factories with a reputation for the best work and an experience in big cars only, now decided on the production of big series of 10 hp. two-seaters. These are four-cylinder models with a cylinder bore of 70 mm. maximum. Other firms, hitherto connected with a couple of models, one of them of 10 and the other of 14-16 hp., have decided to drop the bigger type and devote themselves after the war to the 10-hp. type.

No Expensive Cars Wanted

The position of firms producing costly models only is not looked upon as particularly bright for the period immediately after the war. It is known, indeed, that one of these firms is contemplating the construction of automobile trucks, a class of work to which it has never previously paid any attention. At the end of the war several thousand big cars, varying from 16 to 30 hp. will be turned on the second-hand market, and these are bound to have a disturbing influence on the higher class of car trade. A few twin sixes are under consideration, but it is rather significant that the only firm which is at present certain to produce a twelve-cylinder car is making arrangements for the bulk of its output to be 10 hp. 2 and 4-seated light cars. Considerable experience in twin sixes is being gained on aviation work, with the possibility of some really good automobile motors with this number of cylinders.

Whether prices will be cut after the war depends largely on the cost of raw material. Assuming that material can be obtained at the same price as previous to the war, prices will certainly drop, better organization, more modern plants and a general speeding up all tending to make this possible. Several instances could be given of new factories built exclusively for war orders, which will show a profit and have the initial cost of the plant completely wiped out if the war comes to a close a year from this date.

Magneto Business Problematical

The British motor industry never has had to face important competition from Germany and is likely to have less after the war. Public opinion is alone quite sufficient to prevent the sale in England or her colonies of the leading German cars. The situation is not the same with regard to magnetos. In 1913 Great Britain imported magnetos to the value of $100,000, and of this amount Germany was responsible for $95,000. Austria sent practically none, the small remaining surplus coming from France. Since then conditions have changed, all the imported magnetos coming from America. A few of the English electrical firms have taken up magneto construction, the most important development being the Thompson-Bennett Co., Birmingham, which is an auxiliary of the powerful Lucas company. There is a hesitancy about putting money into the magneto business until definite guarantees are given of a protective tariff for a minimum number of years. The Government Commission appointed to inquire into this question has proposed a 33 1/3 per cent duty on all foreign-made magnetos. If this is adopted, and there is little reason why it should not be put into effect, there are no indications in England or anywhere in Europe, that the use of the magneto will be lessened by reason of the present situation. Electric lighting and starting will be found on all European after-the-war models, but this is not likely to supplant the separate magneto for ignition purposes.

Eight Firms Make Aero Engines

The bulk of the aeroplane motor construction is in the hands of eight automobile firms, of which five are building V-motors and the three others various types including V's. Although every type of motor is in use, including Gnomes, eight-cylinder air-cooled, eight-cylinder water-cooled, six-cylinder vertical water-cooled, and twelve-cylinder water-cooled, the tendency is towards the V water-cooled motor with eight or twelve cylinders. Power is increasing, the opinion holding that comparatively few motors will be produced of less than 200 hp.

For hydro-aeroplane work numbers of twelve-cylinder motors developing 300 hp. and more are being produced. The most important of these is a twelve-cylinder of 100 by 160 mm. bore and stroke. This change from 75 to 80 hp. motors running at 1200 r.p.m. to motors of 100, 150, 200, and even more than 300 hp., running at 2000 r.p.m., and having a geared-down propeller, is one of the most important developments in connection with the automobile industry.

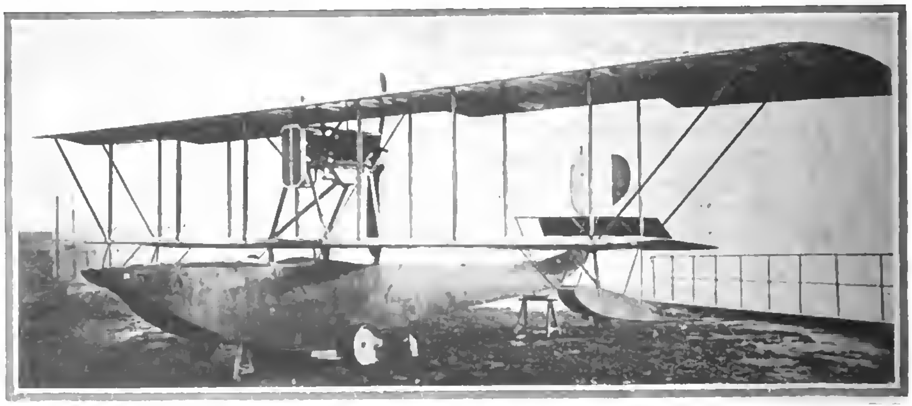
This movement is not confined to the British, but is general throughout the Allied countries. In France, Peugeot and other factories working in conjunction with them are producing thousands of eight-cylinder V-motors, the direct outcome of racing practice. In England the twelve-cylinder Sunbeams for aviation work have only been made possible by reason of racing experience.

While there is very little use of aluminum alloy pistons to be found on the Continent, the leading English firm uses aluminum-alloy exclusively. It is understood that this firm has spent $10,000 on experiments and has produced an aluminum nickel alloy piston which is perfect and can be used with the same clearances as an all-steel piston.

Hispano-Suiza Aluminum Engine

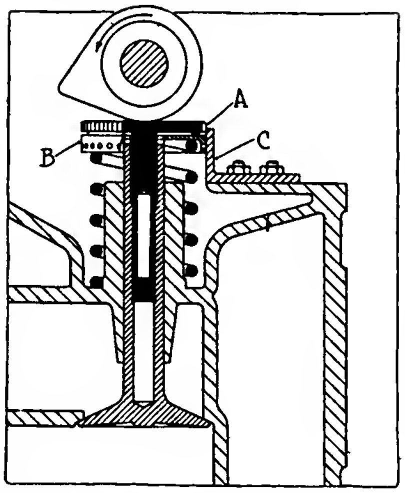
The aviation motor which is attracting the greatest amount of attention is the eight-cylinder Hispano-Suiza now being built in England. This motor is probably the first aluminum cylinder engine to be built in any quantities. It was first produced more than a year ago at the Barcelona factory of the Hispano-Siuza company and brought before the French authorities, who have decided to adopt it and had it built in the main factory of this company at Paris. It has since been taken up under license by other firms in France and more recently has been secured by the British government.

This motor has its cylinders cast in groups of four with steel liners inserted. A detachable cast-iron head carries the valves—two per cylinder—and the overhead camshaft is driven by bevel gearing and a vertical shaft at the front end of the motor. One of the patented features of this motor



An Hispano-Suiza hydro-aeroplane which has an eight cylinder aluminum engine with a special valve mechanism is the direct operation of the cams on the valve stems, without any intermediate mechanism. The general principle is shown in the illustration. There is a separate carbureter for each group of cylinders and lubrication is under high pressure to all parts, with the oil passing through a radiator.

The valve stem is hollow and has an adjustable tappet screwed into its open end. The upper end of the tappet rod carries a disc which is slotted on its edge and formed with teeth on its under side. Beneath this disc there is a second disc which is threaded on to the tappet rod, so that the rod can turn in it, but this second disc is keyed on to the valve spindle by two lugs formed on the end of the spindle. The second disc also has teeth formed on its upper face to engage the teeth on the first disc, and the two are held in engagement by a spring.



Details of the valve tappet adjustment used on the Hispano-Suizer aluminum aeroplane engine. It gives quick adjustment and is light in weight

Adjustment is effected by screwing the tappet rod up or down in the valve spindle, and it is locked once it has been adjusted by the inter-engaging teeth on the two discs, for the lower disc cannot rotate relatively to the valve spindle. The adjustment is effected by a double toothed wrench, one tooth being engaged with circumferential holes in the lower disc and the other tooth being engaged with the slots in the edge of the upper disc so that turning one of the wrenches causes a slight relative movement of the discs.

This motor drives the propeller through spur reducing gears. With a bore and stroke of 4¾ by 5⅛ in. the motor weighs 363 lb. when equipped with two magnetos and a duplex carbureter. Cooling water is not included in this weight. Fuel consumption is 11 gal. of gasoline and 1 gal. of oil per hour. Horsepower is 200.

Official aeroplane motor tests are now very severe. The French authorities demand 50 hours' constant running, half of this at three-quarter power and half at full power. The British put all motors through a 100 hours' test before accepting and in the case of big units make them run at the end of 100 hours with the propeller out of balance for a short time.

Rushing Trucks to Mexico

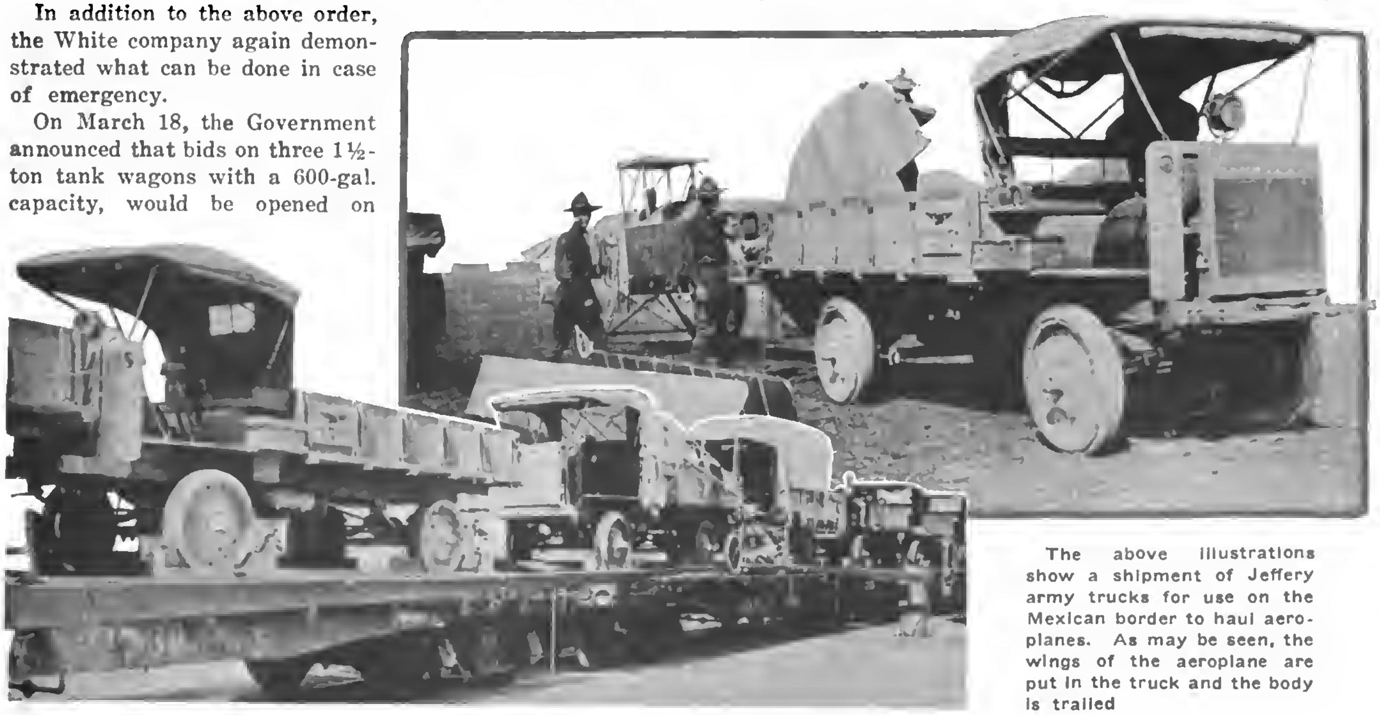
THE speed with which American truck companies can be mobilized to supply the sudden needs of the United States army was demonstrated this week when a long distance call from the War Department to the White Co. resulted in the dispatching of a special trainload of White army escort trucks to the Mexican border within 24 hr. after the order was placed.

Bids were opened at 10 o'clock on Tuesday morning and by 5.30 that afternoon the order was sent to the factory for twenty-seven chassis and one truck, which left 6 o'clock Wednesday morning. On Thursday morning the bodies and parts for these trucks were shipped, and that evening the entire personnel of White Truck Co. No. 1, consisting of one truck master, three assistant truck masters, twenty-eight chauffeurs, one mechanic and a helper, left for the Mexican border.

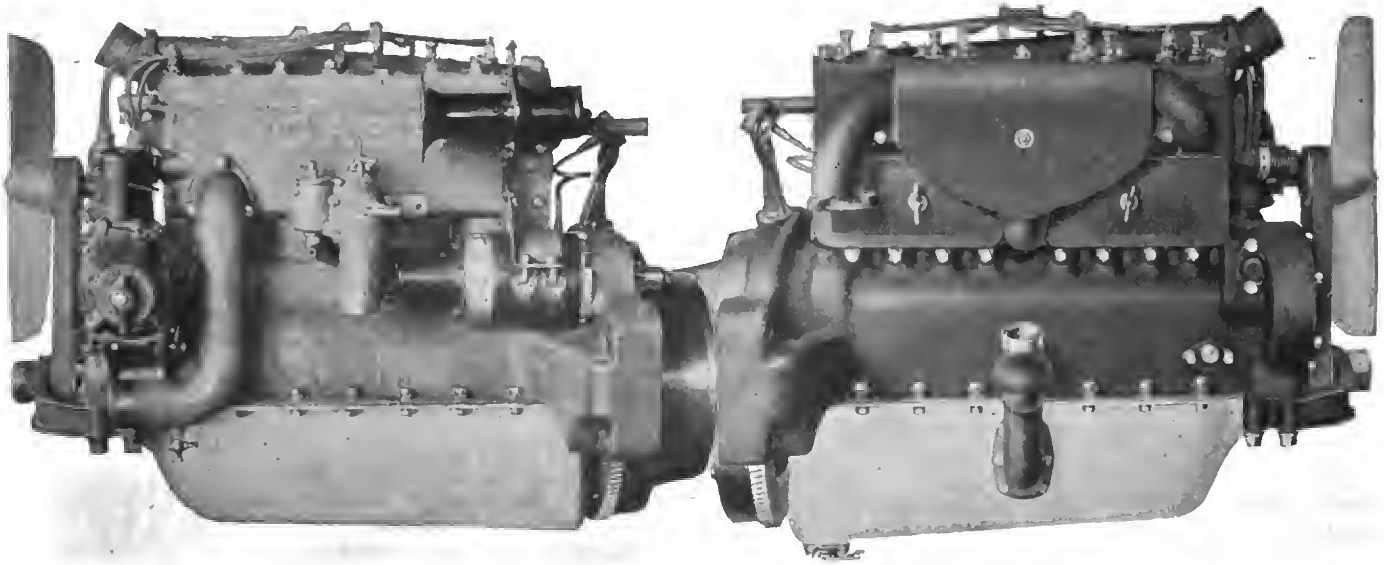
In addition to the above order, the White company again demonstrated what can be done in case of emergency.

On March 18, the Government announced that bids on three 1½-ton tank wagons with a 600-gal. capacity, would be opened on March 20. In between those two days, the White company found out that the Standard Oil Co. of New York had recently installed three of these tanks on White trucks, and immediately got into communication with them. As the Standard Oil Co. was willing to help out, the War Department was told that immediate delivery could be made on the order, which was accepted.

The Thomas B. Jeffery Co., which also figured prominently in the War Department order for twenty-seven trucks, received its order at 5 o'clock Tuesday night, March 16. At that time the workmen in the factory were leaving for home, but the Jeffery officials called them back, the order being rushed through that night. The trucks were in the freight cars at 7 o'clock Wednesday evening. The full equipment of thirty-three men was on the train at 2 a. m. Thursday.



The above illustrations show a shipment of Jeffery army trucks for use on the Mexican border to haul aeroplanes. As may be seen, the wings of the aeroplane are put in the truck and the body is trailed



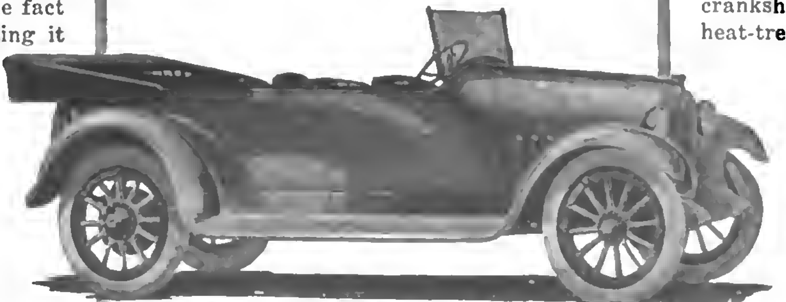
Accessibility Features Case Forty

Compact Power Plant Gives 40 Hp. at 2100 r.p.m.—Uses Detachable Cylinder Head, Integral Crankcase and Unit Construction—Test Shows Easy Suspension and Flexibility

DESIGNED especially to appeal to those who believe in a four-cylinder car, the Case Forty has been put out with the idea of incorporating the essentials of careful workmanship necessary to make this vehicle compete with the lower priced sixes. Selling at $1,090 the Case Forty, as will be noted, is in a price field which is almost as thickly populated by six and more cylinder cars as it is by fours, and consequently in a study of the design it will be seen that the flexibility and power demanded at this price have been attained in the four-cylinder motor. Throughout the design is of a rugged character.

The car itself is large and roomy, having capacity for seven passengers and a wheelbase of 120 in. A test of its riding qualities shows it to be exceptionally well sprung and also to be capable of the speed demands of practically any tourist. On intermediate gear the motor propelled the car at 32 m.p.h. without any troublesome vibration and on high gear a speed of over 60 m.p.h. should readily be attained, although on the test run this was not done by THE AUTOMOBILE representative owing to traffic laws and the fact that the car was new making it undesirable to operate at the highest speed.

Brake horsepower between 40 and 45
Detachable L-head block cast motor
Silent chain camshaft is adjustable
Magnetic pinion starter engagement
Pedal compensates for clutch wear



The new Case Forty

The manufacturers rate the engine as having from 40 to 45 brake horsepower at a speed of 2100 r.p.m. The four cylinders are cast in a single block and have 3⅝ bore by 6-in. stroke. The casting work is thoroughly up to date, the power plant being a unit with the gearset and the cylinders integral with the crankcase. In working out the suspension of the motor the front support is made up of a yoke with a ball and socket bearing in the front frame crossmember. This is the flexible point, the rigid attachments being by means of arms at the rear of the engine, bolted to the frame by a bracket which carries the transmission case.

In working out the design of the cylinders the trend toward detachable cylinder head has been followed, thus making removal of the valves an easy matter and also facilitating the removal of carbon from the combustion space and from the tops of the pistons. Close-grained gray iron is the material employed for the latter, which are fairly light.

The bearings throughout the motor are of S. A. E. specification babbitt, with bronze backing. The main crankshaft, connecting-rod and gearset bearings are provided with brass laminated shims, and the three main bearings all have the same diameter of 1¾ in. The lengths of the three main bearings are respectively, from front to rear, 3⅝, 2½ and 3¾ in. These carry the high-carbon steel crankshaft which is forged and heat-treated in the Case shops. The finished grind brings the crankshaft to 1¾ in. in diameter. The piston pins are carried on bronze bushings which are inserted directly in the piston boss, and each piston is provided with three Wasson piston rings.

Drop-forged I-beam connecting-rods made, with the rest of the engine, directly in the Case shops are employed. These are of chrome-nickel steel heat-treated to secure the greatest possible strength. The bottom bearing is held in place by four bolts, which are also of chrome-nickel steel.

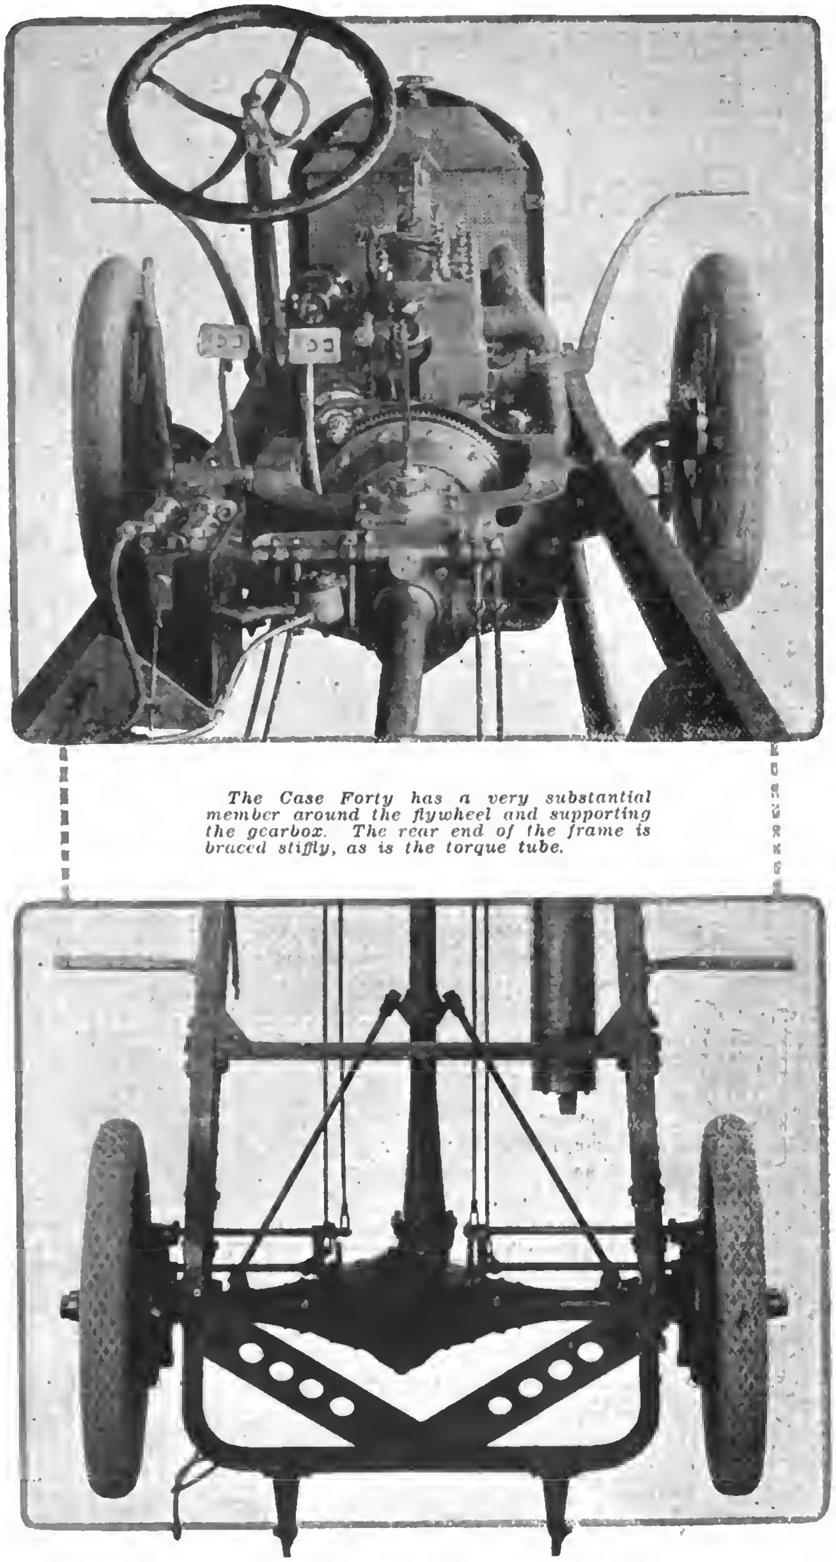
Uses Chain Camshaft Drive

A feature of interest is the care in which the valve drive mechanism has been worked out. The camshaft is driven from the crankshaft by a Morse silent chain and the sprocket on the camshaft is provided with an adjustable hub for changing the timing. The camshaft itself is drop-forged, having the cams and pump eccentric integral parts of the forging. It is supported by three plain, removable bearings and is ground to a final finish. The valves are operated from this shaft through roller type cam followers operated in removable die-cast bushings. The lifters have the standard adjusing feature and the valves are of the regular mushroom type made of 3½ per cent solid nickel steel. The valve diameter is 1⅝ in. with a lift of ⅜ in.

Lubrication is a combined force feed and splash system. The oil is forced to the crankshaft and camshaft bearings and splashed to the piston pins and cylinder walls. The oil pan is of pressed steel and has a 3-gal. capacity, and as already stated, the pump for circulating the oil is a plunger operated from the camshaft by an eccentric. Flow through the leads can be varied by means of an adjustable pressure release, and a pressure gage is provided on the dash which shows, at all times, the pressure under which the system is operating, while there is also a dial depth gage which shows the amount of oil in the crankcase. The leads run directly to the crankshaft and camshaft bearings and the overflow maintains a constant level in the splash troughs, insuring a supply of oil regardless of whether the car is operating on an upward or downward slope.

The cooling system is of standard thermo-syphon design. The radiator is a cellular type of bronze and a notable feature of its construction is that the ordinary soldered joints are not employed, the various members being sealed together instead; giving a core which is more in the form of a casting than of a made joint. The fan is two bladed and of the type commonly known as aeroplane design. It is made of cast aluminum and is equipped with a spring tightener which maintains a constant tension on the belt.

The carbureting and gasoline system is made up of a gravity feed from a cowl tank having a capacity of 14 gal. The carbureter itself is of special Case design and is equipped with a dash adjustment so that variations may be made for temperature and road conditions.



The Case Forty has a very substantial member around the flywheel and supporting the gearbox. The rear end of the frame is braced stiffly, as is the torque tube.

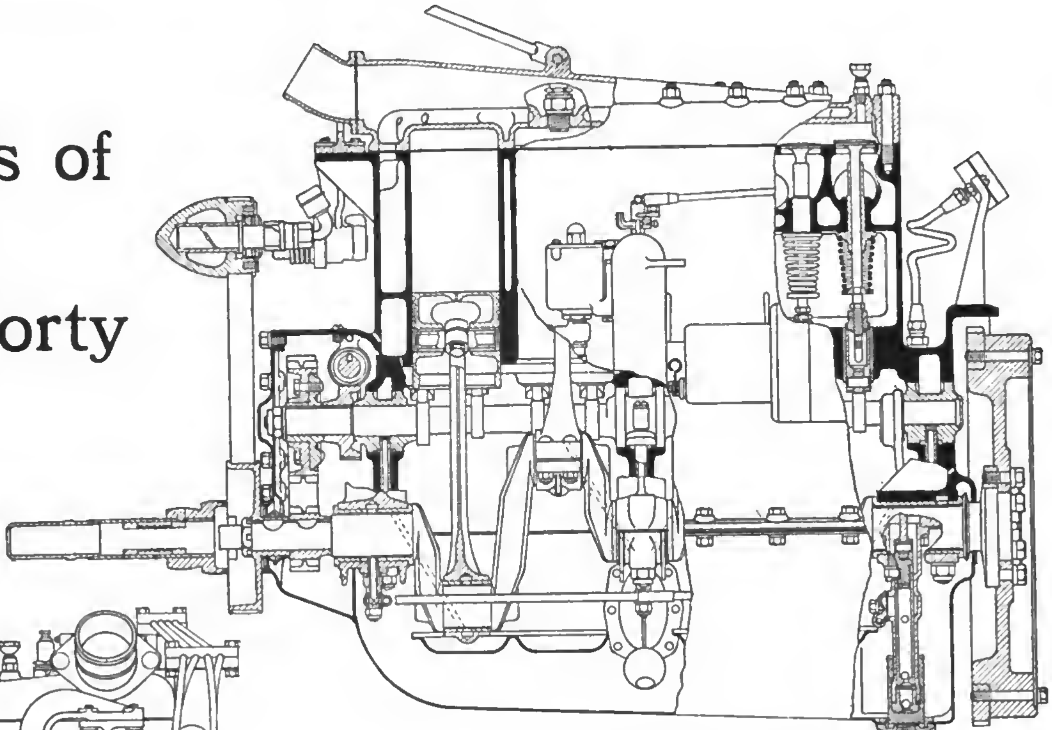
Has Magnetic Pinion Shift

Electrically, the entire car is Westinghouse, ignition, starting and lighting all being provided by this concern. The Westinghouse high-tension distributer is mounted directly on the generator by means of a vertical shaft. It includes the reversing switch feature, by means of which the polarity of the contact points in the breaker mechanism is changed frequently, thereby avoiding the possibility of building up the contact points and the subsequent seizing or irregularity in firing action.

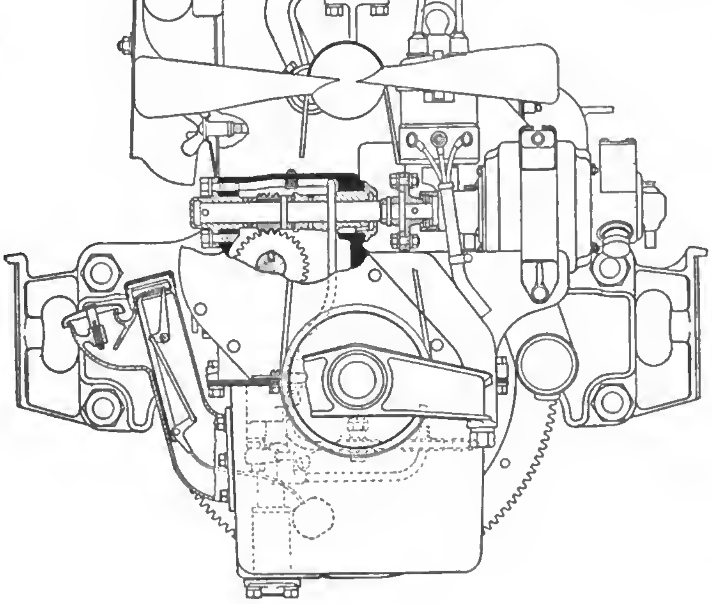
In the starting system contact is made by a magnetically-engaged pinion which meshes with the steel ring gear bolted to the flywheel. This system, as well as the ignition and lighting outfit, operates at 6 volts. The Westinghouse generator is operated at engine speed and has automatic voltage regulation. It is driven by spiral gears from the crankshaft.

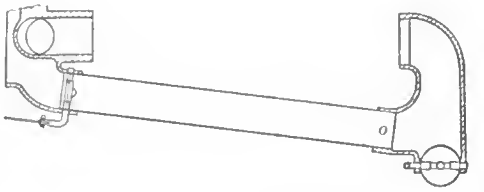
The possibilities of adjustment in the clutch have not been overlooked in the Case Forty design. The pedal has an adjustment to allow for wear, and the clutch spring is provided with means of adjustment to increase or decrease the tension as desired. The cone slides on a splined shaft and the front end of this shaft is carried by an annular ball bearing in the flywheel, which also takes up the spring thrust and

Details of the Case Forty

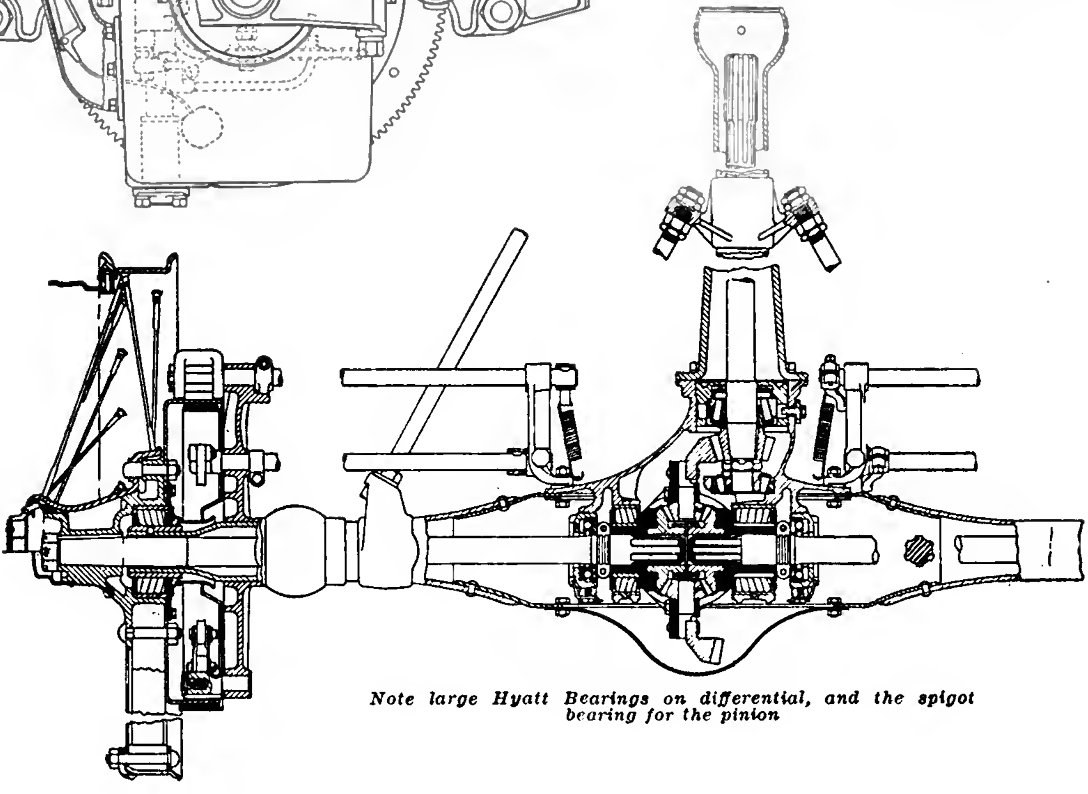


Engine of Case Forty showing chain camshaft drive and cross-shaft for magneto





Special hot air pipe used to cross cylinder block



Note large Hyatt Bearings on differential, and the spigot bearing for the pinion prevents it from being exerted endwise on the crankshaft of the engine. Another point of adjustment is on the clutch brake, which can be so arranged as to stop the travel of the disengaged clutch at any point and with any rapidity desired.

Transmission of Standard Type

From the clutch the drive is delivered to the three-speed selective gearbox, which is arranged to carry the shifter lever in position for center control. This gearbox is a fairly well standardized design, employing Timken bearings and using 3½ per cent nickel steel gears and shafts. Back of the gearbox is a Splicer universal joint connecting the gearset shaft with the main driveshaft. This in turn transmits the drive to a Weston-Mott three-quarter floating spiral bevel rear axle.

Substantial Torque Tube

On the drive layout both the torque and drive thrust are transmitted to the rear end of the gearset housing through a torque tube which is connected with the housing by a ball and socket joint. The drive pinion shaft runs upon two Bock roller bearings, the reduction in the rear axle being 4.23 to 1.

An inverted Elliot type front axle is used, this being of I-beam section, designed and built by the Case company. I-beam section is also used for the steering arms and the steering knuckles and king pins are of special chrome-nickel steel forgings, heat-treated and machined in the Case shops.

Timken bearings are used in the front axle and the steering gear is manufactured by the Jackson, Church, Wilcox Co., under the trade name of Jacox. It is a worm and split nut design and is operated by an 18-in. corrugated wood steering wheel which has the spark and throttle levers on top with the horn button in the center.

Frame Is Extra Deep

The frame is of rather deep section, the greatest depth being at the center, where it is 6-in. At this point the spring hanger for the cantilever rear suspension is attached. This spring is 50-in. long and 2¼ in. wide, and a feature is made of the special analysis steel of which this is composed, the makers claiming that the design of the spring is such that the master leaf is the last to break. The spring is carried on phosphor bronze bushings and follows the line of the frame, the main support for the spring being directly underneath the frame, doing away with any overhanging support.

The attachment to the rear axle is by universal joint, which takes up the side play and allows the spring to attain the maximum flexibility without being hampered by a fixed joint at the rear. The front spring is semi-elliptic, 37 in. long, and also said to be of a design which renders the master leaf or main plate the last to break.

Two sets of brakes, internal and external, operating on 14-in. drums are used. These bolt to the wood wheels, which are equipped with Goodyear detachable demountable rims. The tires are 34 by 4, the makers providing non-skid treads on the rear, and if desired the 35 by 4½ oversize tire can be put upon this same rim.

An all-steel body with divided front seats, adjustable back and forth, is provided and the upholstery is removable, made of grained patent leather. The standard finish of the car is Brewster green with ivory stripe and all the wiring between the body and chassis is brought to one seven-point connector-plug, which enables the body to be detached from the chassis without disturbing the wiring. There are two auxiliary seats which fold back against the sides of the body and are always accessible for service.

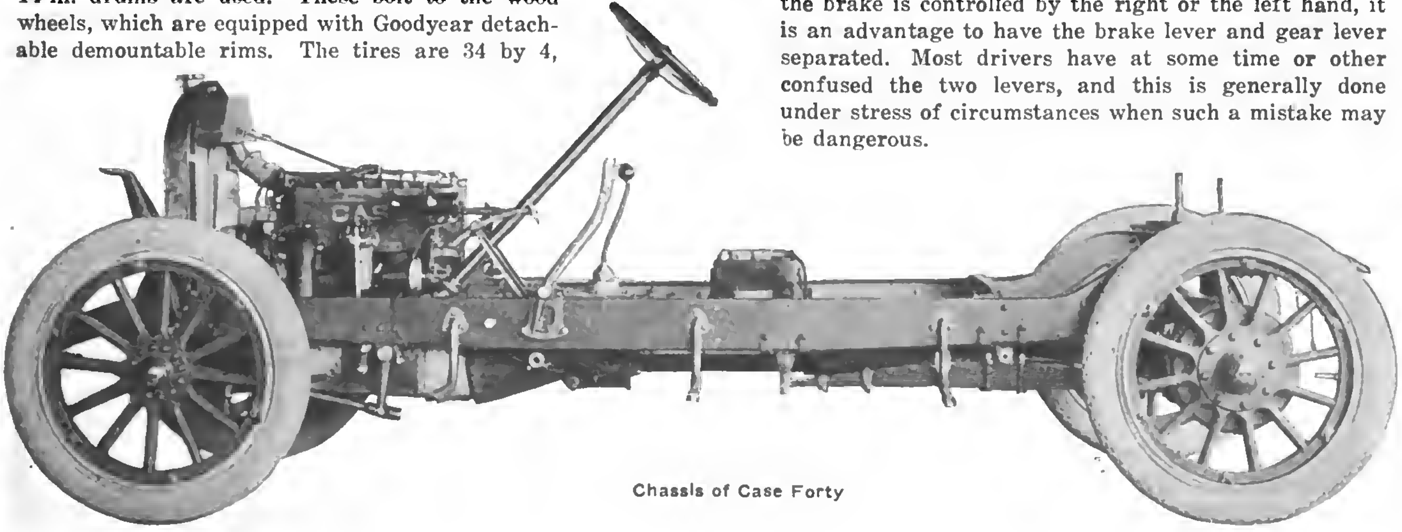
Equipment includes a 6-volt 80 amp. hr. storage battery which is located under the front seat. Thence all the wiring is carried in rust-proof flexible metal conduits. The fuse box is mounted on the back of the combination ignition and lighting switch placed upon the driver's right, being just below the right seat. The headlights are carried on the front fender apron and have a ball and socket attaching device which provides easy adjustment and focus. Double bulb headlights are used with dashlight, inspection lamp and tail light. The dash instruments include ammeter, gasoline gage, and Stewart-Warner speedometer. The windshield is rain-vision, ventilating, tires Goodyear and the top is a one-man design with dust hood and side curtains folding inside. A motor-driven warning signal, a complete set of tools and a tire repair kit are also furnished.

Upholding the Four

The Case Forty is especially interesting, perhaps, because it is one of a now very small class. With the majority of cars at approximately the same price fitted with engines having six or even eight cylinders, the manufacturers of the Case adhere to their belief in the virtues of the four.

To get the best out of the engine no pains have been spared, and it is noteworthy that the design is not laid out so much for cheapness of construction as for efficiency in all ways. An example of this is the use of a cross shaft for driving the magneto. From the viewpoint of accessibility this construction has much to recommend it, but it is unquestionably more expensive than the more usual arrangement. Again, the silent chain for driving the camshaft is not cheap by any means, though it is the accepted practice for all high grade European cars, and for a growing number in America. The body, with its divided front seats is a substantial build with nothing skimped about it either, as to proportions of finish, and the accessory equipment is thoroughly good.

Another point of peculiarity is the mounting of the hand brake lever. In this instance again it would have been cheaper to utilize a central location, but the Case engineers believe that it is an advantage to have the emergency brake operated by the left hand. There is no doubt that whether the brake is controlled by the right or the left hand, it is an advantage to have the brake lever and gear lever separated. Most drivers have at some time or other confused the two levers, and this is generally done under stress of circumstances when such a mistake may be dangerous.



Chassis of Case Forty

Analyzing Engine Cooling

An Accurate Determination of the Factors Affecting Cylinder Cooling and a Quantitative Examination of Air and Water Cooling Comparatively

Results of F. W. Lanchester's Researches Reviewed by A. Ludlow Clayden

ON the question of conductivity it is to be noted that the *pitch of the gills* in terms of the *thickness of the individual gills* at the root, gives the relation of the cross section of metal acting as the conductor in the wall of the cylinder, to the cross section of metal conducting the same heat when the latter has passed into the gill substance, and thus, if the cylinder walls and gills are of the same conductivity, the temperature gradient at the root portion of the gill will be to the temperature gradient within the thickness of the cylinder wall in the same relation as the *pitch of the gills* is to their *root thickness.* Referring to Fig. 5, it will be seen that this is only approximately true, in view of the fact that a small portion of the heat will be disposed of by the outer surface of the cylinder wall itself; however, this is commonly no more than perhaps 10 per cent of the total. If the gill be of uniform thickness from root to tip it is clear that the temperature gradient will be far steeper at the root of the gill than near the tip, because as the tip is approached the quantity of heat to be transmitted becomes less and less, the portion already disposed of at the gill surface being greater. It is evident that a more rational form of gill section will be one tapering off from a maximum thickness at the root where the heat flux is maximum to a knife edge at the periphery where the heat flux falls to zero. In Fig. 6, the heat flow and dispersion is shown diagrammatically.

In connection with the surface disposal of the heat we are not only concerned with the provision of the necessary surface and the maintenance of the necessary air velocity, but it is also obligatory to so design that the quantity of air required to carry away the heat can pass through the jacket air passages; thus if the air passage between any two gills be made of undue length the air will be so greatly heated before it has left the jacket that its temperature difference will be insufficient to make use of the gill surface, although, according to the equation, the latter may be sufficient. The upshot of this is that in the design of the *jacket as a whole*, apart from the design of the *individual gills*, the air channels must be so subdivided and connected in parallel as to pass a quantity of air several times greater than would be theoretically necessary were the air to be raised to the temperature of the gill surface. The factor of importance in calculating the quantity of air necessary is the specific heat of air at constant pressure, which is approximately a quarter that of water, or more accurately 0.24.

The position may be exemplified by the three alternative arrangements of air circulation given in Figs. 7, 8 and 9. In all three arrangements depicted the jacket gills are precisely the same, but in the first arrangement, Fig. 7, it is supposed that the air circulation be taken the complete circumference of the jacket. In the second arrangement, Fig. 8, the air stream is divided, half going one side of the cylinder and half the other, so that for a given velocity over the gilled surface there is twice the total flux. In the third arrangement, Fig. 9, the air stream is divided again, so that now there are four quadrants of the jacket all "in parallel." In this arrangement for a given velocity of air over the gills the flux is four times that in Fig. 7. It will be seen that since the expenditure of energy required to maintain the air blast is due to the skin-frictional resistance of the gills, the arrangements given involve intrinsically the same expenditure power. In other words, it is just as cheap to circulate fresh air over the gilled surface as it is to circulate air which has already been heated, provided the difficulties of design are not insuperable. Where such difficulties exist the "coarseness" of the gills will have to be proportioned to the degree of sub-division found possible, the basis of design being that of the *unit cell.*

The Unit Cell

We have already seen that the heat received by the cylinder walls internally may be approximately expressed, as an average of the whole exposed surface, by a definite number of horsepower per unit area, and that this figure under ordinary conditions may be taken to be 18 hp. per square foot. We have from the equation hp. $= \frac{\theta V}{15{,}000}$ the means of calculating for any given temperature difference and air velocity the rate of heat loss per square foot from the surface of the gills. Thus we have, for any given quantity of heat passing from the working fluid into the atmosphere, a definite relation established between a unit area of the cylinder wall and the corresponding area of the gill surface by which it is served. This at once gives us the relation between the height of the gill, that is to say its radial dimension corresponding to the direction of flow of heat and the spacing or pitch at which the gills are placed, for, referring to Fig. 5, it is manifest that if h be the height of the gill and s be the pitch or spacing, the relation of external to internal surface is approximately $\frac{2h+s}{s}$

The temperature gradient within the cylinder wall is 28 deg. C. per centimeter thickness. This may be taken as a mean value under conditions of ordinary experience; the temperature gradient at the point of maximum heat flux may be, and probably is, at least twice as great. Since the heat conductivity of copper is eight times that of cast iron, this same temperature gradient can be maintained in the gills with a thickness of copper $s/8$. The copper gills in the author's early models were based roughly on this proportion,

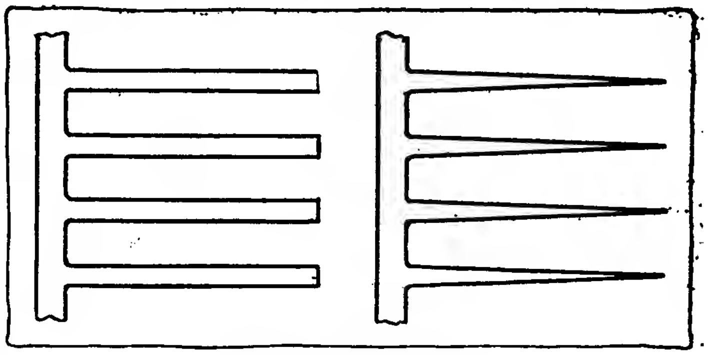


Fig. 5—Types of cooling gill

thus in the gills depicted in Fig. 2 the thickness of copper was 24 s.w.g. or 0.022 in., which is a close approximation to one-eighth of the gill space. In the gills as in Fig. 1 the gill was considerably thicker than here given owing to the difficulty of casting it thin enough; the result being that the thickness as shown is more than appropriate to the conductivity of aluminum. It is by no means necessary, however, that the temperature gradient should be maintained as low as within the cylinder wall; much depends upon the absolute value of h, the radial dimension or height. The thickness of the gill is thus dependent upon the temperature gradient, and upon the conductivity of the metal employed.

Everything points in the future to the adoption of gills of copper or aluminum, as used in the author's early experiments in air cooling. Now the space bounded by two adjacent gills may be regarded as a *unit cell* of the jacket, and the length of this unit cell in the direction of the air flow is determined by the considerations already discussed; if the length is too great the temperature reached by the air before it leaves the jacket becomes too nearly that of the gilled surface, so that the latter will be inefficient. On the other hand, to unduly shorten the unit cell gives no advantage from the point of view of design, and, involves unnecessary weight, or alternatively, too steep a temperature gradient. Making the gills of copper, and designing the cell to give efficient cooling, the height of the gill h should under ordinary conditions be about ten times the pitch, that is $l = 50s$. The unit cell so proportioned is represented to scale in isometric projection in Fig. 10.

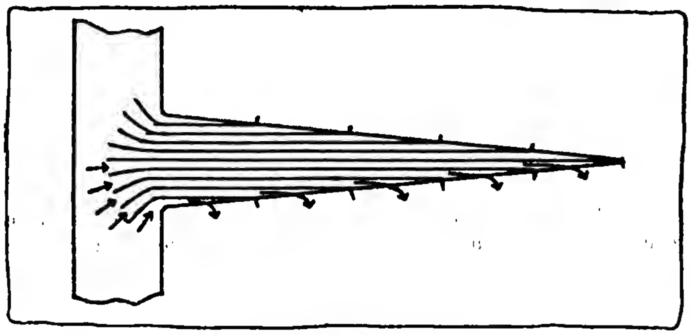

Fig. 6—Flow of heat in gill

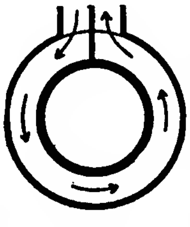

Fig 7

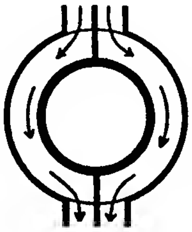

Fig. 8

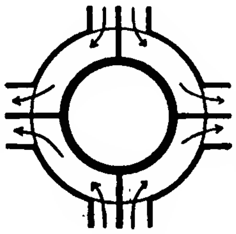

Fig. 9

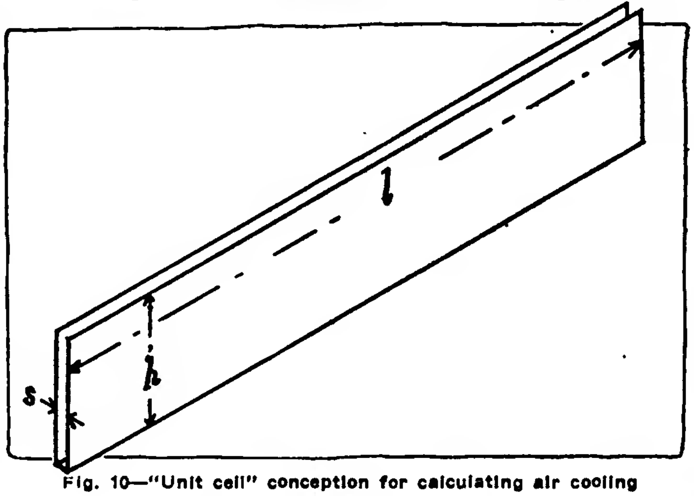

Fig. 10—"Unit cell" conception for calculating air cooling requirements

Practical considerations have very great weight when we consider how best to arrange an assemblage of unit cells to form the cylinder jacket.

It clearly is desirable to sub-divide the jacket as far as possible, and from this point of view the arrangement given in Fig. 8, is better than Fig. 7, and that in Fig. 9, is better than Fig. 8. However, whereas Fig. 8 lends itself readily to design, the air being admitted to one side of the cylinder jacket and escaping from the other side, the arrangement in Fig. 9 is not one which can usually be entertained. If we depart from the circumferential form of cell or gill assemblage, and arrange the gills longitudinally, it then becomes in most cases impossible to sub-divide it at all; the only practical arrangement is to pass the air in at the one end of the jacket and allow it to escape at the other.

Thus we have two alternative arrangements, which are given diagrammatically in Figs. 6 and 12. In the former the assemblage is circumferential, the basis of circulation being that of Fig. 8 and in the latter the gills are longitudinal; the lower figures representing diagrammatically the arrangement contemplated. In the upper portion of the figures we have a diagrammatical development of the cylinder wall, and thus in Fig. 11 we have two blocks of cells in parallel, the length of the cell being the half-circumference of the jacket; in Fig. 12 we have a single block of cells whose width is the circumference of the jacket, and whose length is that of the jacket in its axial size.

It is a significant fact that in the gasoline engine of ordinary proportions, these two arrangements result in approximately the same length of cell, so that, whatever proportion of cell is appropriate to the one arrangement, the same proportion will, roughly speaking, be appropriate to the other. From this it follows that the cell proportions may rationally be expressed in terms of the cylinder diameter, so expressed we have it that

$$l=1.6D$$
$$h=0.32D$$
$$s=0.03D$$

The thickness of the gill cannot be given in terms of D owing to the fact that it is the temperature difference between the root of the gill and the periphery which is the important factor, and thus the conductivity of the gill must be increased in proportion to its linear height. Since the conductivity of the material used is constant, its effective conductivity must be increased by an increase of thickness. From this it follows that the thickness of the gill will have to be proportioned to D^2.

Means of Supplying Air

In the generation of the air current we are faced with two alternatives; either as in the motor bicycle or the aeroplane the natural draught as due to the velocity of the machine may be relied upon, or when the conditions do not permit of this, a fan of some kind must be employed.

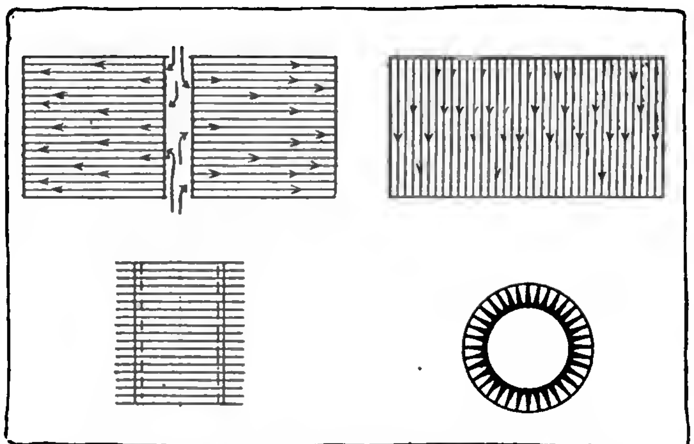
In the author's experimental air-cooled cars centrifugal fans of various kinds were employed.

In the case of the Renault aeronautical air cooled engine, a centrifugal fan, delivering at pressure, is provided for use when it is required to run the engine under stationary conditions, as, for example, when running a bench test, or employing the engine for work other than that for which it was primarily designed.

The centrifugal fan is rarely if ever met with in association with water cooling, the arrangement being adopted being almost invariably that of a screw fan placed immediately behind the radiator. In this position it commonely absorbs at speed from one to two and a half horse power, and at that is scarcely to be regarded as an efficient device.

At this point the preliminary considerations of air cooling were concluded, and the author then passes on to consider the problem of water cooling. The next section of the paper deals with the two systems, forced by pump and convection or thermo-syphon cooling. Later on the two systems are considered quantitatively and it is toward the end of the paper that the deductions are made which enable it to be said that air cooling is the lightest system for engines up to a certain size but not beyond that size.

The paper continues:



Left—Fig. 11—Diagram of air currents in circumferential gill design
Right—Fig. 12—Similar diagram for radial gills

Circulation of Water

The calculation of the quantity of water to be circulated is a matter of perfect simplicity; we must, however, first settle the *temperature difference* which is permissible between the flow and return temperatures of the water as it enters and leaves the radiator. Now the outside limits of this temperature difference are, on the one hand, the boiling point of water, and, on the other, the temperature for the time being of the atmosphere. It is necessary to considerably narrow these limits, however, for the boiling point must under no circumstances be reached, even by any part or portion of the water; and, as to the lower limit, it is clear that the water cannot be cooled down to the temperature of the surrounding air. Thus for a given velocity the cooling surface has to be proportioned to the temperature difference.

Now the boiling point of water cannot be taken at the usual 212° F. in view of the fact that cars are required to go over high mountain passes where the boiling point is considerably lowered. If we take the limit of altitude for ordinary purposes of 6,000 feet the boiling point is roughly 200° F. We may therefore take 200° F. as the upper temperature limit.

Now as to the lower limit; if we regard the highest ordinary temperature of the air to be 80° F. we have the total difference of 200—80=120° F. This difference may be regarded as well on the safe side in view of the fact that although a temperature of 80° F. is not uncommon at sea level it is exceedingly uncommon at 6000 ft. altitude; thus the difference stated may be otherwise expressed as equivalent to a permissible air temperature of 92° F. at sea level.

The above is the temperature difference between *air* and *water*. The temperature difference between the flow and return pipes, on which the water flux must be calculated, is far less than this; 20° F. may be taken as a desirable limit, 40° F. or possibly 50 ° F. should in no case be exceeded.

Where convection or "thermo-syphon" circulation is relied upon, the conditions are too indefinite to permit of ready calculation; the proportions are then usually settied by experience, founded on a rough computation. The main difficulty of accurately calculating the convection circulation is due to the fact that the outlet of the cylinder jackets is commonly at a higher level than the lower terminal of the radiator. If the arrangement were a simple one—an engine at the bottom of a circulation system, and a radiator at the top—the necessary calculations would present no difficulty.

There is one point of sufficient importance to be worthy of mention as touching the relative merits of the pump and convection circulating system. It is often found, after a stiff ascent on a car having pump circulation, that if the engine be stopped, the cooling water immediately begins to boil violently; this never happens in an engine in which the convection or thermo-syphon circulation is employed. The reason for this peculiar behavior is that the rate of heat passing through the cylinder walls into the water jacket is, under any given running condition, constant, and on the engine being stopped the rate of transfer of heat from the cylinder walls to the jacket is not immediately affected because of the heat contained in the cylinder wall itself and so, if the circulation is stopped abruptly, when the engine has been working at full load and the water is near the boiling point, there is an instant ebullition of steam within the cylinder jackets, and a quantity of water may be thereby ejected from the overflow. With convection the circulation current does not stop when the engine stops, and so the generation of steam under similar conditions does not take place.

When convection cooling is adopted the author believes that it is preferable to make no attempt to provide each cylinder jacket with separate circulation. The best results are obtained by connecting the jackets one to the other by apertures as large as found possible, so as to virtually convert the whole of the water jackets into a single tank, and by arranging this tank itself to constitute the return pipe.

Type of Radiator

The history of the radiator shows that a great many types and modifications of detail have at one time and another been tried, and in some cases widely developed.

The questions concerned in developing the best type are numerous and varied. Thus at one time flat tubes had a considerable vogue, and many of our leading firms were fitting radiators in which parallel flat vertical tubes were arranged to connect the foot tank to the "header." Now from many points of view these radiators were excellent, but they possessed one serious disadvantage; in the event of steam being raised and pressure generated in the radiator (an event which may accidentally occur from many causes) the flat tubes, bellows-like, immediately expanded, the air space between them became restricted and the steam generation became more pronounced; finally, the walls of the tubes became pressed one against the other until the whole radiator was practically a solid block and the air passages had ceased to exist.

There is a curious difficulty of an entirely different kind which is sometimes experienced with radiators having round tubes. When in such a radiator the pump delivery is brisk the turbulence produced in the header may be so great as to cause numberless eddies and to result in intereference in the flow of water down through the tubes; the eddies give rise (after the manner of the waste pipe of a bath tub) to vortices forming over the tops of the tubes which draw down columns of air. The effect of this is nearly as bad as if the water were to boil, for not only does the air so sucked down displace a quantity of water which is lost through the overflow, but the said air within the cylinder jacket and surrounded by water at near the boiling point is swollen to many times its natural volume by the high temperature and by the water vapor taken up, and when in due course it comes through into the header the result is hardly to be distinguished from actual boiling. It has come to the author's knowledge that such cases have been cured by providing for a *reduction* of the pump discharge.

(To be continued)

The Sizes of Motors for Trucks and Outline of British Practice in this Field

By W. D. Williamson

Part 2—Outline of British Truck Motor Design

(*Continued from page* 504, *issue of March* 16)

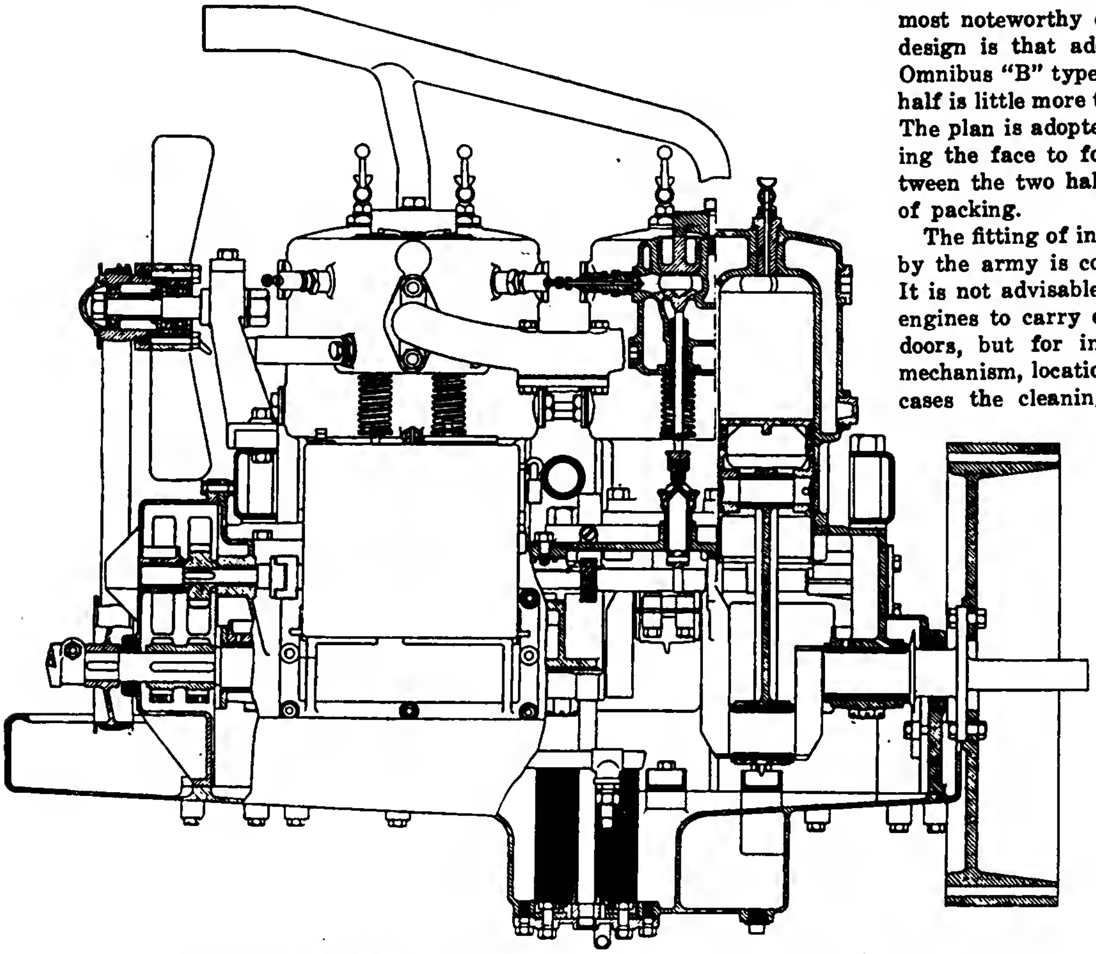


Fig. 13—London General Omnibus "B" type, with very shallow crankcase

CYLINDER DESIGN—Cylinders cast in pairs are the rule.

Austin cylinders are separate castings, however, and the Albion (Fig. 8) is a monoblock.

Ample water jackets with carefully considered arrangement round the valve pockets and stems are found in most modern engines. The plan adopted in the Napier and Pagefield engines of having the cylinders cast with large openings in the jacket at top and sides simplifies molding and insures the jacket cores being thoroughly cleared. With the ordinary small core plugs it is often almost impossible to clear the jackets about the valve pockets.

Crank Cases

Crankcases differ very little in design from those in pleasure cars, although more robust. The usual practice is to split the case horizontally on the center of the crankshaft, carrying the bearings in the upper half, and to use the lower half principally as an oil retainer and dust excluder. External ribs on the lower half, although they may be of distinct advantage for oil cooling, are not general. Perhaps the most noteworthy departure from the usual design is that adopted in London General Omnibus "B" type engines, where the lower half is little more than an oil tray (Fig. 13). The plan is adopted in this engine of scraping the face to form an oil-tight joint between the two halves without the necessity of packing.

The fitting of inspection doors as required by the army is coming into general favor. It is not advisable or even possible in most engines to carry out repairs through these doors, but for inspection of the internal mechanism, location of trouble, and in some cases the cleaning or removal of the oil filter, they are very useful. Any tendency they may have to weaken the case is usually overcome without special provision by the extra metal required for the facing and to carry the studs.

Oil Indicators

There appears to be room for a reliable oil indicator for the dashboard, of somewhat stronger construction than the usual patterns, for use on commercial vehicles.

Engine Suspension

Experiments the author has made show that for any distortion that might occur under normal conditions the ordinary underframe method of construction is quite sound. It appears to be more satisfactory than extending the crankcase arms to the main frame.

In one experiment made with a 4-ton chassis having the engine on a sub-frame, the engine was started and throttled down so that it just continued to run. The near side front wheel was then gradually raised. When the wheel was 12 in. clear of the ground, no difference was discernible in the running of the engine. From 12 in. to 15 in. the twisting of the frame did have an effect, and at the latter height the engine showed signs of stopping. The engine was switched off, and when tested at the starting handle was found to be stiff with the clutch either in or out. The chassis was gradually allowed to fall back again, and at 12 in. the whole of the stiffness had disappeared.

Standing at the back of the chassis, the shape and twist taken by the near side long member of the frame made it appear that three point suspension is more important for the gear box than for the engine. The front of the chassis was

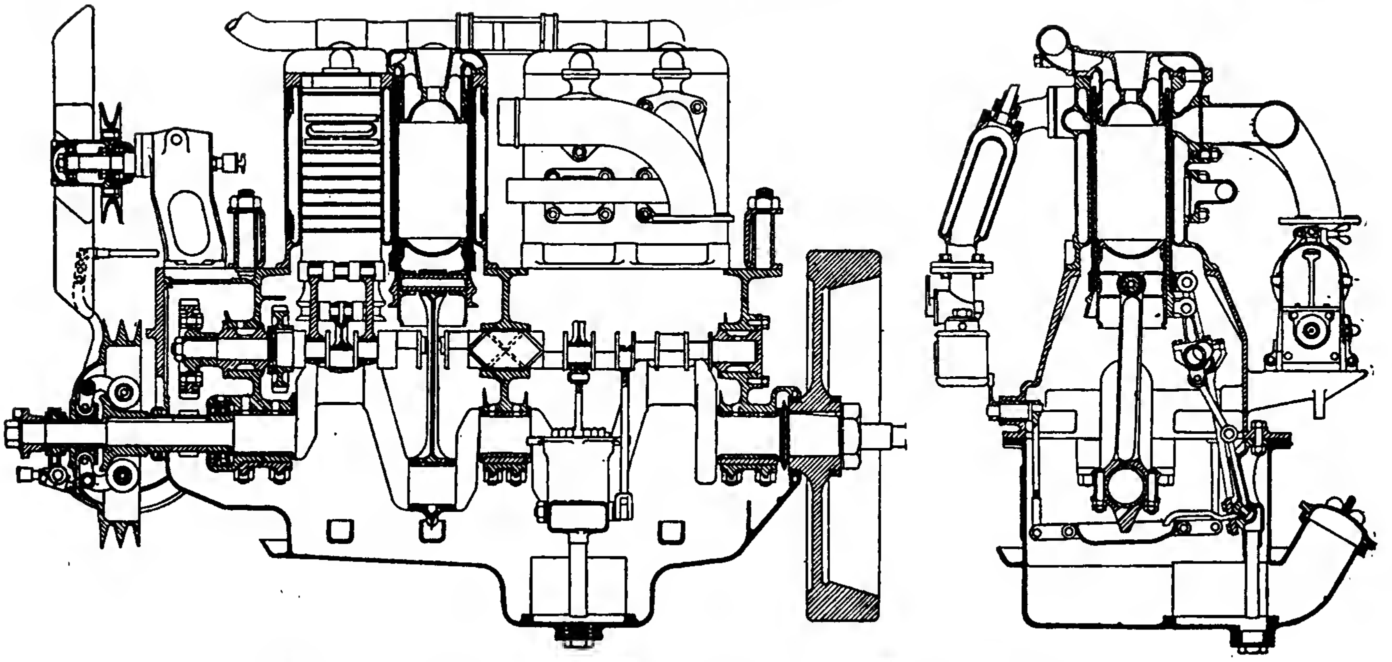

Fig. 14—The 110 x 150 Daimler sleeve-valve motor for commercial vehicle service

tilted on to the off side front wheel, and no doubt helped by the fact that the front spring acted in some measure to restrain the bending of the side member in front, very little distortion was apparent in front of the dashboard. The greatest change of shape was encountered between the dashboard and the front bracket of the rear spring, where the frame was both bent and twisted.

Cooling; Radiator Design

The problem of cooling a commercial vehicle engine, which appeared to present considerable difficulty only a few years ago, has now been satisfactorily solved. Ample water jackets and pipes of larger bore have helped to overcome the original troubles. Lorries now work under the most severe conditions without showing signs of boiling. Practically all cooling systems embody a circulating pump, and this pump is invariably of the centrifugal type. Cooling fans are of robust design, and in most cases mounted on standard type ball bearings. A fan with arms and boss cast in aluminum in one piece, secured to a malleable iron center to serve as the fan pulley, appears to be the most satisfactory type.

The fan driving belts are often much too light for the work they have to perform. They have to transmit quite an appreciable power, and in addition are subject to shocks when the engine speed is altered quickly. The positive drive for the fan in the Hallford is specially worthy of attention.

Turning to the radiator, the type in most general use is the tubular, formed of vertical water tubes soldered to tube plates, and having top and bottom boxes of cast aluminum. Opinion seems to be divided as to whether the tubes should

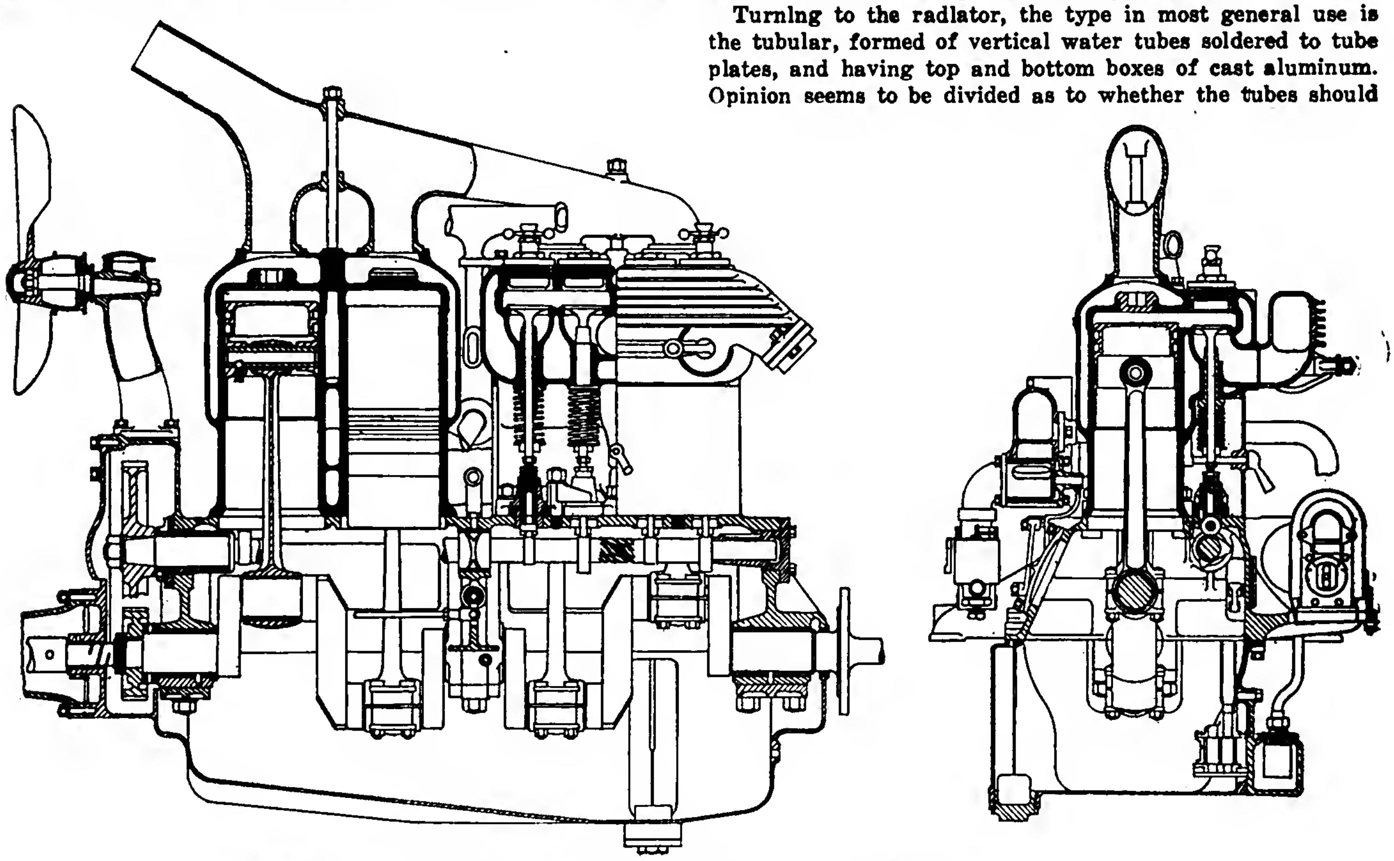

Fig. 18—Sections of Dorman engine, army truck type. Hollow fan bracket used as oil-filler duct

or should not have gills, although the general practice favors gills. The usual tube is of 26 gage brass or copper, 5/16 in. external diameter with gills 15/16 in. diameter or 15/16 in. square, soldered in position at about ⅛ in. pitch. Experiments carried out by a large maker of radiators showed the most useful ratio of gill diameter to tube diameter to be three to one. In these experiments where ½-in. tube was used with 15/16-in. gills for appearance instead of 1½ in., the efficiency fell approximately 10 per cent.

Where plain copper tubes are used they are usually ⅜ in. external diameter by 28 or 30 gage.

Further experiments went to show that the relative efficiency of gilled to plain tubes is about three to one. In other words, three times as many tubes are required in a tube stack having plain tubes as in a stack having gilled tubes. [The many details needed to make the results of these experiments fully convincing—dimensions of air channels, for example, being an important factor—are not given by Mr. Williamson.] Trouble with tubular radiators usually occurs where the tubes join the tube plates, and the reduction of the number of joints, and consequently of the possibility of leaks, is a strong recommendation for the gilled tube type. The gills, in addition, help to stiffen the tubes and afford some measure of protection against damage by impact.

When makers of vehicles commenced to deal with the trouble of insufficient cooling, the tendency at first was to err on the other side. In some cases very large radiators were fitted, having more cooling surface than is now found necessary. Current practice is very well represented by the following formula for a four-cylinder:

Bore in in. × stroke in in. × 8 = feet of 5/16 in. tube with 15/16 in. gills.

This formula does not take into account variations in cylinder design, disposition of valves, and other factors, but it has the advantage that it is easy to handle and gives a result which can be relied upon for satisfactory cooling.

There are engines in commercial vehicles with cooling surface considerably less than that given by the formula. In one case the cooling surface was carefully cut down, starting from bore × stroke × 7, and at bore × stroke × 6.2 the limit appeared to be reached beyond which it was unsafe to go.

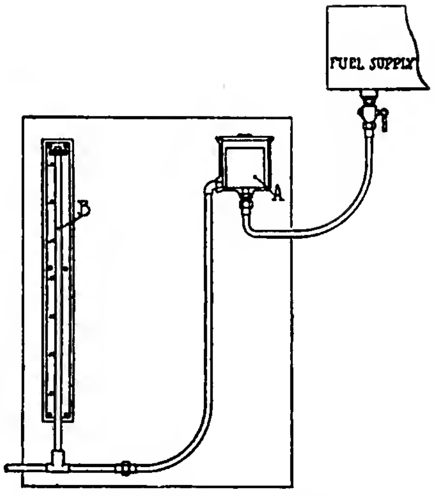

Fig. 17—Dorman Fuel Consumption Gage

A Fuel Gage

The apparatus used in making the consumption tests of Dorman engines while not entirely new is of sufficient interest to merit a description.

The apparatus, Fig. 17, consists of a float chamber "A" arranged so that at rest there is a constant level of gasoline in an open-ended glass tube "B." When gasoline is drawn away to the carbureter, the velocity of the flow past the lower end of the pipe "B" causes the level in this pipe to fall. This fall is constant for any given velocity in the horizontal pipe, but varies with this velocity. Consequently, on a suitably calibrated scale, it is possible to read off the flow of gasoline in any units.

The scale is graduated to show pints per hour, so that the consumption can be obtained instantly.

The advantage of thus being able to ascertain the effect of even the most minute alteration to the carbureter setting will be readily understood.

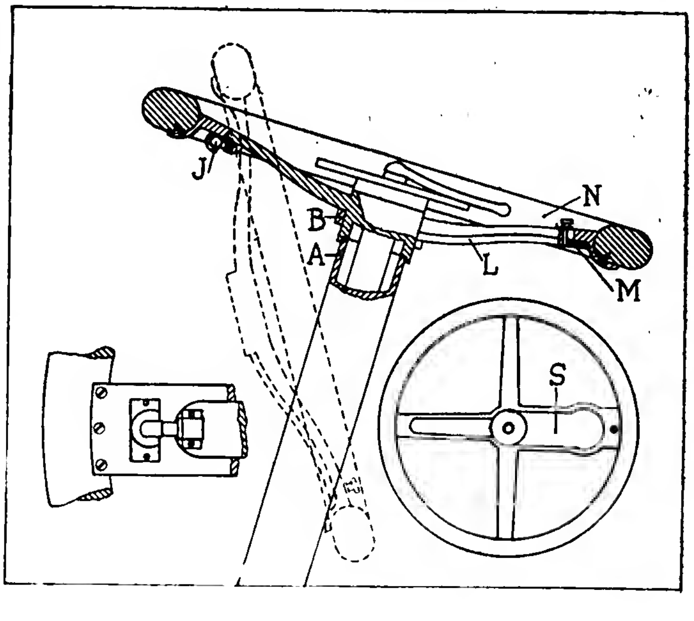
A New Steering Wheel

In view of the widespread interest in room in the driver's seat an invention recently brought out by a California man, is noteworthy. This is a pivoted steering wheel which has for its object the provision of more room for entrance into the driver's compartment, thus allowing him to use the left door, which on many cars is of little value. Another object of the invention is to provide a steering wheel having a universal joint connection with the steering shaft, whereby the wheel may be turned on the universal pivot and moved out of the way of the driver irrespective of the position of the front wheels of the car. The patent was issued to William A. Fraser of Los Angeles, under date of Feb. 22, 1916. Its serial number is 1,172,696.

Referring to the illustration, a vertical section through the steering wheel is given which clearly illustrates the method of operation. The wheel shown is of conventional design mounted on a hollow shaft through which the throttle and spark adjustments are made. On the top of the steering tube proper *A* there is a collar *B* to which the wheel is attached when it is in the running position. The wheel is provided with a slot *S*, so that when it is swung down about the ball and socket joint *J* the column does not interfere with the movement of the wheel, as it is cleared by means of this slot.

There is a spring member *M*, which is mounted in the recess which holds the wheel in its position when the driver is operating the steering mechanism. The dotted position of the wheel in the drawing shows the space occupied when the driver desires to enter or leave the seat. When it is desired to leave the seat the steering wheel is simply pushed out of the way against the tension of the spring member, thereby operating the latch part *L*.

When it is desired to tilt the wheel laterally, in the event of the front wheels being turned in one direction or the other, the steering wheel may be tilted one-quarter turn.



Timken Adds New Forge Shop

New Building to Contain All Drop Hammers Includes Large Tool Room

THE latest addition to the ever-growing plant of the Timken Detroit Axle Co. is a new forge shop. Profiting by its experience in the forging of weighty pieces on a large quantity basis, the Timken Company laid out its new buildings, which are located across the street from its main works, so as to take advantage of all the light and to bring about utmost efficiency in the making of this highly specialized class of parts. In fact, the new forge differs in many respects from most of the plants of this type.

The feature that is first to attract attention is the unusual height of the hammer room. This is not only with the idea of giving much light and air, but also to make possible the installation of a craneway above the tall hammers. The forge building and the die shop are really one long structure, although the die part is somewhat lower than the forge proper. The buildings have a total length of 650 ft., with the forge part 380 ft. long by 70 ft. wide and the die making room 40 ft. wide. The total interior height of the forge shop is 54 ft., this giving an idea of the room that was provided for the crane.

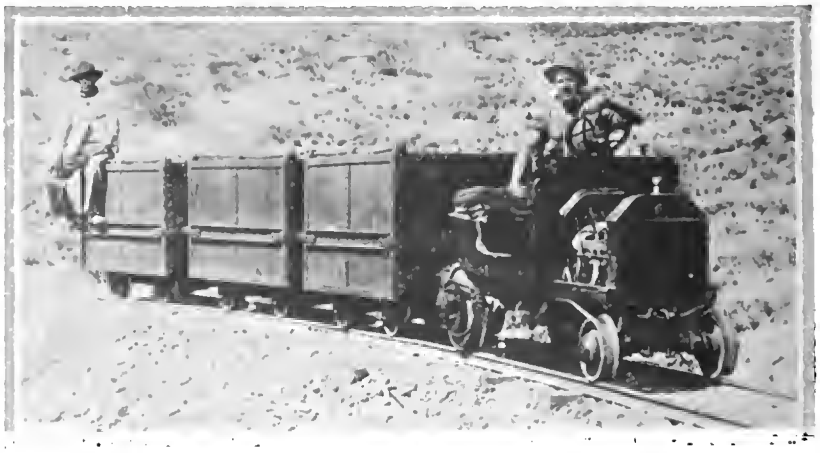
In the forge shop, the hammer equipment consists of thirty-one steam drop hammers of capacities ranging from 1500 lb. to 7000 lb. These are arranged along the outer wall near the windows that extend all the way up and comprise practically the entire wall, and hence the hammer men get a maximum of light and air. Considerable foresight was displayed in the placing of the furnaces for heating the parts to be forged, and in the location of the trimming presses with respect to the hammers. These trimmers have been put at about the positions the furnaces usually are placed, and the latter are arranged at the side of the hammers. When the air blows in from outside, it therefore does not first pass the furnaces before reaching the men, and hence there is no chance for it to become heated. The trimmers do not interfere with the free circulation of cool air. Motion study also had something to do with this placing of the hammer auxiliaries, for it was found that less time was lost in having the men swing around with the heavy forged pieces that had to be trimmed than would be consumed if they had to carry them to one side of the press. Placing the hammers and furnaces in the same line also made it possible to use a monorail satisfactorily in the manipulation of the very heavy pieces that must often be forged. This monorail carries a hoisting apparatus that is worked by hand.

The overhead crane has a capacity of about 40 tons, and it is of immense assistance in the placing of large dies in the hammers and for carrying hammer parts or other heavy machinery as well. When a piston or piston rod must be removed from a hammer, the crane again plays a useful part, for it cannot only pull these out of the hammer cylinder, but can transport them to the point where they are to be repaired. It is surprising that overhead cranes of this kind are not found more frequently in forge shops. Of course, the building must be laid out to accommodate such a device, but the service is of inestimable value.

In the construction of the new plant, ample provision was made for the proper foundations for the immense hammers, and the result is a plant that is strikingly free from jarring and shaking usually attendant upon huge hammers where foundations are none too solid. The concrete foundation running the length of the forge room and under the hammers is 5 ft. thick, while a special setting is given the hammers on 12 by 12 oak timbers that are set endwise and are 5 ft. long. These are bolted together and give a base for the big machines that allows a certain amount of cushioning with utmost rigidity.

Running the length of the center of the forge shop and in a tunnel measuring 8 ft. deep and 8 ft. wide are all of the pipes carrying the steam to the hammers and the exhaust away from them, the oil supply lines that feed the oil-burning furnaces, and the compressed air that goes to the machines. The hammers are oiled from a central supply tank of 75 gal., it being fed in pipes to each machine under steam pressure. Six 200-hp. Wickes boilers supply the power for the hammers. The coal for these is stored in overhead bins, and is fed to the boilers by an ingenious system of cars that operate on a runway and can be brought into position to send the coal into the hopper of any of the boilers as required.

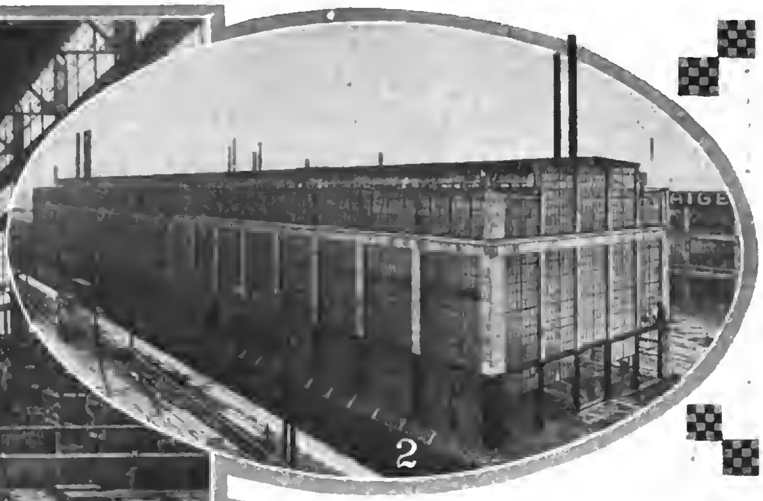
In the handling of stock that is going to the hammers and in the conveying of the finished forgings to the manufacturing departments, an interesting system is employed. The steel stock yard is located at the side of the plant, and a 5-ton crane brings whatever materials are required to a side entrance to the forge building where it is deposited upon an electric truck that conveys it to the hammers. A powerful shear is also conveniently placed in this stock yard for the cutting of the stock to the right length before it is transported to the hammers within. Finished forgings are placed in steel containers that are kept near the hammers, and when one of these has been filled, the overhead crane picks it up and deposits it on one of the electric storage battery trucks. It is then conveyed down an incline in the front side of the building and through a tunnel under the street that leads to the manufacturing departments opposite. Thus there is little or no delay in handling the forgings.



THE Presidio Mining Company has had in successful operation for more than a year a Ford automobile for hauling ore from its silver mine at Shafter, Texas, to the reduction mill. The car is equipped with low, steel flange wheels and runs upon a regular tram track. It is stated by E. M. Gleim, superintendent of the company, that it has proved to be one of the most inexpensive methods of ore transportation that could have been devised. The cost of operating the car, including upkeep, is nominal. It hauls on each out-going trip from the mine three two-ton side-dump cars, or a total load of about 16,500 pounds, without difficulty. The trock is of about 3 per cent grade.

Drop Forge Plant for Timken Axles

1



2

THE object of drop forging is to eliminate machining on the final products. A front axle, a connecting-rod or a large bevel gear blank would cause much waste of material, time and labor if cut from the solid bar. Thus it is economical to spend lavishly upon the plant for making and using drop forge dies. The first few hundred pieces struck by the die pay for the apparently high initial cost. The Timken Co. have one of the finest forge equipments and a large proportion of their front and rear axle parts come from the hammers almost in their finished state.

Delage Cars Make Strong Team

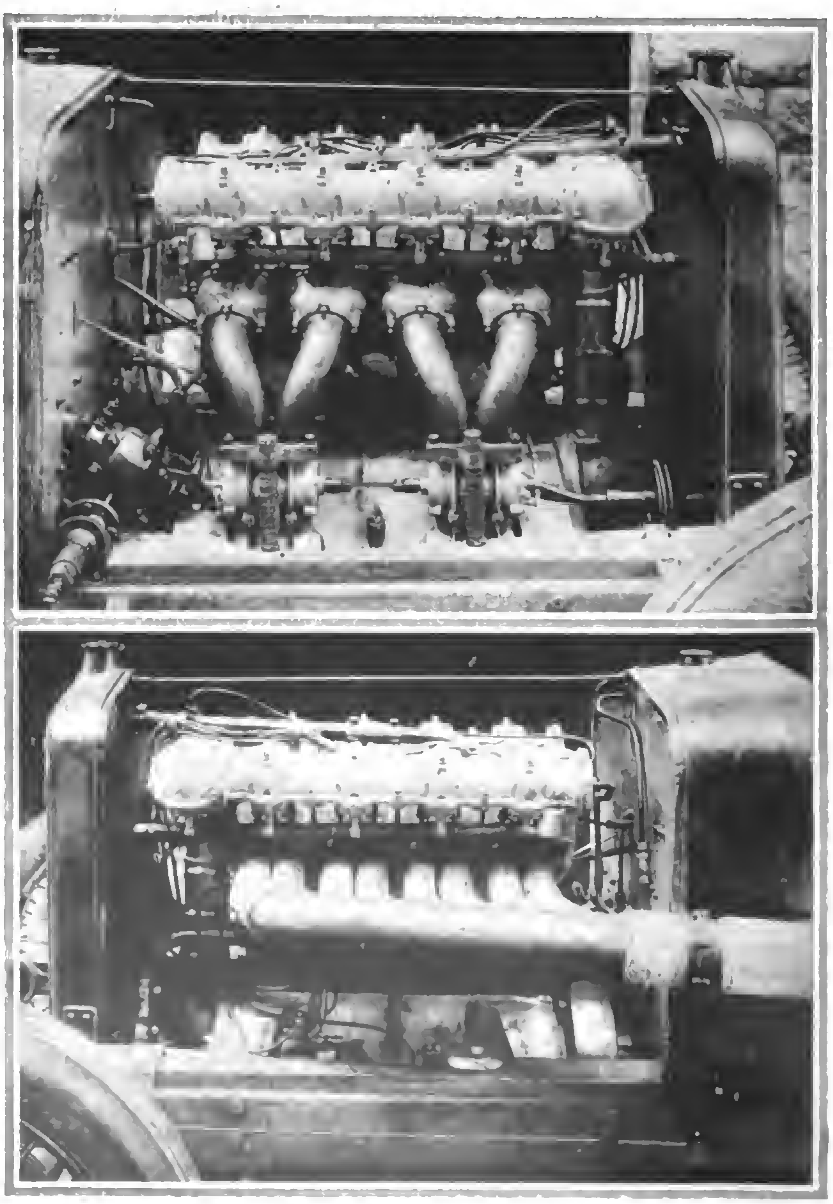
Harry Harkness Has Newest European Racing Cars — Have Run Only One Race—Should Be in Perfect Condition For the Speedways

As announced in THE AUTOMOBILE last week, the three Delage cars which took part in the last French grand prix are now in New York, and will make their appearance on the speedways very shortly. These cars have been imported by Harry Harkness, and will be managed by Carl Limberg, who will drive one of them. Drivers for the other two are not yet picked.

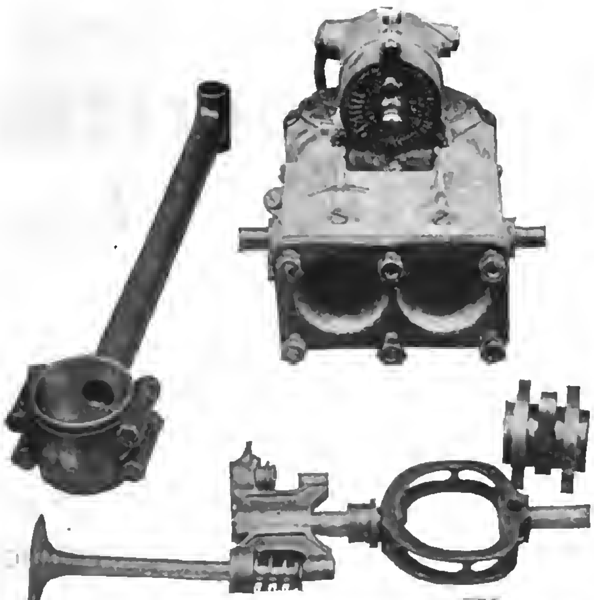
At the time of their first appearance, these cars were wrapped in much mystery, their details being kept very secret. Gradually it leaked out that their especial novelty was a set of sixteen poppet valves, each of which was both shut as well as opened by a cam, the spring forming only a cushion. Exactly how this was done has never been allowed to escape, though some diagrams were obtained showing the principle. One of these was published by THE AUTOMOBILE on July 9, 1914, and the photograph of the actual parts on the page opposite shows that the actual pieces are very much like the diagram. There are three cams to each pair of valves, the midmost lifts the valve by pushing down a stirrup that surrounds the cam, and the two outside cams bear upon the side pieces of the stirrup and pull the valves shut, acting through two springs.

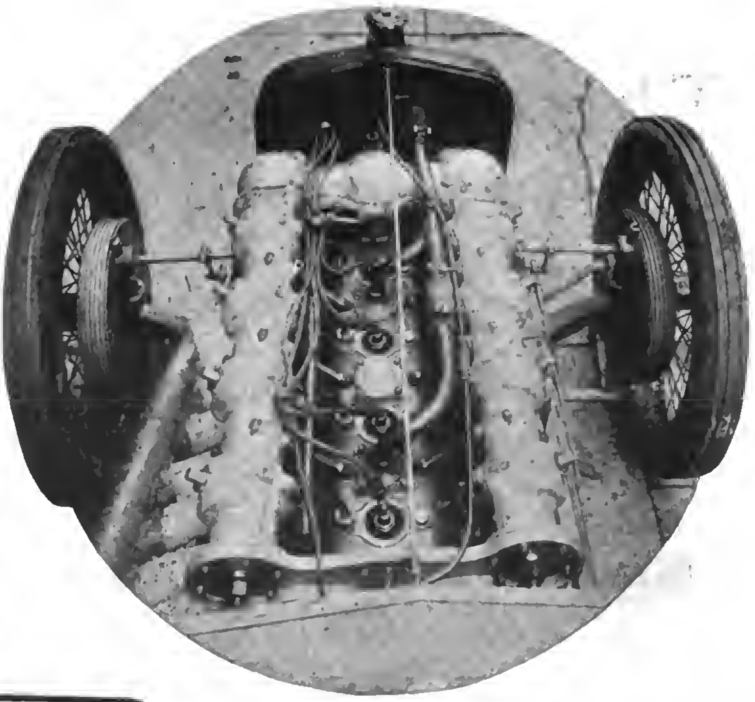
In the practice spins before the race Bablot, who had one of the trio, astonished the fans by making a lap in minutes less than most of the others, and from that time onward the Delage team was reckoned to be about the fastest in the field. On the race day, however, some petty maladjustment of the carbureters made at the last moment upset all calculations, and the Delages did little to justify the high hopes of their backers.

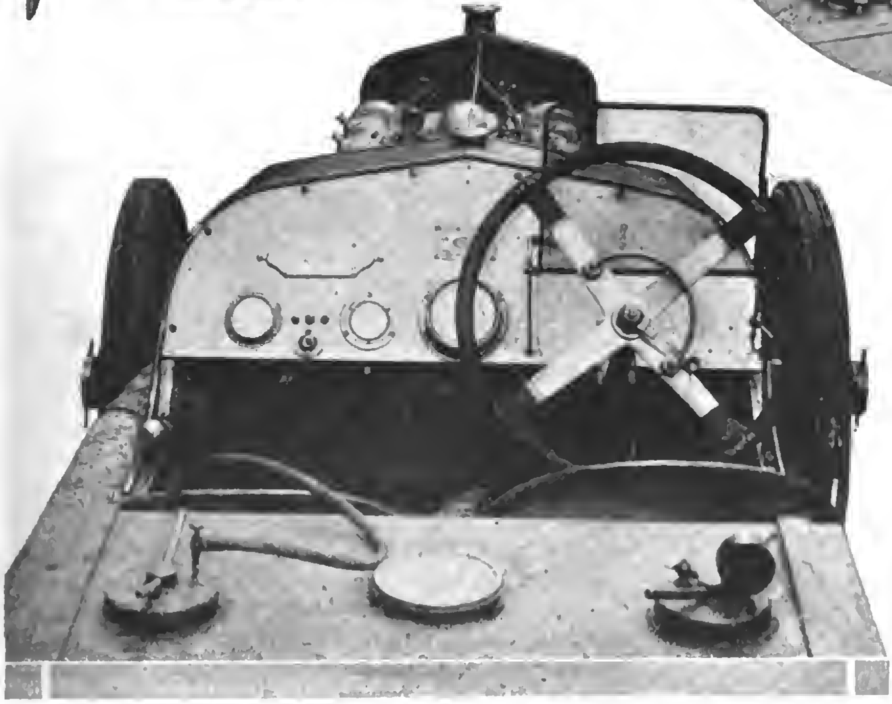
Still everyone recognized that it was an accident, and that it was no fundamental fault that had caused the trouble. Since July 4, 1914, the speed machines have been resting under a coat of oil. They are essenially as good as the day they left the factory; they are more nearly new than any European car in America to-day.



Alternate sides of the Delage engine giving a good idea of the valve mechanism







Above—Details of the valve gear, the cylinders and the hollow connecting rod. Below—The driver's view of the car. The long plate above the gages on the left is a lap recorder to be worked by the mechanic

Thus it is reasonable to expect great things of the team.

The photographs herewith show more detail of the cars than has so far been published. It will be seen that the two camshafts are driven by a single vertical shaft with a nest of bevel gears at the upper end, the spark plugs being in the center of the cylinder heads. A small peculiarity is that the cylinders are bolted on from beneath the studs fitting in the cast iron foot with the nuts inside the aluminum crankcase. The valve mechanism shown just beneath the cylinder has the stirrup turned at right angles to its proper position so as to show the whole part in one photograph. There are two Claudel carbureters on each engine, operating simultaneously with throttles interconnected.

Because of the very hilly nature of the last grand prix circuit in France five speeds are provided with direct on third, and the nature of the road also dictated the use of the large front wheel brakes. In addition to these there are a pair of brakes on the rear wheels and a transmission brake as well.

The engines are well within the 300 cu. in. limitation being 94 by 160 mm. or 3.7 by 6.3 in. This gives a piston displacement of almost exactly 270 cu. in. The wheelbase is 106 in., and the tires 34 in diameter on Rudge Whitworth wheels.

At present the bodies are little more than seats, as the many curves of the French course made the value of streamline tails quite doubtful. Just back of the seats there is an immense tank for gasoline and oil, the latter being fed by hand pump when desired, and circulated in the engine by a centrifugal system. It is planned to inclose this tank, and to provide each car with a body more suited for speedway racing.

Being more nearly new, the Delage team ought to prove much more formidable than did the Peugeot team last year, as in the latter the only really new car was Resta's, the others being already well worn. It is unquestionable that the presence of this new trio will make a substantial difference to the keenness of competition on the speedways this coming racing season on the speedways.

From an engineering viewpoint it will be very interesting to see how the latest Delage engines stand up to the strenuous requirements of speedway competition. Originally these cars were designed for road racing on a course where gears were shifted almost every quarter of a mile for a third of the circuit, but there was one very long straight, over eight miles, where speeds of 110 miles and over could be attained. There was a long hill, where the engines could revolve at their maximum speed on the lower gears, but there was a descent giving quite a respectable rest to the motors at the end of the long straight.

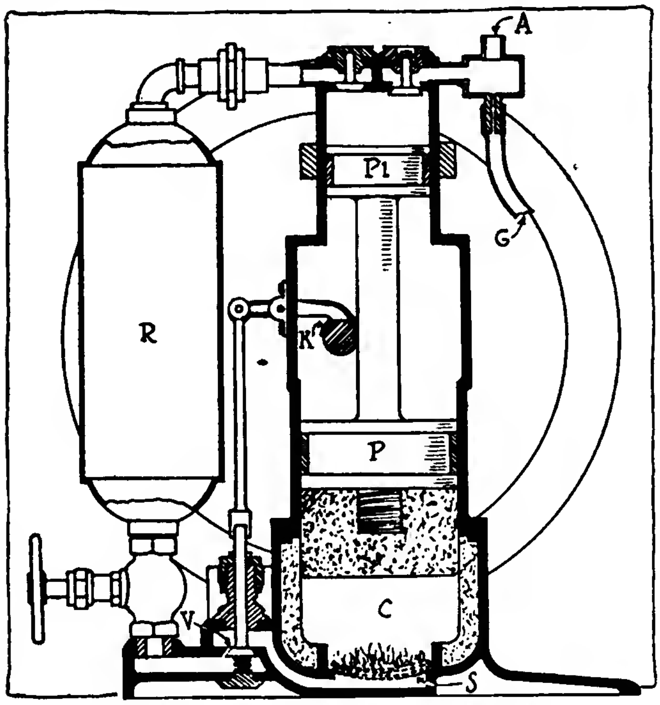
On the speedway where there is no rest period the conditions are more difficult for engine durability, but since the Peugeot engines proved equal to the stress, there is every reason to expect a corresponding performance from the Delage cars, and these machines were undoubtedly faster than the 1914 Peugeots when opened out to the full. They are almost sure to win something.

The History of the American Automobile Industry—22

Transition Period Between Old and Modern Development—Brayton Engine Taken by Selden as Basic Was Last Stage Before Otto Type Which is Used Universally Today

By David Beecroft

THIS week we reach what might be termed the transition point between the past and the present so far as the history of the development of the gasoline or explosion engine, as we know it to-day, is used. This installment brings us to the engine patented and built by George B. Brayton of Boston, Mass. The patent was taken out April 2, 1872, and the engine known as the Brayton was the popular and accepted type from that date until 1880 or later. Brayton had been working on his engine for over 20 years; in fact, from a few years after Stuart Perry issued his patents.



BRAYTON'S TWO-CYCLE ENGINE 1872

This engine with a single vertical cylinder used a compound piston, the lower portion P known as the working piston, and corresponding with the piston in a gasoline engine to-day and the upper portion Pl serving as an air pump to pump a mixture of air and an explosive gas into the larger reservoir R where it was stored under 60 pounds pressure. The reservoir was of approximately double the capacity of the cylinder. From this reservoir gas was admitted into the combustion chamber C through a poppet valve V. This valve was opened by the cam K through the medium of a rocker arm and vertical tappet. In the bottom of the combustion chamber C was a series of five or six thicknesses of wire mesh covering the large opening in the cylinder base. The mixture of air and gas entering the cylinder under pressure had to rise through these meshes. Above the meshes was kept burning a constant flame and which ignited all of the incoming gas. The piston P was driven upwards by the expansion due to the heat from the burning of the gas rather than from any explosion. The air pump piston Pl drew a mixture of air in through the opening A and the mixture of illuminating gas or some hydrocarbon vapor through the opening G. These were drawn in at the ratio of 12 volumes of air to 1 volume of explosive gas. In the top of the cylinder were the usual valves for regulating the openings between these pipes A and G and the reservoir R. Owing to the constant fire in the bottom of the cylinder it was necessary to carry on the bottom of the piston a substance such as soap stone capable of sustaining a high degree of heat without injury. The combustion chamber was also lined with a similar material. The illustration does not show the engine as being water-jacketed but in actual use it was water-jacketed.

It was in connection with the final settlement of the famous Selden patent suit in January, 1911, that the public got its first general introduction to the Brayton engine. The judges in that decision stated that George B. Selden based his patent on the Brayton engine which naturally Selden thought would be the eventual one for all automobile uses. Later events proved otherwise, and that the Otto design, which will be described later, was the real pioneer of the present explosion engine as we know it to-day. Had Selden selected the Otto design instead of the Brayton the American automobile industry would to-day unquestionably be paying its royalties. However, Selden in selecting Brayton in preference to Otto took the wrong direction, and while his patent was declared valid by the courts in 1911 it was also decided that the present type of explosion engine used in automobiles did not infringe it, rather that our engine to-day sprang from the Otto type.

Before describing Brayton's engine we should first realize that it was not an explosion engine as we understand it to-day. It is true Brayton ignited a mixture of air and a combustible gas, the mixture being a 12-to-1 ratio, but Brayton in his patent makes it particularly plain that the expansion in his cylinder was not an explosive force on the piston, but "a true pressure due to expansion on account of the fact that the piston is at the very commencement of its stroke when the expanding gases begin to act upon it." Brayton had the idea that the pressure as obtained in steam engines was the one for explosive engines.

Further: Brayton did not employ a carbureter device such as we understand it, but rather used a storage tank in which he mixed the air and gaseous vapor. He pumped them into this storage tank and kept them under pressure. He then let this explosive mixture flow into the working cylinder under its own pressure. As soon as the mixture entered the bottom of the cylinder it was ignited by a flame which kept burning all of the time. He did not have ignition as we understand it, but simply a constant-burning flame. Brayton had a regulated intake valve much as we understand it which controlled the entrance of the explosive mixture into the cylinder. This valve was opened and closed by a combination of cam, tappet, and springs, quite similar to systems employed to-day.

Brayton had to have with his engine an air pump which kept the reservoir filled with a mixture of air and explosive vapor under a uniform pressure. This air pump was really a part of his motor so that the piston of the air pump was really a continuation and integral portion of the piston in the working cylinder.

Not Strict Explosion Engine

It will thus be seen that although Brayton's engine proved a popular one in the 70's and gave every indication in those days that it might develop into the possible engine to be used on automobiles, still it was not a strictly explosion engine, but bore a striking resemblance to steam in that the charge of air and gas was carried in a separate reservoir to be drawn upon as necessary, just the same as steam is carried under pressure in a boiler and drawn upon as needed. Brayton did, however, get away from one feature of steam, namely, he used a single-acting piston; that is, the explosive mixture was admitted at one end of the piston only as is done to-day. Steam engines are double acting; that is, the steam enters at each end of the piston, and up to Brayton's time all inventors of explosion or gas engines used the double-acting system. Brayton thus marks the first radical step in departure from the double-acting engine to the single-acting engine of this date.

Brayton's engine was constructed in a thoroughly mechanical manner, and was unquestionably the best explosion engine yet produced. It, therefore, began to win approval wherever shown and one was exhibited at the Centennial Exposition in Philadelphia in 1876, where it was utilized to pump air for the Aquarium.

A section of the Brayton engine illustrated herewith shows its general scheme of operation, with its compound piston, the lower portion *P* forming a working piston and the upper portion *P I* being an air pump to store the mixture of air and explosive gas in the reservoir *R* under a pressure of 60 lb. The crankshaft does not appear, but how the engine was worked out can be judged from an external view of it, also shown. A very large-diameter flywheel was used. The mechanically operated intake valve *V* opened by the cam *K* through a rocker arm and tappet appears. The spring to close the valve is also shown. When this valve was opened the mixture from the reservoir *R* immediately rushed in to fill the space *C* below the piston, but on entering the piston through the large opening at the base it had to pass through five or six fine mesh screens. Above these screens was a constant ignition flame, also supplied with gas from the reservoir *R*. Thus the gas rising through the screens or mesh started burning and it was this burning coupled with the pressure of the gas that raised the piston. There was not any sudden explosion as we know to-day, but rather Brayton relied on the expansion due to the heat from combustion.

When starting the engine it was first necessary to open the throttle wheel shown below the reservoir *R*. The constant flame for ignition was next ignited. This done, the large flywheel was turned over by hand until the valve *V* opened. The inrushing gases then began burning and the pressure lifted the piston. The momentum of the flywheel was then sufficient to carry the piston down until the valve *V* was again opened. Thus the cycle of operation was continued. There was no cycle of operation, as we know it to-day, that is, induction, compression, explosion and exhaust. There were but two cycles, combustion and exhaust. When the engine had to be stopped the hand throttle wheel was turned, shutting off the supply of mixture from the reservoir *R*. The heat expanded the air to a much larger volume so that although working at a pressure no higher than the air pump pressure it, because of the larger piston area and larger volume, would not only drive the air pump piston but yield considerable power available for work besides.

Used Accurate Oil Pump

Brayton developed an oil pump that, although not of delicate construction, permitted accurate adjustment of the oil supply and to a large extent governed the engine by varying the amount of oil admitted. His great problem, of course, was to get a proper mixture and to continue the combustion from one admission of air to the next. His

The FORVM

ANALYZING FRONT END OF CHASSIS—SPRING ACTION AFFECTS STEERING—FUNDAMENTAL FAULTS IN CONVENTIONAL DESIGN

Faults in Front Spring Suspension

By H. H. Dyke

THE forward spring suspension of an automobile, to be mechanically correct, must serve three purposes: First, to act as a cushioning buffer between the front axle and the frame; second, to prevent side sway or lateral movement of the front axle and wheels relative to the frame and body; and third, to permit the spring or cushioning movement bebetween front axle and frame to take place without interfering with the proper action of the steering connection. A front spring suspension that does not do these things, and all of them, is mechanically defective.

The front axle suspension in substantially universal use to-day is illustrated in connection with the usual fore and aft steering link in Fig. 1. This arrangement prevails in 95 per cent or more of the maker's designs. There are several other types in use, to be sure, but this is practically standard construction.

This standard type fulfils the first and second conditions referred to above admirably, though even as to this a substantial improvement could be made at little or no additional expense. This improvement could be secured by the substitution of a pull shackle for a push shackle at the rearward end of the spring, as is already done in some makes of trucks and has been adopted just recently in at least one make of passenger car and as sketched in Fig. 2. A pull shackle naturally takes the right position, but a push shackle is always canted as far as it will go to one side or the other, and wear, once started, progresses with great rapidity. Any worn front spring bolt which has been in use with the type of suspension illustrated in Fig. 1 will be found to be worn as in Fig. 3. Such wear is due to this canting action of the push shackle.

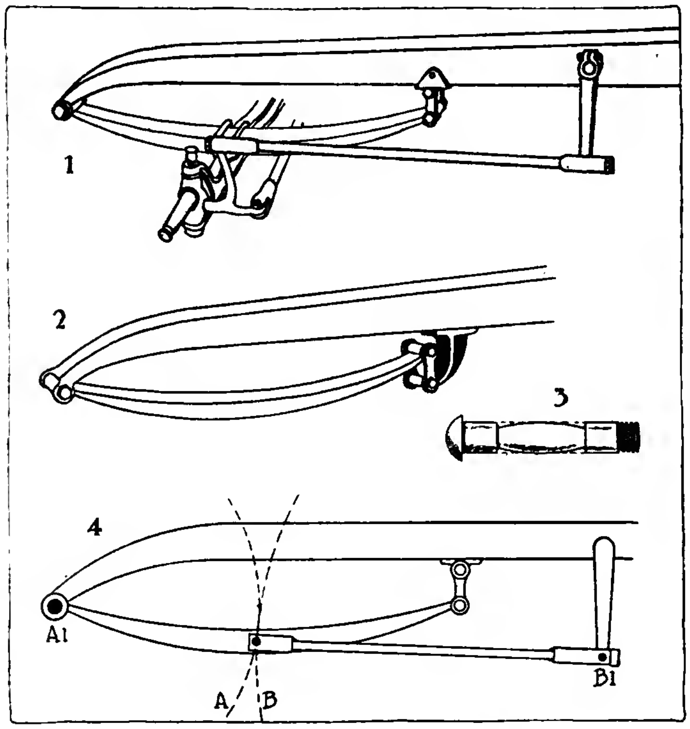
The Cause of Wobble

But where the type of either Fig. 1 or Fig. 2 fails, is in the third of the enumerated essentials for a front spring construction. Proper steering action is very seriously interfered with. With such arrangement the front wheels wobble from side to side every time they move up and down.

The steering connections enter into this matter along with the front springs and axle. The standard arrangement of steering connection from frame to axle, in all fairly good sized cars, at least, is to place the steering gear well back in the frame, with the steering link at its rear end pivoting on the steering gear arm and running forward from the steering gear arm to the steering knuckle arm on the front axle, and it may readily be assumed that this construction will remain standard, for with any alternative construction, the steering link must run crosswise or partly crosswise of the car, which is obviously undesirable.

The cause of the wobbling action of the front wheels is shown graphically in Fig. 4. It is due to pivoting the front axle by the forward ends of the springs to the extremities of the horns projecting forwardly from the frame about 18 in. *in front* of the axle and placing the steering gear on which the steering link pivots about 2½ ft. *back* of the axle, thus bringing these two pivotal centers nearly or quite 4 ft. apart. When there is any up and down spring action the front axle moves in the circle A because the spring has a fixed pivot at its front end at A′, the center of A, and the knuckle steering arm carried on the axle should naturally move in the same path A. The forward end of the steering link which is pivoted to the steering gear arm at its *rear* end would naturally move in the circle B which has B′ for a center, but the knuckle steering arm on the axle and the steering link are fastened together and must move together notwithstanding the upward and downward divergence of their separate natural paths.

How is this accomplished? The answer is rather complicated, for it is divided into a number of parts, but take the worst situation first. If we have a snug fitting, irreversible steering gear and a steering link without the customary flexible connections at its ends, the point or center B′ is fixed, and the forward end of the steering link and the end of the knuckle steering arm attached thereto must move on the curved line B notwithstanding the axle to which the latter is secured by the king bolt moves on the curved line A. Thus for any up and downward spring movement of the front wheels and axle there is also a wobbling or turning move-



Figs. 1 to 4—Analysis of front suspension ment of these wheels from side to side, just such a movement as you would get by grasping a front tire and turning the wheel back and forth pivotally on the garage floor, the car standing still meanwhile. This pivotal movement is responsible for much of the wear on the front tires. The best way to see clearly what this means is to examine the track of a car which has passed over a soft spot in the road where there is a deep hole causing excessive spring action. The front wheels make drunken tracks, which are covered only partially by the straight tracks of the rear wheels and show alternately on each side, this drunken wake gradually fading out and disappearing as the spring action decreases.

In ordinary practice, in addition to this castor or pivotal or wobbling movement of the front wheels the conflict of the circular paths A and B is distributed in several other places. The flexible socket joints in the two ends of the steering link take up some of it. The point B′ is never absolutely fixed in practice, but there is play in the worm and worm wheel of the steering gear, and this accounts for some of the movement, and, incidentally, is a prominent factor in steering gear wear; and finally, the steering wheel itself, particularly where the gear is not irreversible, turns every time there is any spring action between the front axle and the frame or body. Watch the steering wheel of any car with a bevel steering gear and you will see how the steering wheel turns every time you hit a bump with the front wheels. This has much to do with the popularity of the irreversible type of steering gear.

The present standard construction has, of course, certain advantages or it never would have attained its present almost universal use. It is simple and strong. The front axle is pulled by the spring and not pushed by it. It is generally considered to be of good appearance. At least the car-wise public has gotten used to its appearance and is satisfied on this score. The public acquiescing, car manufacturers have come to regard it as "good enough," and undoubtedly its substantially universal use is dependent on the fact that car makers are averse to trying to force something on the public which it does not want. Once the public comes to know the various evils that are inherent in this mechanically incorrect type of front spring construction, however, the wobbling of the front wheels, the extra wear on the front tires, the extra wear on the steering gear, and particularly the movement of the steering wheel itself making driving harder and more tiresome than it should be, we may begin to look for a different attitude and a demand for a construction which will do all that that now in use will do, but which will not have its many disadvantageous and unmechanical features.

Suggests Elimination of Left Door

By K. F.

J. E. SCHIPPER'S article has opened a very old subject for discussion from which we can all learn something by airing our opinions. Several comments are that the designers are overlooking the comfort of the drivers. This may be in a few cases, but I am sure if there is not some comfort in the cars the designers would have heard from the sales-manager a long time ago. Even if they have picked out a good average condition they will have had an adverse comment from some of their sales branches.

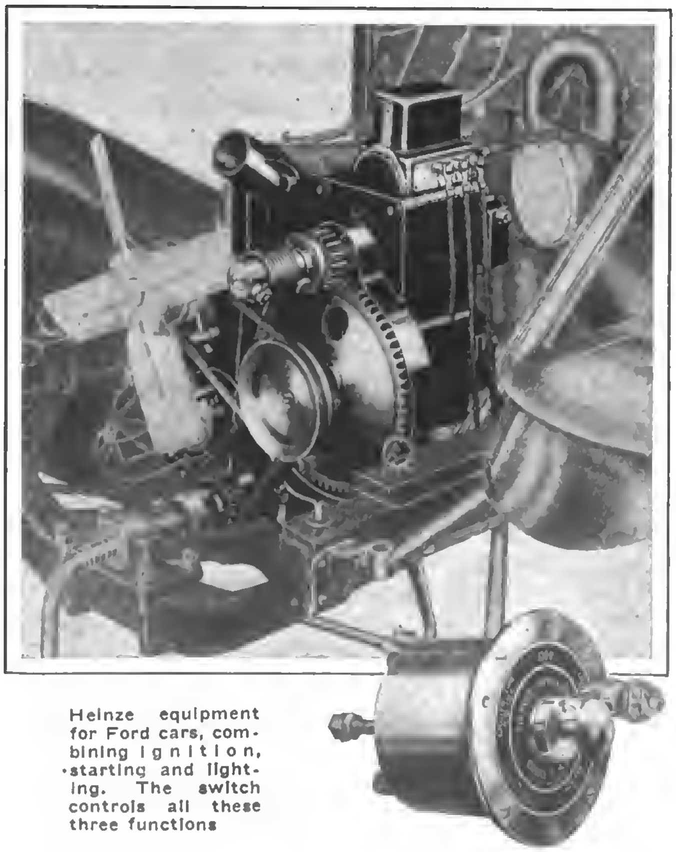
Room under the steering wheel, graduation of the cushion, hardness or softness of the trimming will be discussed as long as we turn out cars, and there will be a difference in opinion somewhere. Some cars permit of giving their customers a better range than others; some permit of adjusting these elements, but where the greatest rub comes, is in the highly developed cars that sell for a very low price and are made in large quantities. These are designed with every piece and fraction of an inch of material considered, as the hundreds of parts that go to make a car, with an excess of even a small amount on them multiplied by the thousands that are to be made of them comes to a very formidable figure. The wonders that are being accomplished with tin, imitation hair, and leather are seen everywhere in happy parties on all roads. They are testimony to the highest skill in industry.

In the modern cars the steering wheels are larger and the sides higher. The size of the wheel and seats being fixed, then unless the doors are made to open up the entire side of the seat or nearly so, we have the condition of a squeeze through for the driver if he wants to get in from the left side. On the cheap cars who not eliminate the left front door.

Heinze Installation for Fords

A TWO-UNIT electric lighting and starting system for Ford cars incorporating the Bendix automatic drive has been put on the market by the John O. Heinze Co. of Springfield, Ohio. The starting motor is a simple series-wound machine of the four-pole type designed to be compact and light. It is operated by a starting button dash switch, which completes the circuit and causes the automatic Bendix drive to mesh with the intermediate gear mounted on the generator shaft. This is connected to the crankshaft by silent chain through which the cranking drive is transmitted.

The Heinze-Springfield generator is driven by the chain through which the final starting drive is obtained. The generator is also a four-pole instrument, shunt wound and designed to deliver 6 volts. The cut-in speed is quite low, the maximum charging rate being attained at 10 m.p.h. The regulator is mounted separately in a small box on top of the starting motor. The installation is clearly illustrated on this page. A feature of interest is the dash switch which controls lighting, and ignition as well as starting.



Heinze equipment for Ford cars, combining ignition, starting and lighting. The switch controls all these three functions

The Rostrum

Timing of Sheepshead Bay Packard

Editor THE AUTOMOBILE:—How were the valves timed in the 102 m.p.h Packard used by Mr. Vincent at Sheepshead Bay?

2—What compression was used? What is formula for figuring same?

3—What is the valve timing of the special Stutz and Duesenberg motors?

4—Why do some motor manufacturers open intake valve before closing of exhaust?

New York City. J. B. W.

—The Packard used at Sheepshead Bay had its exhaust valve open 60 deg. instead of 45. The latter figure is standard on the Packard Twin Sixes. The inlet valves remained open 50 deg. late instead of 35 deg. The exhaust valve closed 40 deg. late and the inlets opened 9 deg. late, the same as standard. The valve lift was 7/16 in. instead of 5/16 and the pistons were crowned to give 90 lb. gage compression at 120 r.p.m. The standard motors carry 75 lb. compression.

2—This is answered under question 1 partly. Compression pressures are not figured by formula as a rule but tested by gage, as the theoretical compression is never equal to the true compression because the gas in the cylinder is not compressed either isothermally or adiabatically, but somewhere between the two.

3—The timing of the Stutz and Duesenberg motors was published in THE AUTOMOBILE for Feb. 3 on page 234.

4—So that the valve shall be fully open during the effective part of the suction stroke.

Manufacturers of Four-Wheel-Drive Busses

Editor THE AUTOMOBILE:—How many are there and what are the addresses of manufacturers making a four-wheel-drive truck, something large enough to put a hotel bus body on that would carry about fifteen passengers? What are the prices of same?

Plentywood, Mont. J. A. K.

Fifteen passengers, at 150 lb. each, close to the average, will weigh about 2250 lb. A bus body will weigh about 1200 lb. The total load will be 3450 lb. This load is not net, however, as you must subtract at least 500 lb. body allowance, leaving a net load of 2950 lb. This will leave a liberal baggage allowance on a 1½-ton chassis.

Four-wheel-driven trucks of 1½ and 2-ton capacity are made by the following, for the prices per chassis given:

Duplex—Duplex Power Car Co., Charlotte, Mich., $2,800.
F. W. D.—Four Wheel Drive Auto. Co., Clintonville, Wis., $3,600.
Hoadley—Hoadley Bros., Gosport, Ind., $3,000.
Robinson—Golden West Motors Co., Sacramento, Cal.
Weier-Smith—Weier-Smith Truck Co., Birmingham, Mich.
Jeffery—Thos. B. Jeffery Co., Kenosha, Wis., $2,750.

Kink for Putting Tires on Rims

Editor THE AUTOMOBILE:—After an unsuccessful attempt to put on a quick-detachable tire which would not allow the two q.d. rings to be put into place, I tied the shoe together in five or six different places, using strong brown cord for the purpose. This brought the two beads of the shoe close together and when I put the tire on the rim, the two q.d. rings were easily slipped into place without the use of a hammer. The pieces of cord were then cut and pulled out and the tire inflated. This scheme is particularly valuable when reliners are used. I make my own reliners out of the fabric of my discarded shoes, allowing a small strip of the tread rubber to remain on the finished reliners and I get over 10,000 miles of service out of my tires and no punctures or blowouts. Such reliners must, however, be carefully made and must have all edges well fastened down and new inner tubes must be used.

If strips of rubber from a discarded inner tube are placed between the leaves of springs, it will stop squeaks and will add wonderfully to the riding qualities of the car.

A very annoying rattle difficult to detect on a Ford car and which sounds like a mudguard rattle, is really caused by the brake rod striking against the rear support of the running board. This noise can be stopped by securely fastening a piece of rubber or fabric around the brake rod at the point where these two parts come together.

Brooklyn, N. Y. E. H.

Timing 1907 Fiat for Road Racing

Editor THE AUTOMOBILE:—I have a 1907 four-cylinder Fiat which I want to use for road racing. Bore is about 5⅛, stroke about 6¼. It has 36-in. wheels and is geared 2¼ to 1 on fourth gear.

1—What size and how far apart should I have holes in skirts of pistons?

2—Would it be worth while to bore holes in connecting rods? Would they stand it?

3—I can enlarge intake and exhaust valves ⅜ in. Is it worth while enlarging intakes?

4—Will you show drawing with dimensions of best cam action possible for my motor?

5—Can I enlarge intake and exhaust ports of my cylinders?

6—Are the Su-Dig spark plugs for obtaining two simultaneous sparks from a single point magneto successful?

7—Can I increase the stroke of this motor? If so, where can I get a suitable crankshaft?

8—Would it be advisable to set plates in cylinder heads to increase compression?

9—Is there any way of obtaining a vacuum in the exhaust pipe? I understand that some Mercedes racing machines had a sort of inverted megaphone attachment on the exhaust pipe that caused a suction at higher speeds.

Will you kindly offer any suggestions that may occur to you so that I may obtain a speed of 100 m.p.h. or better?

Great Neck, L. I. J. A. R.

1—Use ½-in. holes at least 1 in. apart.

2—This has been done with the result of lightening the rod ¼ lb.

3—Yes, this would help if it could be done.

4—This is a matter for experiment and one which THE AUTOMOBILE cannot handle without opportunity for making tests.

5—This is inadvisable.

6—Yes. It would probably be advisable to use a double magneto for high speed work.

7—It can be done but it is almost certainly inadvisable.

8—It is not necessary to increase the compression on this motor.

9—By arranging the exhaust to secure an injector action an injector effect can be created. The actual value of it is debatable.

There are two principal things which will help you in addition to obtaining more power. First, cut the weight wherever possible, and secondly, examine and adjust every bearing throughout the transmission and wheels so that the car rolls as lightly as possible. A good racing car can be moved with one finger on a smooth road.

Information on Stewart Vacuum Feed

Editor The Automobile:—Kindly give me the following information about the Stewart vacuum gasoline system.

1—Why is it that the vacuum tanks vary in size? I have seen some that looked about twice the size of others. As the tank is being filled as fast as the motor needs gasoline, I should think that the small size would work equally well, and have the advantage of light weight and compactness.

2—One of the advantages claimed for the Stewart system is the positive flow of gasoline on steep grades. But as the vacuum tank is placed on the inside of the dash in many cars, this being quite a distance from the carbureter, what advantage has this as regards the flow of gasoline over having the main tank in the dash?

3—Does every car have the vacuum tank so placed that it will work perfectly on the steepest grade a car can encounter?

4—What is the percentage of commercial vehicles having the Stewart system? R. B. W.

East Orange, N. J.

—Vacuum tanks vary in size because certain motors require larger capacity in the lower chamber of the vacuum tank than others do.

2—Gasoline flows from the reservoir chamber of the vacuum tank into the carbureter by gravity just as it flows from the cowl tank into the carbureter. However, it is usually possible to locate the bottom of the vacuum system higher above the carbureter than the bottom of a cowl tank. The vacuum system is particularly advantageous in that it allows the gasoline tank to be at the rear of the car.

3—As far as we have any record, no case has yet been reported of a car so equipped encountering too steep a grade.

4—Probably between 40 and 50 per cent.

Torsion Moment of Motor Shaft

Editor The Automobile:—I want to cut down the weight of a gasoline engine as much as possible. Can I replace a flywheel which is 2 ft. in diameter, the rim alone weighing 200 lb. with a flywheel which is 4 ft. in diameter, the rim alone weighing 50 lb. and get the same results? I am following the law of momentum. Is this correct?

2—If a shaft weighing 12 lb. to the foot has a transmitting capacity of so much power, would it take a shaft of same material weighing 24 lb. to the foot to transmit double power? In other words, is the size of one shaft to another as the powers are which they are to transmit?

3—Does adhesion of driving wheels become smaller or less as the speed of the automobile increases? Why? In other words, does an automobile become lighter to the ground and in what proportion?

4—Have you published anything on the subject of advantages and disadvantages of 12 and 6-volt lighting systems for automobile use in The Automobile? If so, what number of magazine?

5—Comparing engines one of 10-in. stroke, the other of 5-in. stroke and using same quantity gas, leaving other things aside, what would govern speed of engine? Is the expansion of a small volume of gas at a certain temperature the same as a large volume at same temperature?

6—What are the pressures at different points of a lever 100 lb. being applied at A? O. T.

Jersey City, N. J.

—Yes, the laws of momentum are followed.

2—The strength of shafts are not related in the way you state. The beam formula $M = \frac{S\ I}{c}$ can be applied to the shafts as it has a close analogy to the torsion formula, the letter M indicates the torsion moment in this case, S the maximum strength of the material, I, the polar moment of inertia and c the radius of the shaft. In other words the strength of a shaft varies as the polar section modulus.

3—No.

4—Only in reporting discussions of the Society of Automobile Engineers, particularly in June, 1914.

5—The law of gases and their expansion is the same regardless of volume. The valve timing would be the influential factor in regard to speed.

6—The pressure in any point on the lever you show would be equal to 100 lb. times the distance of A to the fulcrum divided by the distance of the point you wish to consider from the fulcrum.

Voltage Not Measured—Amperage Low

Editor The Automobile:—Will you kindly advise me the approximate voltage and amperage of the primary and secondary circuits in a DU 4 Bosch magneto? E. C. P.

Marysville, Ohio.

—Approximate amperage of the primary at 1000 r.p.m. 7 to 8 and the secondary about 1/10. It is impossible to give you an accurate idea of the voltage in the secondary circuit as this varies through a wide range with the speed.

Leak-Proof Rings Take Up Wear

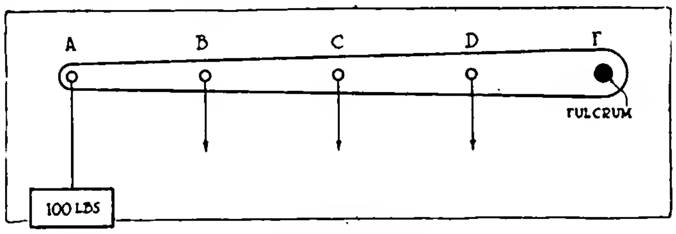
Editor The Automobile:—My engine is worn, I have leak-proof rings. Will these rings, not being fastened in groove, lap in to conform to worn shape of cylinder, or will they shift in groove and retain their perfect circular shape?

Humphreys, Mo. E. H. R.

—If your cylinders are not worn over .005 oversize or out of round the rings should conform very readily and be effective without pinning.

Shorted the Safety Spark Gap

Editor The Automobile:—I am the owner of a model A, E-M-F 30, 1911 automobile. Some mechanic at the repair shop placed a piece of copper wire under the porcelain which supports the copper terminals of the safety gap which is located on the top of the coil box, Splitdorf No. 1745 coil. Not being aware of the above act I tried several times to start the motor, but without success. After considerable trouble and expense I finally located the wire across the terminals short circuiting the safety gap, removed the wire and tried



Principle of leverage

to start motor, but found that I only received a small spark at the plugs. I am writing for information as to what effect on the windings of the coil had the placing of the copper wire across the safety?

2—Would you receive a spark at the plugs with safety short circuited as explained above?

3—What is the object of having this safety? Is it located in the primary or secondary, and how connected? J. B. K.

Kingston, N. Y.

—The shorting of the safety gap by the copper wire would cause no damage to the winding but would prevent the occurrence of the spark at the spark gap of the plug.

2—One terminal of the safety gap is connected to the inner end of the secondary winding and to the grounding terminal of the coil box. The other terminal of the gap is connected to the outer or high tension end of the secondary winding and with the high tension terminal on the box. The object of the safety gap is to protect the winding of the coil when a wire becomes disconnected from a spark plug—the spark in this case jumping at the safety gap instead of at some point inside the winding or within the coil box.

3—Feebleness of spark may be the result of a number of causes. The wiring should be carefully looked over and checked as to its correctness. Loose contacts should be tightened and the contacts within the dash switch should be examined and tested for good contact. Examine the breaker points on the magneto and observe if they open about .025 in. when the engine is cranked. Be sure there is no ground on either leg of the battery. If the cause of the feeble spark is not eliminated by these procedures, the coil with magneto should be examined by a Splitdorf service station.

Putting Vacuum Tank on Fiat

Editor THE AUTOMOBILE:—Kindly advise me how to fit a Stewart vacuum gasoline system on a 15-20 hp. 1911 Italian Fiat, on which the intake manifold is inside the cylinder casting. Also let me know how I may change the oil plate clutch on this car to a dry-plate one, and if this is impossible, please send me names of manufacturers from whom I can purchase a dry-plate clutch for this car.

Menlo Park, Cal. C. H. M.

—Fitting a vacuum system to a Fiat would be rather troublesome, as it would necessitate drilling a hole in the carbureter chamber in the cylinder casting, and this would have to be done in precisely the right spot. It is the kind of job which would be a risky undertaking except if performed by the manufacturers of the engine. You could not get a dry-plate clutch which would fit this car, but you ought not to have trouble with the original clutch, if you use the proper oil and not too much. If you will specify the trouble you are having with the clutch, what oil you use and how much of it, it might be possible for us to help you to obtain the best results from the lubricated clutch.

Fine Spray for Heavy Fuel

Editor, THE AUTOMOBILE:—The use of a hot air intake on a carbureter is a very good idea and so is the use of a hot water jacket around the carbureter. Now why not go still further and make the necessary connections, so that part of the exhaust gases will pass through this same hot water jacket instead of the hot water? This would make the carbureter very much hotter and it would be possible to use very inferior gasoline or even kerosene; or, if this is not practical, how about making a large jacket around the manifold and connecting up this jacket with the exhaust? Has this idea ever been tried out?

In using a mixture of kerosene and gasoline with ordinary carbureter, the engine smokes and carbonizes very badly especially when cold. Would the above idea eliminate this trouble and make it possible to use such a mixture with the idea of reducing the cost of fuel?

Brooklyn, N. Y. E. H.

—Many carbureters have the design to use an exhaust jacket instead of hot water. The principal advantage of the water is that the temperature is more even and there is a slight drawback in the use of exhaust gas, this being that it is liable to throw down sooty deposits so that it is necessary to clean everything out at regular intervals. The chief essentials in using the mixture of kerosene and gasoline are to have a carbureter giving a very fine atomizing spray and to have the intake manifold very warm, it being more important that this should be hot and that the carbureter itself should be so.

Starting Two-Cycle Engine

Editor THE AUTOMOBILE:—I own an American Simplex two-cycle automobile, and although the car is in perfect mechanical condition, I am unable to obtain any service from it because I find it almost impossible to start the motor. In the first place, the compression of this motor is so great that any person of ordinary strength is unable to crank the motor except very slowly. I have overcome this difficulty of fitting the car with a crank giving about twice the leverage obtainable with an ordinary crank. Can you suggest any way to diminish the compression when starting? I have tried cranking with the priming cocks partly open, and even if an explosion is obtained, all the energy escapes through the cocks.

The ignition system comprises a battery and coil, and high tension magneto, and both systems are in perfect condition, and correctly timed. After finally starting, which generally can be accomplished only by towing, the car runs very nicely, developing extraordinary power, showing the carbureter is in proper adjustment. Have you any suggestion to offer that you think will facilitate starting a two-cycle motor? Are all two-cycle motors difficult to start, and if so, what is the reason? After starting, this motor will not run idle without missing, although under load, as I stated above, the motor runs perfectly. Is this a fault common to two-cycle motors?

When shifting from low to second, frequently the gear lever will not slip in unless the clutch is allowed to slightly engage; then the gear slips in and the car proceeds in second gear. Should not the gear slip in with the clutch entirely disengaged, or is this a common occurrence on other cars? I do not have this trouble when shifting from second to high.

I would greatly appreciate any suggestion you have to make, because it seems a pity to scrap this car. If you desire, omit the name of my car when printing this inquiry.

Baltimore, Md. D. M.

—Your difficulty in starting is probably that you cannot get speed enough to compress the charge in the crankcase and get it to transfer into the cylinders without so much condensation occurring that the charge is weakened. It would probably help you if you could arrange to relieve the compression, which could be done by putting a valve in the cylinder about midway of the stroke. Rather careful work would be necessary in fitting the valve, which should be at about midstroke. The object is to have a small valve which is held open by a spring, allowing the first half of the charge to be driven out of the cylinder, so that only the last half is compressed and fired. The valve will close automatically on the firing stroke, but when the engine is started the nut on the top of the stem should be turned so as to bring it down tight on its side.

The difficulty with the clutch may be due to the fact that the clutch stops completely. If it comes entirely to rest the gears on the driving shaft in the transmission will be stationary and it will then be difficult to engage that with the other gears on the shaft which is being driven from the back wheels by the motion of the car. If you have a clutch brake it may be that this is adjusted to be too strong.

ACCESSORIES

H. & N. Carbureter

A FEATURE of this carbureter, which is of the central draft type, is a dashpot balanced annular floating air valve *D*, and integral fuel metering pin *M*, which measures with precision the quantity of gasoline and air required for maximum motor efficiency under all conditions of speed and load. All incoming air travels in a single column, the aim being to produce a perfectly homogeneous mixture, eliminating stratification and loading.

The working vacuum in the chamber *C*, which equalizes the vacuum above and below the dashpot, can be regulated by moving the ball *B* in and out by turning the adjustment screw *S*. Moving the ball in reduces the vacuum in the chamber, allowing the air valve *D* to move up and down more easily and weakening the mixture. Reversing the adjustment, of course, produces the opposite effect. When the correct adjustment has been determined it is fixed by tightening the lock nut *L*.

High Air Velocity

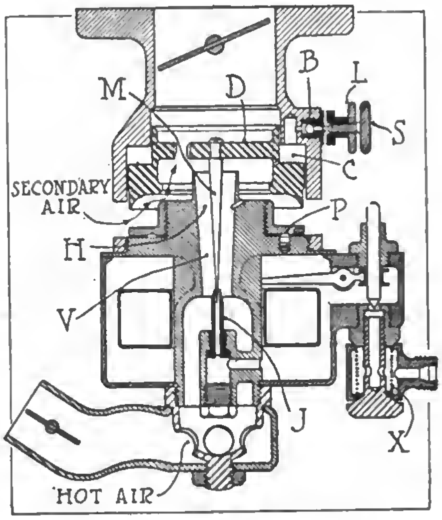
The gasoline jet adjustment is made by turning the threaded ring which forms the base upon which the dashpot rests, raising or lowering the dashpot and with it the metering pin *M*, which varies the jet opening. The ring may be easily turned through a slot. A spring plunger *P* holds the ring in position.

Starting with a cold motor and the present low grade of fuel is facilitated by the extremely high air velocity through the venturi *V*, which has been designed to be scientifically correct. Acceleration is very rapid because of the momentary retarding effect of the variable dashpot on the secondary air intake.

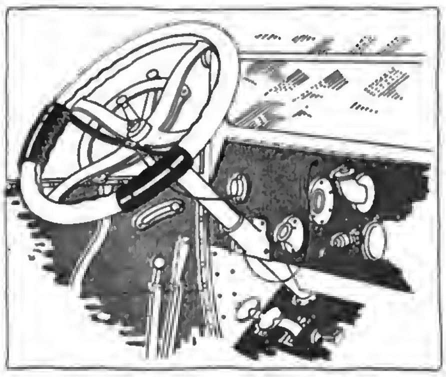
Condensation Prevented

The gasoline enters the float chamber after being strained through the screen *X* and passes through the jet *J* to the venturi where it is mixed with the hot air taken in at the bottom of the carbureter. After leaving the venturi it passes through the mixing chamber, where it is thoroughly mingled with the auxiliary air and passes on to the combustion chamber of the motor. Holes *H* prevent condensation on the walls of the venturi.

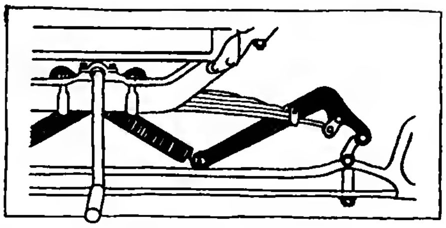
The manufacturers claim that the carbureter produces 1 hp. for every 5 8/10 cu. in. piston displacement in a four-cylinder 4⅛ by 5½ stock motor at 1700 r.p.m. The manufacturer guarantees material and workmanship in the carbureter for one year from the date of purchase and will make repairs or replacements due to defects free of charge if the carbureter is sent prepaid to the factory for inspection. Prices of H. & N. carbureters vary from $12.50 for the ¾-in. size to $100 for the 3-in. size, hot air connections being extra.—H. & N. Carburetor Co., Inc., New York City.



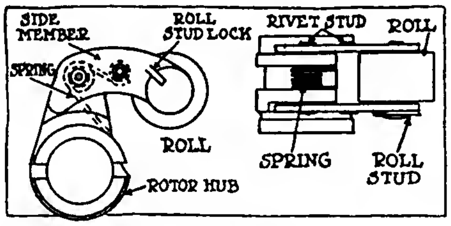
H. & N. central draught carbureter



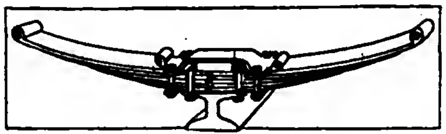
Mounting of Electric Grip Warmers



Dixie shock absorbers for Fords



Rotor of J. & B. Ford timer



Badlat spring clamp for emergencies

Electric Grip Warmer

Two electrically heated grips are laced to the steering wheel rim, one at each side, and these are connected by a cable which runs down the steering column to the storage battery. When installed on Ford cars, they may be connected directly to the magneto. The equipment includes wiring and switch. Price $4.50.—Electric Heating Element Co., Minneapolis.

Dixie Shock Absorbers

This shock absorber is only for Fords and combines a lever and a long coil spring in its construction. The lever is placed between axle and spring end and the load is carried by the long coil spring. Price, $10 per set of four.—Dixie Mfg. Co., Indianapolis, Ind.

J. & B. Timer for Fords

This special timer is interchangeable with the regular Ford timer. The rotor has a cast hub and a jointed arm carrying the contact roller, the latter being pressed outward by a music wire spring of several convolutions. The roller and studs are of hardened and ground steel; the roller stud is locked so that it cannot rotate in the side members of the arm. A feature of the housing is that it has an oil-hole of sufficient size to permit the insertion of the point of the oil-can spout so that oil will not be slopped; the hole is automatically closed against ingress of dirt. The timer sells for $2.—J. &. B. Mfg. Co., Pittsfield, Mass.

Badlat Emergency Spring Clamp

One of these clamps, it is claimed, will fit and repair any broken spring in ten minutes, no matter where the spring is broken, and after it is applied will not break or bend under the heaviest loads or over the roughest roads. The clamp is of forged steel and the wooden block used is of hard maple with leather face and a suction cup at the center of the block, so that it will adhere to the broken spring. The clamp weighs 7 lb., is 12 in. long, ⅛ in. thick and 2 in. wide between the bolt lugs. When the spring is broken off at the shackle bolt one of the eyes at the ends of the clamp will fit the shackle bolt, thus rendering the spring serviceable for an unlimited period. The clamp sells for $3.—James Badlat, Archbald, Pa.

Fuel and the Future

WHATEVER may be the truth as to the necessity for the present price of gasoline, the fact is abundantly clear that the law of supply and demand necessitates a price considerably above that of a few years ago. If the present price is not just it is still obvious that it is merely a matter of time until it becomes just. In other words, the supply of gasoline as originally obtained by very easy methods is lessening.

There are two alternatives. One, which is being developed rapidly, is to find means for making gasoline by processes more elaborate, more troublesome and more costly than the old method of simple distillation. The other is to use heavier oil.

The first procedure offers us ultimately a supply of fuel which may be described as "good gasoline," as this term is usually understood. To establish the necessary cracking plants is going to take time; is going to need expenditure of considerable money; so relief from the present state of affairs cannot come that way quickly, even though its arrival by this road were certain to take place ultimately. There is no doubt about this whatever. There are in existence several cracking processes which enable kerosene to be converted to gasoline. Kerosene today is a drug on the market—it is almost a waste by-product—and commercial common sense will compel its conversion to some useful end.

Meanwhile, however, it is not wise to put off consideration of the direct use of unconverted kerosene in automobile engines. There is no impossibility in a kerosene carbureter, but it will probably be difficult to find a design which will absolutely replace the gasoline type and give exactly the same results. Heat for starting, or some other new function, will be necessary, which means that the automobile user will have some small new thing to learn if he is to utilize kerosene economically.

Hitherto the thing which has acted most against the kerosene carbureter is this very detail: that it cannot be handled *precisely* like a gasoline carbureter. Added to this is the second fact that it is difficult to obtain very slow speeds with the heavier fuel. These things are not serious. To-day the advantage of a much cheaper fuel is sufficient to make it worth while to have a little more elaboration in the carbureter system. The truck, at all events, can be converted easily, for it does not need the same refinement of performance as a high grade touring car.

No Need for Fear

A wide and general use of kerosene has been withheld in the past, largely by reason of the engineer's and manufacturer's fear of putting out anything abnormal. Later developments in automobile engineering have shown that the abnormal is not to be feared as long as it is well tried out before it goes upon the market, and there is absolutely no reason why the same should not be true of the kerosene carbureter.

Electrical equipment has given the careful automobile user, and the majority are fairly careful, a great deal more to keep in proper order. To the necessity for learning to look after something new and strange the average owner has risen capably; why, therefore, should he not do equally well with a kerosene carbureter which would be far less complex than an electrical outfit?

It is sometimes argued that fuel forms so small a proportion of the total cost of running an automobile that a high price does not matter, but this is a short-sighted view. Firstly, it is not true of commercial vehicles, and, secondly, every year sees the other costs of running reduced. Tires cost less than they used to do and will cost still less as weights are reduced and better methods of construction are found. Depreciation grows smaller as prices are lowered, so that a steadily rising fuel price will soon bring the fuel cost up to a position of much greater importance.

Apart from kerosene carbureters, there is another way in which manufacturers can save the ultimate owner of their car a good number of dollars, and this is by making a regular practice of fitting an additional air supply controlled from the steering wheel or steering post. An adequate supply of additional air when used intelligently can increase the miles per gallon nearly 25 per cent on the majority of automobiles. It requires intelligent manipulation of the control, but such handling is not difficult to learn and the accomplishment is very well within the power of any man possessed of normal brain power.

To Cheapen Automobile Fuel

Examination of Sources of Supply Shows Urgency—Need for Improving Cracking Processes and for Kerosene Engines—Problem Not Difficult if Tackled Now

NEW YORK CITY, March 17—The automobile fuel situation was the topic chosen as the subject for the March meeting of the Metropolitan Section Society of Automobile Engineers, held at the Automobile Club of America last night. The importance of the subject drew an audience of about 150 to the meeting, and of these a little over 100 attended an informal dinner given at the club just before the session opened.

The discussion of the experts left no room for doubt that the situation is a serious one, although it also made clear the fact that it is far from desperate. The concluding opinions were that more gasoline would be available by better exploitation of the oil fields, and that, simultaneously, it was highly desirable that automobile engines should be developed and adapted to utilize efficiently a standard kerosene. Kerosene burning seems to be the easiest way to secure a substantial drop in the price of automobile fuel.

E. S. Foljambe presented the paper entitled "The Automobile Fuel Situation," which was in the nature of a review and forecast, with information as to the use of low-grade fuels and suggestions to the automobile industry and the S. A. E. as to the methods best qualified to solve the problem. Among the prominent men who discussed the situation and Mr. Foljambe's paper were Dr. Rittman, inventor of the Rittman cracking process; his associate at the Bureau of Mines, W. A. Williams, who has the title of chief petroleum technologist; Harry Tipper, advertising manager of the Texas Co.; R. H. Johnson of the White Co. and Prof. Charles E. Lucke of Columbia University.

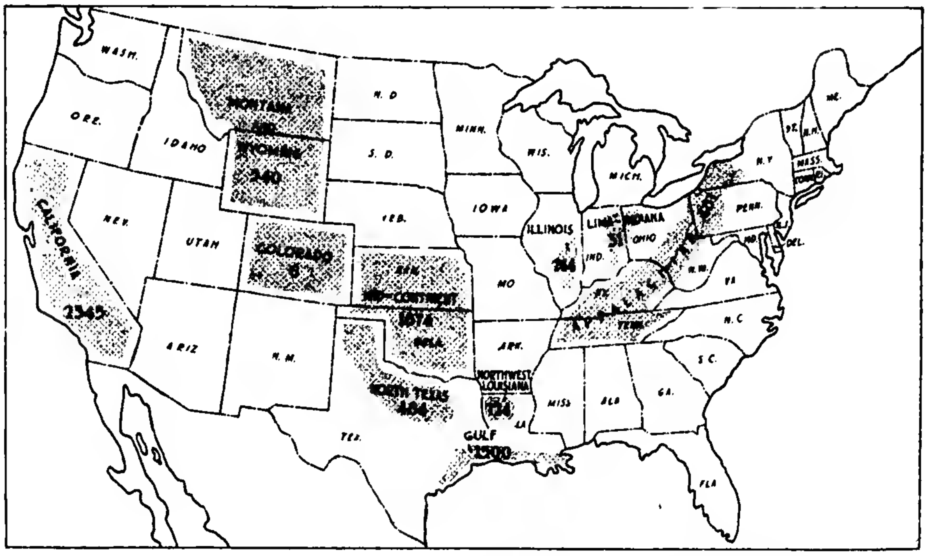
The dinner which preceded the meeting was an informal affair tendered by the Metropolitan Section to Russel Huff, president of the society, and the council. Mr. Huff was the only speaker who was introduced by Leonard Kebler, the chairman of the Metropolitan Section. Mr. Huff spoke a few words of greeting from the Detroit Section of the society and asked the co-operation of the members of the Metropolitan Section in securing a greater enrollment in the S. A. E. for the purpose of furnishing the necessary funds for carrying on the ambitious program which has been entered upon by this year's administration.

Must Use Low-Grade Fuel

The keynote of the evening seemed to be that we are coming rapidly to the point where the low-grade fuels which are now stored or wasted, and in a few cases used for fuel in stationary or similar power plants. must be rendered adaptable to automobiles. Two methods are self-evident to meet this situation, either the present means of vaporization must be so improved as to be able to take care of the lower grade fuels or the fuels themselves must be cracked to form higher grade volatiles.

Mr. Foljambe's paper is a study of existing production, the possibilities of future production and the amount now on hand balanced against present consumption and future consumption if a normal rate of increase in the number of motor vehicles continues. The conclusions he reaches are that we must find better methods of refining the crude in order to produce a larger supply of fuel from the existing supply of crude, that we must create competition in the marketing of fuel products, and furthermore, that vaporizing instruments must be developed which will be capable of using the hydro-carbons of lesser volatility. He turns to the Society of Automobile Engineers as the logical body to solve at least two of the three problems outlined, and states that this situation now ranks in importance to the industry with standardization.

Historically, the paper points out that the first wells were sunk in Pennsylvania in 1859, and subsequently crude oil was used as a medicine and as an illuminant in crude lamps, the oil being used without refining until the time it was discovered that by distillation the products could be separated into high and lower grades of more or less volatility. This distillation led to better illuminating products, but the more volatile liquids were a drug on the market, and for years were turned into the streams until this became a menace to the communities in which the early refineries were located. In 1859 crude sold for $20 per barrel of 42 gal. In 1874 the price of crude had dropped to $3 a barrel. Fluctuations between 1874 and 1914 show the maximum to be $4.23 and the minimum 49 cents.



Showing the distribution of oil in the U. S. A. fields. The figures indicate the comparative amounts remaining to be extracted.

GASOLINE PRODUCED AND EXPORTED IN UNITED STATES

Year	Production, Bbl.	Exported, Bbl.	Difference, Bbl.
1899	6,680,000	297,000	6,383,000
1904	6,920,000	594,000	6,326,000
1909	12,900,000	1,640,000	11,260,000
1914	34,915,000	5,000,000	29,915,000
1915	41,600,000	6,500,000	35,100,000

Mr. Foljambe pointed out that the actual production of oil at the wells is unknown even to the government, and that so-called production is in reality *marketed* production, there being no authentic record from month to month or year to year as to the amount of oil in storage.

The cause for the increase in price of fuel given by Secretary Lane of the Interior, in his report, is divided into six headings, as follows:

1. Increase in consumption of gasoline in the United States during 1915, 25 per cent greater than in 1914 and a similar increase in 1916.
2. Increase in exports, the figures showing the exports of naphtha and lighter products of 1914 to have exceeded those of 1913 by 500,000 barrels, and the exports for 1915 to have exceeded those of 1914 by 1,500,000 barrels. (No government figures are available since these, but the exportation to Europe continues to increase.)
3. The depletion of gasoline stocks, due to increased domestic and export demands. On Jan. 1, 1915, the refiners' storage stock of gasoline amounted to approximately 2,000,000 barrels. Inquiry at this time indicates that there is little or no gasoline now in storage.
4. Decreased production of crude containing a large percentage of gasoline as partially caused by the falling off in output of the Cushing pool, one of the oldest of the modern wells.
5. Increase in the price of crude oil, from which the gasoline is made.
6. Re financial influences: The recent rapid increase in the prices of crude oil and gasoline have been accompanied by rapid increases in the market quotations of oil company shares. The market values of the capital stocks of thirty-eight corporations, of which thirty-five are in the Standard Oil group and three are typical large independent companies, have increased remarkably in the last six months. The stocks of other oil companies probably show a similar rise, but the quotations are not at hand. The thirty-eight companies selected are believed to represent all phases of the oil industry. These rapid increases might be ascribed to the general condition of prosperity and the general upward trend of the stock market but for the fact that during the last quarter of 1915 the oil company stocks did not rise and fall with the market.

Regarding the conservation question, Mr. Foljambe states that it is necessary to have legislation to prevent increased exportations at high prices, to increase the production of the gasoline from the crude by improved methods and to design smaller engines which will be more economical. For immediate relief it is necessary to develop devices to make possible the use of low-grade fuels.

Regarding alcohol, Mr. Foljambe stated that it gives no hope for immediate relief. The reason for this is that even without governmental restrictions for economical use the present type of automobile engine would have to be entirely reconstructed. Instead of using from 65 to 70 lb. compression for efficient alcohol burning, from 150 to 175 lb. compression is necessary. This at once eliminates it as a fuel for the two million vehicles already in use. New engines could be built, however, were it necessary, which would show, on alcohol as a fuel, practically as efficient performance as with gasoline. The horsepower, however, would be less in proportion as the thermal units per pound or less with alcohol than gasoline. Even present types of engines *can* burn alcohol, but they do so very uneconomically, approximately 50 per cent more fuel being required per horsepower hour than were the engine designed for its use. This puts alcohol out of the present reckoning.

Regarding benzol, the author points out that, although it is prevalent in Europe as a fuel, it can only be obtained in this country in limited quantities. Approximately 14,000,000 gal. of benzol were produced in coke ovens in the United States in 1915 with a possible output of 22,000,000 gal. for 1916. This fuel at present sells for 75 cents a gallon and not lower than 65 cents in 1000-gal. lots. It is in great demand for the manufacture of dyes, explosives and carbolic acid. A ton of coal yields 2 gal. of benzol. As long as the war continues benzol is in as great demand as gasoline, and therefore offers no relief, but in the future may well be considered as a possible part of the fuel supply.

Kerosene Holds Good Prospect

Kerosene holds out prospect of immediate relief, as the production of gasoline has caused an immense over-production of kerosene. The latter fluid is being stored at present in vast quantities and means for the disposing of it are being sought by the refiners, who are resorting to marketing it under special trade names. As a matter of fact, even while theoretically burning gasoline, according to Mr. Foljambe, carbureters have recently been provided to handle a mixture of gasoline and kerosene which on the Baume test is often as low as 54 and practically none of it over 60. Commercial kerosene contains 35 per cent of medium and 10 per cent of heavy kerosene.

The paper states that the Rittman process will yield 200 per cent more gasoline than by any other known method, and also states that, although seven plants are in the United States, none of them is producing any appreciable quantity of gasoline.

Kerosene carbureters were next discussed by the author, who showed several types which have been marketed heretofore, and which involved various means for either breaking up the fuel at the jet, completely gasifying it by heat or even in one case igniting it before it entered the cylinder.

In concluding his address Mr. Foljambe drew the deductions that in view of the phenomenal increase in the automobile industry, its accompanying demand for gasoline, together with the increase in the use of tractors, motor boats, farming machinery and stationary engines, and, furthermore, with an exportation many times that of any previous period, something must be done immediately in order to change conditions.

The remedies he suggests are a control of the distribution, and exportation of fuel either by a tax on exports, as now before Congress in the Britten bill, or by some other method not yet devised; also the improvement and general use of more economical distillation processes, and the development of crude oil fields and oil-bearing shales and the natural gas districts.

Hope in Cracking Process

Shale Oil and Other Low Grade Fuels Can Be Commercially Vaporized by This Method According to Bureau of Mines Expert

DR. W. F. RITTMAN of the Bureau of Mines stated that in investigations he had made he had collected samples of gasoline distilled from the crudes in all the different fields. The difference is amazing, and the variation no doubt explains much of the trouble that has been had in vaporization. One company, for instance, sold four different kinds of gasoline. This concern used kerosene as a base and added casing head gasoline to bring it up to the required grade.

Dr. Rittman stated that he had found automobile designers quite willing to design an engine or carbureter to operate on any kind of standardized fuel. He specifically mentioned some experiments that have been carried on in the Bureau lately with the assistance of C. F. Kettering, vice-president of the Dayton Engineering Laboratories Co., covering these points; the Bureau had supplied the chemical information, while Mr. Kettering had worked out the mechanical side.

"America has not unlimited supplies of fuel," continued Dr. Rittman. "Shale oil does not hold great possibilities. It is hard to get it, and in Scotland it has only been possible because of the value of the ammonia also obtained; and now that much of this ammonia is being supplanted by methods for extraction from the atmosphere it is going into further disuse. Benzol and toluol are out of the question."

Cracking Saves 5 Cents a Gallon

Dr. Rittman referred to the cracking process as having been developed by Dr. Burton, and stated that if it were not for these processes gasoline would be selling for 5 cents more per gallon than it does now. He predicted that gasoline would continue to rise until the cracking process or the use of kerosene is able to catch up to the demand. The cracking of crude oil is a reality. Great numbers of intelligent men are now working on the problem, and therefore there can only be one result. There are two sides to the question—one is the chemical and the other is the mechanical—and with both chemists and practical mechanical men on the job at the same time, there can be no doubt the solution will soon be reached.

A graphic description of the cracking process was given by Dr. Rittman, who pictured the molecule of crude, stating that the further down in the vaporization scale we go the larger become the molecules. When there is no restraint on this larger molecule it breaks into smaller molecules of *gas*, but by applying proper restraining influences it can be broken into gasoline instead. The reason he gives for operating his process in the gaseous state is that in this condition it is possible to secure any variations of pressure and temperature. There was a time when crude carried the gasoline price, but to-day gasoline carries the price of crude.

In the Rittman process no heat is applied to the liquid itself in the container. The liquid to be distilled, speaking particularly of petroleum, is contained in the feed tank from whch it is fed into the still. There it is vaporized, and the vapor, not the liquid, is then distilled at a temperature of 550 deg. C. and pressure of 250 lb. per square inch.

The new form of still is, generally speaking, cylindrical in shape, and an inlet tube leads into the still from the container holding the liquid. This tube is equipped with a cock by means of which the flow of the liquid (petroleum) is regulated. In the upper part of the still is placed a number of small iron balls, which are heated to a temperature sufficiently high to vaporize the oil as it flows over them from the inlet tube. The vapor thus formed is forced down into the lower portion of the still by the continual formation of more vapor above.

A series of wires, conveying a powerful electric current, are wound about the lower portion of the cylindrical still with resistance coils, which furnishes the heat for distilling this vapor. The heat can be regulated to any desired temperature. The fact that the expansion of vapor under heat is a definitely known equation, whereas nobody ever knows what a mixture of vapor and liquid is going to do, illustrates the value of the gas factor in the new process. Vaporized oil distilled at the above temperature is then passed into the condensing apparatus.

Regarding the matter of competition, Dr. Rittman said that the little fellow has been forced to put up the price simply because he could not afford to store the crude oil and consequently had to pay for it on a rising scale. He predicted, furthermore, that the price may go to 40 cents or only to 35. Regarding the percentage of gasoline which to-day is made by the cracking process, he stated that it did not exceed 15 per cent and consequently was not enough to offset the rising tendency.

W. A. Williams, chief petroleum technologist of the Bureau of Mines, stated that at the present time we have exhausted about one-third of the visible supply of crude. At the present time, of the products manufactured 20 per cent are being exported, 25 per cent are being burnt under boilers and another 20 per cent sold for cost of production. The better use of the remaining two-thirds is the stepping stone to immediate relief. We are producing now 20,000 bbl. less crude than in 1913 and 40,000 less than in 1915. The 1915 production was particularly rich in gasoline, due to the Cushing pool. There are possibilities in Kansas. Two fields have been discovered which have been very productive, although later drillings show less oil than was indicated in the first borings.

Wastage Now Eliminated

Mr. Williams spoke of Mr. Foljambe's reference to waste, and stated that in some places as much as 50 per cent of the crude oil is left in the sand. This wastage is now being eliminated by the use of water and other methods. The wastes in the Cushing field were eliminated largely by improved drilling which enables the operators to secure the crude practically without waste.

Another interesting reference made by these speakers was the possibility of local fields caring for local demand. For instance, the California situation or that of the Pacific Coast can be taken care of by California production. The necessities of the Rocky Mountain district can be met by the production of the Wyoming and Colorado fields, while the big demand of the Eastern States should be met by the great mid-continent fields which produce 75 per cent of the refinable oils.

Casing-head gas, according to Mr. Williams, will probably never amount to more than 10 per cent of our fuel. Probably the cost of this will go up until the supply catches up to the demand, and this is the case throughout the entire gasoline situation.

Kerosene Vaporizer Easy Problem

No Fundamental Difficulty—Needs Careful Application of Principles—Good Atomization and Correct Air Temperature

PROF. CHARLES E. LUCKE of Columbia University spoke of the practical development of means for using the lower grade fuels. According to him the subject of devices of a mechanical nature to meet the problem have been studied intensively during the past few years, and that while hundreds of schemes had been submitted, there is fundamentally no difficulty, and the final results will not differ much from present types. In fact, he expressed himself as being surprised at the delay in reaching some definite conclusion on the problem and stated that in his belief the difficulties to be overcome are, first, unwillingness to take trouble; second, the patent situation, and third, the problem of making a proper mixture of kerosene and air.

Regarding the first, kerosene as a fuel is fundamentally different from gasoline, and therefore fundamentally different means of vaporizing it must be used. "An engine," he stated, "need not start on the first turn, nor yet on the second or third, as long as a satisfactory start is obtained. It is merely a case of changing from the familiar to the unfamiliar."

In regard to the patent situation, there are thousands of devices of all sorts, of which all are defective. In making the final kerosene carbureter it would possibly be necessary to make element A from one patent, element B from the next, and this, of course, renders the situation complex. The final device must be worked out on proper thermo-chemical lines correctly proportioned.

Professor Lucke states his belief that the problem of making a proper mixture of kerosene and air is not difficult. The engine is a variable speed and variable power machine. It is a multi-cylinder engine, and to make a mixture from a single-header equally distributed under all conditions of weather, temperature and density, may seem quite difficult. Practically, however, it is not insurmountable. Such mixtures can be vaporized. Measured supplies of kerosene and air can be brought together, and by proper heating a dry mixture result. Therefore, the problems consist in arranging a proportioning device and securing the proper temperature. This also is not difficult, for while it is true that the temperature must not be too high or too low the range is not less than 100 deg. Therefore, it is only a question of having first the correct proportion, and secondly, the correct heat supply.

Given these two conditions, the machine will run, but will not perform engine for engine like the power plants of to-day. Car for car, there will be no difference.

An important point brought out by Professor Lucke is the necessity for intimately associated mixtures. An intimate mixture will vaporize at 300 deg. Fahr. readily, while one not so closely intimate under the same conditions will not vaporize at 500 deg. In fact, close to 200 deg. is good enough in some correctly designed headers with proper intermixture. It is simply a question of simple design and of following the laws of vaporization.

Harry Tipper, advertising manager of the Texas Co., stated that in his practical experience he had found plenty of competition in the oil field, and that the market has never agreed. He also stated that the term gasoline was never used by men in the oil business, as it was only a word coined when the more volatile fuels were used for lighting purposes, and never represented a definite cut. Gasoline never meant the same to two companies, while kerosene is a more standardized product. The New York State law requires a definite flash point in an Elliot tester in order that the name kerosene may be used to define the product.

Regarding kerosene, Mr. Tipper said that since it was made when gasoline is made, what can you do with it unless you pay for it with the gasoline? The small refiner suffers and must use the kerosene in order to get rid of it, and he cannot afford to store it.

Fuel Cost Small Percentage

"Do not magnify the part that fuel plays in the cost of running an automobile," said Mr. Tipper. "It is only a small percentage after all. Automobiles were operated successfully in Europe when 35 cents was paid for a gallon of gasoline, and I remember riding in a taxi for 25 cents a mile at that time. Kerosene is the real answer.

R. H. Johnson, president of the New York Dealers' Association, warned against unduly alarming motorists with the predictions of a shortage of fuel in fifteen years. "We do not have to depend on the United States for oil," he said. "Look at the rubber situation, nearly all the crude we use coming from South America. We must remember Mexico, where there are probably the greatest reservoirs in the world, and one well of Mexico has been producing 60,000 bbl. of oil per day for seven years. They have had to cap the wells for lack of facilities for distribution, and several times the production listed in the tabulations in Mr. Foljambe's paper can readily be obtained from the Mexican wells. The Republic of Mexico has enough oil. All it needs is the facility to work the wells."

Dr. Rittman stated that Mexico holds no hope unless it is from the cracking process, but that with this there is room for considerable optimism, since whereas only 5 per cent of the Mexican crude can be refined into gasoline by straight distillation 40 per cent is secured by the cracking process.

Herbert Chase, chief engineer of the Automobile Club of America, suggested that engines may be built on other than the Otto cycle. He pointed out that the Otto cycle is theoretically 35 per cent efficient thermally, whereas in practical motors from 15 to 18 per cent is all that is secured with wide open throttle.

The History of the American Automobile Industry

(*Continued from page* 549)

structures show evidence of much work along these lines. In some cases the air and liquid passed through wicks much as were employed in kerosene lamps. In others, the oil was thrown on several layers of woven wire through which the air was obliged to pass and which wire by its heat absorbed from the flame of combustion quickly vaporized the liquid. The ignition was originally started by applying a torch to a peep hole after a plug had been removed, the plug being quickly inserted thereafter. That the flame might continue from one combustion period to the next a very slight by-pass hole was provided in the inlet valve or near it so that a little fresh air from the air tank continually flowed. This resulted in a little waste of air and fuel during the exhaust stroke, but there would be enough fuel left in the wick or gauze between admissions to burn with this air and keep a small flame alive until the next entrance of air and fuel.

Experience showed that the composite layer of gauzes gave better results if one or more of the wire sheets were perforated so that the air could pass through more freely at the perforated point. This arrangement insured some variety to the mixture, in that it would be more nearly pure air where the perforations were and much more nearly all vapor at the edges of the wire layers where they were held in the cylinder walls and therefore much cooler and more slow in vaporizing the fuel. The result of this arrangement was that it was practically certain a combustible mixture of air and vapor would exist at some point between these extremes and this insured the flame being continuous and the engine certain in operation.

Brayton's engines were frequently built in two-cylinder form and up to 40 hp. Like all engines of that day they were neither high-speed nor lightweight as modern ideas go, but they were really very creditable creations.

In 1873 Brayton arranged with a street car company at Providence, R. I., to apply his engines to one of its cars, but the city authorities refused to allow the car to run on the streets by its own power unless horses were attached to it, so most of the use and testing given the car took place on a short private length of track near a fair ground, after which the experiment was abandoned. In 1876 he licensed Joshua Rose and A. R. Shattuck to make road vehicles driven by his engines.

At Philadelphia a James Fawcett of Pittsburgh, operating bus and hack lines in Pittsburgh, saw the Brayton engine, talked with Brayton and decided to equip an omnibus with this form of power, which was done in 1878. The first form of transmission being a hydraulic one and proving unsatisfactory, the engine was remounted with shaft projecting toward the rear and with bevel gear to drive a cross-shaft. A friction clutch and reversing arrangement were also provided, but like the street car, the project had to be abandoned because the city authorities would not permit its use.

British Prohibit Car Imports

No More Passenger Cars To Be Shipped To the British Isles for the Duration of the War

LONDON, March 21—At a meeting of the Privy Council, King George signed a proclamation prohibiting the importation of automobiles, motorcycles and various other articles. This prohibition has been expected for several weeks, and it is understood that the purpose is mainly in order that shipping may be free to carry necessaries for which the need is urgent. It is in logical sequence to the imposition of the 33 1/3 per cent duty placed upon automobiles by the British government last October. Full information is not yet available, but it is understood that the prohibition does not apply to motor trucks or vehicles to be used solely for commercial purposes.

The immense effect of this decree upon the British industry is difficult to appreciate. It will bear very heavily upon the numerous dealers who have existed for the past year almost entirely by the sale of American automobiles. If the prohibition is maintained for twelve months or more, several of the big London agencies will be forced to close down. It will mean almost complete stagnation in the highly-developed British branches which are maintained by several of the larger American manufacturers.

Regarding the other side of the question, prohibition of imports is bound to have the effect of starving the market, which means that when the ban is removed there will be a tremendous rush to obtain cars, and it will probably be difficult to export them fast enough for months after the imports are made free again.

Four Changes in Timken-David Brown Staff

DETROIT, MICH., March 17—Several promotions are announced by the Timken-David Brown Co., manufacturer of worm-drive axles:

Engineer C. T. Myers is promoted manager of the company.

F. T. Zollinger becomes assistant manager, in charge of purchases, sales, receiving, shipping and accounts.

C. S. Dahlquist becomes general superintendent in charge of manufacturing.

M. Voelk is made general foreman and Mr. Taylor assistant engineer.

United States Rubber Elects E. B. Davis a Director

NEW YORK CITY, March 21—The annual meeting of the stockholders of the United States Rubber Co. was held in New Brunswick, N. J., today. Edgar B. Davis of Brockton, Mass., was elected a director. Mr. Davis is vice-president of the General Rubber Co.

The directorate now consists of eighteen, M. Bun and A. L. Kelley, former directors, having died during the year. The directors are as follows: W. S. Ballou, J. C. Brady, M. F. Brady, M. S. Burrill, S. P. Colt, H. E. Converse, E. B. Davis, James Deshler, J. B. Ford, F. L. Hine, H. L. Hotchkiss, Lester Leland, S. M. Nicholson, R. B. Price, H. E. Sawyer, W. H. Truesdale, T. N. Vail and E. S. Williams.

Saxon Six Price Raised to $815

DETROIT, MICH., March 18—Beginning to-day the Saxon Motor Car Corp.'s six-cylinder roadster and touring car will sell at $815 instead of $785. The reason for the increase in price is stated by officials to be due to the increased expense of manufacturing the car.

Koehler Truck Price Raised to $955

NEWARK, N. J., March 17—On account of the advance in price of materials the H. J. Koehler S. G. Co., this city, has raised the price of its Model K four-cylinder 1-ton truck, complete with body, to $955 and the chassis to $940, f.o.b. Newark. The former price of the chassis was $870.

E. R. Hall Dies Suddenly

MT. CLEMENS, MICH., March 17—E. R. Hall, experimental engineer to the Goodyear Co., died here to-day, having recently come to this city in the hope of recovering from an illness with which he had been afflicted for some time. Mr. Hall was a member of the Council of the Society of Automobile Engineers and a native of Somerville, Mass. Born in 1885, he was educated at the Massachusetts Institute of Technology and joined the Goodyear Rubber Co. on Sept. 1, 1908. His appointment as technical expert for the company was made in February, 1909. Since then the experimental development of Goodyear tires had been in his hands.

Mr. Hall's appointment to be a councillor of the S. A. E. was made in January of this year. He will be deeply regretted by his associates in the Goodyear Co., all of whom held him in the highest esteem.

Nehrbas Heads Premier Production

INDIANAPOLIS, IND., March 18—F. P. Nehrbas has joined the Premier Motor Corp., this city, in the capacity of production manager. Mr. Nehrbas has been in the automobile field since 1910, when he became factory manager of the E. R. Thomas Co. Later he joined the American Locomotive Co., Providence, acting there as works manager.

England May Curtail Gas Supply

Move on Foot to Prohibit use of Automobiles Except for Business Purposes

LONDON, ENGLAND, March 8—Claiming that gasoline must be economized, the British authorities are about to take possession of all stocks and control all sales to the public. Under this scheme the commercial vehicle users, and the army and navy, will have a preferential call, followed by doctors and other professional men. Private motorists will come last.

It is not known exactly how the details of the scheme will be worked out, but it appears probable that gasoline tickets will be issued by magistrates and judges, and that all automobile owners will have to make personal application to these authorities. Each case will be judged on its own merits and it will be decided whether the motorist is eligible for a supply of gasoline, and what quantity shall be allowed him. It is believed that those who have definite business to perform with an automobile will not suffer any great inconvenience, while those car owners who wish to drive for pleasure only will find that such a course is impossible.

In general the scheme is calling forth opposition. It is the opinion among English motorists that there is very little use of automobiles for purely pleasure purposes. The general tightening effect of the war has in itself been sufficient to stop all luxury use of cars. It is also claimed that such a scheme as proposed by the government will be very difficult of application, for it is hard to prove what is justifiable and what unjustifiable motoring. Local magistrates, too, usually possess very little knowledge on motoring matters and will not be competent to estimate the amount of gasoline different types of automobiles should consume for given distances.

This week official posters have been placed on the walls inviting the public to make as little use of automobiles and motorcycles for pleasure purposes as possible.

Walsh Briscoe Advertising Manager

JACKSON, MICH., March 18—R. T. Walsh has been appointed advertising manager of the Briscoe Motor Corp. Mr. Walsh is one of the best known men in the automobile advertising field. For several years he was advertising manager of the Maxwell Motor Co., and previous to this connection he was assistant advertising manager of the Ford Motor Co.

Edmunds & Jones Issue New Stock

$1,000,000 of 7 Per Cent Preferred and 5000 Shares of Common Offered

NEW YORK CITY, March 21—A syndicate of New York bankers is offering $1,000,000 of 7 per cent cumulative preferred and 5000 shares of common stock of the Edmunds & Jones Corp., the new corporation combining the Edmunds & Jones Mfg. Co., the Canadian Lamp & Stamping Co. and the Chicago Electric Mfg. Co. The syndicate, which is headed by White, Weld & Co., Hornblower & Weeks and Merrill, Lynch & Co., offers the 10,000 shares of preferred at 97, two shares of the preferred carrying the privilege of subscribing to one share of common at $30. The authorized issue of the common is 40,000 shares.

It is provided that at least 20 per cent of the surplus profits each year, after the payment of preferred stock dividends, shall be used to acquire and cancel at not more than 120 and accrued dividends the outstanding preferred stock. It is stated that net earnings for 1915 of the three companies are reported in excess of six times the amount required for the preferred stock dividend and combined sales for January and February are reported as more than 100 per cent greater than in the same period of 1915.

The combined balance sheet of the three concerns which make up the Edmunds & Jones Corp. shows that on Jan. 1, 1916, assets totaled $1,315,541.18, made up as follows: cash, $208,075.15; accounts receivable, $264,184.19; merchandise, $339,914.15; real estate, plants machinery, $503,367.69.

Liabilities consisted of current accounts, $114,602.24 on bills payable; preferred stock, $1,000,000 and surplus, represented by 40,000 shares of common stock of no par value but estimated at $200,938.94.

Of the earnings in 1915, those of the Edmunds & Jones Mfg. Co., totaled more than $360,000, and those of the two other concerns amounted at more than $80,000, a total of over $440,000.

Wilson Truck Offers Stock

DETROIT, March 20—The J. C. Wilson Co., which recently increased its capital stock from $20,000 to $225,000, is offering for sale $100,000 of its common stock at a par value of $10 per share. The company makes the Wilson truck and is now preparing for greatly increased production.

The assets of the company total $174,691 and the direct liabilities $42,587, including a mortgage of $25,000. The size of the property owned by the concern is 107 by 588 ft. and partly 142 by 670 ft. The three main factory buildings consist of a three-story structure 51 by 150; a two-story building 90 by 170; another two-story building 33 by 170 ft., and several smaller structures.

Besides making trucks the J. C. Wilson Co. has been a manufacturer of auto tops and has done general trimming since 1908, when the company began operations.

San Francisco Awards Cause Discord

SAN FRANCISCO, CAL., March 15.—That considerable discontent has arisen in connection with the awards in the motor vehicle and accessory department of the transportation exhibit at the recent exposition held here, is apparent from the rumors which have leaked out to the effect that Group Jury 101 which was appointed by the exposition management to specifically make awards in the automobile section of the transportation department, has been discredited in that its findings were materially changed after they were filed with the exposition authorities. It seems that not only have some of the awards made by Group Jury 101 been changed but that additional awards, not included in the regular schedule, have been created. The feeling is gaining headway that the great benefit, which should acrue to any exhibitors in connection with an exhibition of such magnitude, has been very materially reduced because of upsetting the findings of the jury originally selected to make the awards, and also because of the fact that adding additional awards has naturally robbed those primarily intended of much of their intrinsic value.

Want Changes in Ariz. Registration Law

PHOENIX, ARIZ., March 18—In his annual report for 1915, Secretary of State, Sidney P. Osborn emphasizes the necessity for vital changes in the Arizona motor vehicle registration law.

The cost of a license for a car of less than 25 hp., A. L. A. M. rating, is $5, and it is $10 if the engine has greater rated horsepower. Osborn says that this is unfair to the owners of old cars that are worth only a fraction of the prices paid for new models, and recommends that provision be made for a sliding scale of reductions on cars that have been in use over two years.

When the year is half over, half the regular charge for a license good till the first of the following year, is charged. Osborn thinks that a reduction of 25 per cent should be made after the close of the first quarter, and of 75 per cent after the third quarter.

Perlman Secures Two Plants

Perlman Co. Stated to Be Able to Supply All Demands of Industry

NEW YORK CITY, March 21—Following the announcement of the formation of the Perlman Rim Corp. in THE AUTOMOBILE for March 16, comes the statement of L. H. Perlman, president of the new company, that two plants have been secured and are already manufacturing demountable rims and two other factories are under consideration subject to investigation as to the value of the property. Officers of the Perlman company state that the concern is in a position to supply all demands of the car manufacturers, since if present plant facilities are inadequate, in spite of the addition of other factories, contracts will be let to other manufacturers.

In connection with the financial backing of the Perlman company, which is being financed by L. G. Kaufman, president of the Chatham and Phenix National Bank, it is stated that W. C. Durant is interested in the new enterprise.

The Standard Welding Co. has applied to the court to temporarily suspend the injunction until uncompleted orders can be filled, and also is seeking to have the mandate modified. The matter will come up in court on Friday. The company has several demountable rim constructions under consideration and its officials state that if forced to abandon the manufacture of demountable rims, the company's tubing and tube parts business will be greatly augmented.

To Pass on Sale of Bock Bearing Assets

TOLEDO, OHIO, March 18—A special meeting of the stockholders of the Bock Bearing Co. will be held on March 28 at the company's office in West Toledo, for the purpose of considering and taking action upon the proposed sale of the entire property and assets of that company.

Pierce-Arrow Machinists Back at Work

BUFFALO, N. Y., March 21—The plant of the Pierce-Arrow Motor Co., this city, was opened to-day after being closed on March 2, on account of a lockout, following a strike of machinists.

Maxwell Owners Offer Cars to Army

EL PASO, TEX., March 18—Owners of 140 Maxwells, living in and around El Paso, have offered their services and cars to General Pershing of the U. S. Army, for use as he sees fit in any movement of troops. The owners have all signed an agreement to place their cars at the disposal of the army.

S. A. E. Standards Meeting April 21

Cleveland Chosen as Meeting Place—Standards, Council and Section Meetings

New York City, March 18—At the meeting of the Council of the Society of Automobile Engineers held this week it was decided that the next general meeting of the Standards Committee should take place in Cleveland on April 21. It is laid down in the rules that the two meetings of the Standards Committee, which take place between the general meetings of the Society, shall be held on the second Thursday in April, and the second Thursday in October. Seeing that the Cleveland section has an important paper on carbureters by F. O. Ball scheduled for Friday, April 21, the Council thought it advisable to alter the date of the Standards Committee meeting so that a two-day session could include standardization work, the council meeting ing and the Cleveland section paper.

On April 20 three or four of the standards divisions will meet in Cleveland and the council will meet in the afternoon. It is expected that the whole of April 21 will be devoted to the discussion of standardization work, and a prominent subject will be further consideration of automobile lighting with particular reference to glare.

It is expected that practically all the divisions of the Standards Committee will hold meetings previous to the general meeting and the general meeting of the committee will have to consider a number of important matters. The nomenclature work is progressing very rapidly, and it is hoped to have this completed and ready for submission to the society at the summer meeting on board the Noronic.

A tabulation is at present being made showing the very extensive use of S. A. E. standards by automobile manufacturers and, although this is not completed, results to date show that acceptance of the more important standards is almost universal.

J. H. Utz, chairman of the Miscellaneous division, is arranging many of the details of the Cleveland meeting, and it is anticipated that the attendance will be very large.

Electric Storage Battery Has Gross Sales of $1,770,188

Philadelphia, Pa., March 18—The Electric Storage Battery Co., this city, for the year ended Dec. 31, 1915, had gross sales of $1,770,188, as compared with $1,395,793 in 1914. The 1915 income, amounting to $1,360,748, was equal to 8.37 per cent on $16,249,425 capital stock, compared with $1,103,237 in 1914, which was equal to 6.78 per cent on $16,250,000 stock. The surplus, after dividends, was $710,784, compared with $453,273 in 1914. The balance sheet showed $653,756 cash on hand and a reserve of $1,081,201.

The retiring directors were re-elected at the annual meeting in Camden, N. J. The board will meet for organization on Wednesday, April 5.

25,000 Cadillac Eights Shipped

Detroit, Mich., March 22—On March 16 the Cadillac Motor Car Co. shipped 25,000 Cadillac eights. This quantity has been produced since the company commenced manufacturing this model, October, 1914. They state that the twenty-five thousandth car would have been shipped earlier had more freight cars been available.

Overland Shipments Total 27,685 in First Two Months

Toledo, Ohio, March 18—Shipments of Overland and Willys Knight cars for the first two months of 1916, totaled 27,685 as against 10,240 for the corresponding months of 1915. During January, 1916, 12,393 cars left the factory, as compared with 4613 for the same month of 1915. During the whole month of February, 1915, 5627 Overland cars were shipped, while this year, this total was exceeded by 500 at the 18th of the month.

Fiat Patent Case Settled

New York City, March 21—The suit of the Fiat Co. against the Olds Motor Works, charging infringement of design patent No. 48,219, covering a radiator and hood design, has been settled out of court by the payment of back damages and the agreement of the Olds company to discontinue the manufacture of the design in question. The patent in the suit, wihch was in the U. S. district court for the southern district of New York, was issued Nov. 30, 1915, to Carlo Cavalli, Turin, Italy, who assigned it to the Fiat concern.

Bull Resigns as Cole Assistant Engineer

Indianapolis, Ind., March 16—A. A. Bull has resigned as assistant chief engineer of the Cole Motor Car Co., this city. Up to the present time he has made no other connection.

Morgan & Wright Enlarge

Detroit, March 18—The plant of Morgan & Wright, the automobile tire makers, was recently enlarged by two stories, giving the plant 45,000 additional square feet of floor space.

At present 3000 men are employed, but the force is to be gradually increased to 4000 or more. Production is also to be increased to 10,000 tires daily.

S.A.E. Summer Trip Details

Officials Appointed to Take Charge of Various Activities—June 12 Busy Day

Detroit, March 17.—Official headquarters for the Society of Automobile Engineers, previous to sailing from Detroit on its annual summer cruise, June 12-16, have been arranged for at Hotel Ponchartrain at this city. R. O. Gill, in charge of hotel arrangements has contracted for the ball room floor for Monday June 12. Up to sailing time of the Noronic at 2 p. m. all business of the S. A. E. will be transacted in this headquarters. A complete staff of officials to care for every need of S. A. E. members reaching the city on the morning trains will be on hand. Plans have been evolved for a committee in charge of W. B. Stout to care for all baggage of members sailing. A members' luncheon will be served in the ball room and each of the six S. A. E. sections will maintain headquarters in the ball room previous to sailing.

The volume of work incidental to handling a summer cruise of 550 engineers on the Great Lakes is nearly as large as staging a national convention to nominate a presidential candidate. The 1916 meetings committee, which has entire charge of this work, has nearly completed its organization to handle the various work, and its organization follows:

Purser and accounts—S. B. Dusibberre.

Transportation and baggage—W. B. Stout.

Hotel headquarters—R. O. Gill.

Papers for summer session—K. W. Zimmerschied.

Daily S. A. E. on boat—D. Beecroft.

Automobiles for factory visits—J. G. Vincent.

Badges and Souvenirs—K. W. Zimmerschied.

Wireless service—W. A. Brush.

Music and entertainment — C. W. Terry.

Treasurer W. H. Conant has complete charge of tickets and reservations.

S. A. E. members reaching Detroit, Monday morning, June 12, will have an opportunity of visiting the different motor car and other factories. Cars will be at the hotel at the convenience of members for this purpose. Other cars will be furnished for sight-seeing parties of ladies.

—J. D. Kaufman, who for the past several years has been sales representative for the American Die & Tool Co., Reading, Pa., has been appointed sales manager of that company.

Chicago Amateur Race Popular

Many Sportsmen Arrive for Practice on Chicago Speedway—Some Fast Laps Made

CHICAGO, March 20—That there will be a large entry list for the interclub professional drivers' race at the Chicago speedway, May 20, seems to be indicated by the number of amateur enthusiasts that were out for practice with their cars on the board oval yesterday. This was the first regularly observed practice for the unique event, and there were a total of fourteen of the Chicago sportsmen testing the speed possibilities of their mounts. Three weeks ago there was an informal practice staged and on the two days of practice there have been eighteen different cars on the track with amateur pilots at the wheel.

The best time made so far in practice is credited to A. W. Bronstedt, whose Mercer turned a lap in one minute and 36 seconds. This is a speed of 76 miles an hour.

The race as planned is an invitation affair and is open only to amateur drivers who own their cars and are members of some of the leading clubs of Chicago and vicinity. The invitations are extended through the clubs and the cars run under club colors. The mechanic as well must be an amateur and a fellow club member of the driver.

The qualifications committee of the speedway has drawn up the basis for the extending of invitations. According to these supplementary regulations the race will be limited to two, three or four-passenger roadster bodies on roadster chassis, as indicated by the manufacturers' catalog, and motors, while they may be of any piston displacement, providing the bore and stroke is the same as catalogued, and must be of the same general design as cataloged, may be altered as to ignition and carburetion equipment, lightening of piston and connecting rods, changing valve sizes and lifts, changing of timing, lubrication, fuel feed, a full electrical equipment must be carried with the exception of lamps, but may be disconnected electrically and mechanically, so as to take no power.

Corona Grand Prize Expects Twenty Starters

LOS ANGELES, CAL., March 20—The Corona Grand Prize, which the Citrus Belt Racing Association is promoting and which is scheduled for April 8, promises to eclipse all other California speed carnivals and is expected to be the greatest motor meet in the history of the sport in the West.

There will be twenty starters; and many of the drivers claim that all twenty cars will show a speed of 100 miles an hour in the elimination trials, which will be held on the Grand Boulevard the week before the great race. Practically all of the prospective entrants declare that not only will the record established by Eddie Pullen on the Corona course last year be boosted in the speed clash this year, but also that in order to qualify as one of the twenty speediest contestants an entrant will have to pass the century mark in the preliminaries.

The hour for the race has been changed from what it was last year. When the meet was held on Thanksgiving Day the days were so short that it was necessary to begin the race early in the morning in order that visitors would have time to get back to Los Angeles and other southern California points. This year the contest will start at 1:30 o'clock in the afternoon.

There will be one grandstand this year, but it will be large enough to accommodate thousands of people. Instead of having the official stand at the upper end of the course, as heretofore, it will be placed on the lower end near the depot.

In addition to the guaranteed cash prize of $12,000, the Flagler trophy, which is valued at $1,000, will also go to the winner.

Speedway for Birmingham

BIRMINGHAM, ALA., March 18—The Birmingham Motor Speedway Co. to-day awarded a contract for a 2-mile speedway around the lake of the Birmingham Motor and Country Club. The road will cost $500,000. August Herrmann of Cincinnati is president of the speedway company.

Three Duesenbergs for Indianapolis Race

INDIANAPOLIS, IND., March 17—The first three official entries made for the Indianapolis Speedway 300-mile race this year were made by F. S. Duesenberg for three Duesenberg cars, to be driven by O'Donnell, Henderson and D'Alene.

Wilcox Quits Racing to Market Automobiles

INDIANAPOLIS, IND., March 18—Howard Wilcox has announced his retirement from automobile racing. He has entered the automobile dealers' field, with Don Herr, as State distributer of Case and White cars. He has been in the racing field for nearly seven years. Wilcox states that he is going to drive in one more race, but only because he has given his word to do so. The Rotarians in Indianapolis will hold a meeting in the fall, and as an entertainment a special race will be staged on the local speedway.

Wyman & Gordon Reorganized

Capital Now $3,000,000—No Change in Policy—Large Factory Extensions Under Way

WORCESTER, MASS., March 20—The Wyman & Gordon Co., manufacturers of drop forgings for the automobile trade has reorganized with a capial of $3,000,000 and changed its name to Wyman-Gordon Co. This reorganization does not mean any change in the policy of the company, but incorporates new interests represented by Robert F. Herrick, Boston, well known in business and financial circles because of his large investments in varied lines. Due to this reorganization and new capital large factory extensions are under way, these including a separate building housing a heat-treating department. In addition the factory enlargement will accommodate a new inspection department as well as added facilities for testing and laboratory work. A modern administration building is being built. These additions will permit of a large increase in the forge department.

The control and management of the company will continue with those who have been associated with it. The officers are: George F. Fuller, president; H. G. Stoddard, vice-president and treasurer; and Chas. C. Winn, assistant treasurer.

A. P. Warner Enters Trailer Trade

CHICAGO, ILL., March 21—A. P. Warner, founder of the instrument company, has re-entered the automobile industry, becoming head of the Warner Auto Trailer Co., Beloit, Wis., manufacturing commercial trailers and "Twentieth Century" prairie schooner trailers for touring. The Warner company has purchased the old Thomson plant in South Beloit, which has a capacity of 100 trailers a day. Equipment of prairie schooner trailer includes waterproof khaki duck tent, two berths, stove, table, ice chest, etc.

Marmon Increases Price $200

INDIANAPOLIS, IND., March 21—Owing to the increasing cost of material and of labor, The Nordyke & Marmon Co. announces an advance in price on the Marmon models 3 and 4, this advance to be effective immediately. Two hundred dollars has been added to the price of each model, bringing the five-passenger car to $2,900, the seven-passenger car and the three and four-passenger roadster to $2,950.

MUSKEGON, MICH., March 18—The Campbell, Wyant & Cannon Foundry Co., has increased its capital stock from $150,000 to $400,000.

Solid Tire Suit Ends

Court of Appeals Affirms $210,000 Judgment Against Diamond N. Y. Co.

New York City, March 21—The handing down, on Friday last by the Circuit Court of Appeals, sitting in New York City, of a decision against the Diamond Rubber Co. of New York in favor of the Kelly-Springfield Tire Co., and unanimously affirming the decision of the Lower Court, awarding Kelly-Springfield approximately $210,000 damages against the defendant for infringement of the Grant patent, marks the beginning of the end of a patent litigation that has become famous.

This litigation arose over Grant Patent No. 554,675, issued Feb. 18, 1896, to A. W. Grant, for improvement in solid rubber tires. It expired Feb. 18, 1913. This is the patent covering the internal wire Kelly-Springfield solid rubber tire. The litigation has extended over a period of twenty years and the books are full of decisions concerning it. The first suit was decided in December, 1898, in favor of the patent, by the Federal Court in New York City.

In 1901, Judge Wing, in Cincinnati, also found the patent valid; but the Court of Appeals for that Circuit reversed the Lower Court and found the patent void. The Supreme Court refused to take the case on appeal; thus the patent stood valid in the East and void in the Middle West.

In 1906, the question of validity was before the court in Milwaukee, and the patent was there held valid, notwithstanding the decision against it by the Circuit Court of Appeals in Cincinnati. In the same year, the trial court in New York again declared the patent valid and, finally, the Circuit Court of Appeals in New York and in Milwaukee affirmed the decision of the lower courts.

In June, 1907, the Diamond Rubber Co. of New York was sued and the merits of the patent came before the court on ten different occasions in this suit and each time was decided in favor of the patent.

Because of conflicting decisions, the Supreme Court allowed an appeal in the Diamond case, and in 1911 supported the contention of plaintiffs, declared the patent valid and the defendant to infringe. The defendant then refused to pay on the ground that it had made no profits and that plaintiffs had sustained no damages.

The accounting proceeded at great length and the master finally reported that plaintiffs were entitled to 5 cents a pound on all rubber that the defendant had sold.

An application then was made to increase these damages and for the allowance of interest. Judge Hand, sitting in the District Court of New York, allowed $50,000 smart money and $27,000 interest, which, together with costs, resulted in a judgment against the defendant for approximately $210,000.

In the meantime, numerous other alleged infringers have been prosecuted and several suits are now pending in the accounting stage. In one against the Republic Rubber Co., Youngstown, Ohio, the Master has awarded the plaintiffs $115,000, being at the rate of 5 cents a pound; and also in a case against the Goodrich company an award has been made on the same basis, amounting to $262,000 in favor of the Kelly-Springfield company.

The decision just handed down is particularly important to patentees, as it firmly establishes a new measure of damages in this class of cases; or, rather, firmly establishes an old measure of damages that had been hesitatingly advanced and had practically been discarded.

Formerly, a successful plaintiff in a patent case was limited either to the profits made by defendant or to such damages as could be distinctly shown, measured by license fees, loss of sales or forced diminution of price.

The measure of damages invoked by plaintiffs in the Diamond case was that a uniform license fee had been established; and also that they were entitled to recover what was reasonable as a royalty.

Waite Tractor Moves to Elgin

Elgin, Ill., March 18—The Waite Tractor Co., late of Chicago, has removed to Elgin, Ill., and has commenced operations in the Magnus Building, River and Kimball Streets. The Elgin Commercial Club has given the company a bonus of $1,000 and rent free for one year. In the past the company has contracted for the manufacture of its machine, but recently decided to establish a plant of its own and manufacture its product itself. The tractor can develop a speed up to 15 m.p.h., and can be utilized for farm machinery power as well as field or road work. Twenty-five men will be employed at the outset, and machinery is now being installed.

Quality T. & R. Co. to Change Name

Hartville, Ohio, March 20—At a meeting of the stockholders of the Quality Tire & Rubber Co., this city, April 8, the name of the firm will be changed to Besaw Tire & Rubber Co. The new name is given for C. A. Besaw, president. C. A. Besaw, J. C. Harmony, F. E. Schumacher, Hiram Carper, G. E. Munk, Oliver Brumbaugh and M. J. Herr are directors.

Approve Uniform Service

A.S.M.A.M. Think Manufacturers Should Adopt Standard Service Plan

Detroit, March 18—Not only are the members of the Automobile Service Managers' Association of Michigan in favor of the adoption by the manufacturers of a uniform or standard service plan, but local automobile distributors and dealers approve the idea and are hoping that an understanding will soon be reached for the adoption of such a plan.

At the meeting held at the Hotel Stattler, March 16, a plan was outlined and approved by those present from the service mangers' association. The matter has been taken up with General Manager Alfred Reeves of the National Automobile Chamber of Commerce, to be taken up by him with the members of the chamber.

Souther Leaves Ferro

Cleveland, Ohio, March 20—Henry Souther, vice-president of the Ferro Machine & Foundry Co., and past president of the Society of Automobile Engineers, has just severed his connection with the Ferro company. Mr. Souther joined Ferro early in 1914, having been consulting engineer to the Standard Roller Bearing Co., Philadelphia, Pa., for the previous four years.

Souther's knowledge of metallurgy is varied and extensive, his business and professional career commencing with the Pennsylvania Steel Co., which he left in 1893 to become engineer for the Pope Mfg. Co., Hartford, Conn. In 1899 he opened an office at Hartford as a consulting engineer, and it was in this capacity that he became prominent in connection with the automobile and allied industries. He was consulting engineer for the Association of Licensed Automobile Manufacturers during the life of that organization and was president of the Society of Automobile Engineers during 1911.

Tractor Show for Northwest

Omaha, Neb., March 22—A tractor-show circuit embracing some seven or eight cities of the best agricultural section of the Northwest has been definitely decided upon, and plans are rapidly nearing completion. The newly-formed circuit will be under the supervision of A. E. Hildebrand of Omaha, whose work will be directed by a committee representing tractor manufacturers.

Nearly 50,000 people attended the tractor show held in Fremont, Neb., last year, and this city will probably be one of the first places selected.

January Exports $8,262,434—Trucks Total $3,416,818—Cars $3,044,995

January, 1915, Total $4,473,865—January, 1916, Shows Gain of Over 84 Per Cent—Exports During Seven Preceding Months Total $66,822,383

WASHINGTON, D. C., March 18—According to statistics compiled by the Department of Commerce, 1269 commercial cars, valued at $3,416,818; 4520 passenger cars, valued at $3,044,995, and $1,800,621 in parts, not including engines and tires, were exported in January last. During the seven months ended January, 1916, the exports amounted to 12,391 commercial cars, valued at $32,559,354; passenger cars to the number of 27,376, the value of which was $21,471,078, and parts, not including engines and tires, to the value of $12,791,951.

During the corresponding periods of last year the exports were as follows: January, 1915: Commercial cars, 935, valued at $2,545,527; passenger cars, 1803, valued at $1,313,153; parts, not including engines and tires, $615,185. Seven months ended January, 1915: Commercial cars, 3972, valued at $10,989,442; passenger cars, 6904, valued at $5,808,099; parts, not including engines and tires, $2,789,246.

The United Kingdom's purchases of cars in January last numbered 1090 machines, valued at $1,718,886, while during the seven months' period the number was 13,571 machines, valued at $18,614,667. In January a year ago 1389 cars were shipped there, the value of which was $1,770,966, while during the seven months ended January, 1915, the number was 3448 and the value $4,758,702.

Shipments to France in January last amounted to 521 cars, valued at $1,358,115, while during the seven months' period the number was 3172 and the value $7,993,295. During January a year ago 236 cars were shipped to France, the value of which was $527,869, while during the seven months' period the number was 2024 and the value $5,017,488.

There were no exports of cars to Germany either in January last or during the seven months' period of this year. None was shipped in January a year ago, while during the seven months' period of that year sixteen cars, valued at $17,364, were exported to the Kaiser's land.

Russian Figures Large

One hundred and fifty-one cars were exported to Russia in January last, the value being $338,324, while during the seven months' period the number was 3261 and the value $12,824,047. There are no statistics available for the corresponding periods of last year.

Denmark is another European country that is now figuring in our automobile export trade, 105 machines, valued at $80,687, being shipped there in January last, while during the seven months' period the number was 442 and the value $269,437.

Italy bought nineteen American cars in January last, the value being $24,173. During the seven months' period the number was 184 and the value $127,586. Only three cars were shipped to Italy during January a year ago, the value being $2,412. During the seven months' period the number was twenty-six and the value $23,722.

The shipments to "all other European countries" amounted to 116 cars, valued at $100,372, in January last, and to 659 cars, valued at $673,928, during the seven months' period. For the corresponding periods of last year the number was 130 cars, valued at $229,065, in January, and during the seven months the number was 701 cars, valued at $1,894,278.

Increase in Canadian Imports

During January last 862 cars, valued at $581,563, were exported to Canada, while during the seven months' period the number exported was 3340, valued at $2,440,316. This is a big increase over the shipments for the same periods of last year, when 263 cars, valued at $226,533, were shipped in January, while for the seven months' period the number was 1378 and the value $1,890,693.

The number of cars shipped to Mexico in January last was thirty-nine, valued at $42,154, as against three, valued at $1,410, exported there in January a year ago. During the seven months' period the number increased from thirty-nine, valued at $48,427, in 1915, to 169, valued at $168,316, in 1916.

The West Indies and Bermuda continue to loom up large in the export tables, 266 cars, valued at $187,339, being shipped there in January last, as against 102 cars, valued at $66,980, exported in January a year ago. During the seven months' period the shipments increased from 468 cars, valued at $341,012, in 1915, to 2170 cars, valued at $1,345,896, in 1915.

Heretofore shipments of cars to South American countries have been grouped under the general head South America. In January a year ago the number of cars exported there was 104, valued at $54,276, while during the seven months' period the number was 471, valued at $270,685. The growing importance of this trade is seen in the following fig-

Exports of Automobiles, Trucks and Parts for January and Seven Previous Months

	January				Seven months ending January			
	1915		1916		1915		1916	
	Number	Value	Number	Value	Number	Value	Number	Value

ures: Argentina, 576 cars, valued at $245,376, in January last, and 2555 cars, valued at $985,535, during the seven months' period; Brazil, twenty-four cars, valued at $15,069, in January, and 110 cars, valued at $66,056, during the seven months; Chile, sixty-nine cars, valued at $40,935, in January, and 486 cars, valued at $338,094, during the seven months; Venezuela, thirty cars, valued at $18,452, in January, and 277 cars, valued at $184,175, during the seven months; other South American countries, forty-four cars, valued at $25,290, in January, and 254 cars, valued at $146,834, during the seven months.

British East Indies took 399 cars, valued at $286,872, during January last, and 1629 cars, valued at $1,230,243, during the seven months' period. Shipments to British Oceania during January last amounted to 576 cars, valued at $441,306, while during the seven months' period the number was 3407, valued at $2,806,256. During these same periods the shipments to other Asia and Oceania numbered 551 cars, valued at $685,391, in January, and 1727 cars, valued at $2,370,204, during the seven months.

Shipments to all other countries amounted to 351 cars, valued at $271,509, in January, and to 2354 cars, valued at $1,418,547, during the seven months' period.

The table opposite shows the exports in detail.

Shuler Axle Incorporated

DETROIT, March 16—The Shuler Axle Mfg. Co. has been incorporated, with a capital stock of $100,000, to make automobile axles. Temporary manufacturing quarters have been secured in the premises of the West Side Fuel & Supply Co., Dragoon Avenue and the Wabash Railroad.

Frank A. Shuler, who is president and general manager of the new concern, started with the Timken-Detroit Axle Co. several years ago. Later he joined the Metal Products Co., became production superintendent, and after four years again joined the Timken organization, becoming master mechanic and assistant superintendent.

The other incorporators and officials of the new company are J. J. Kern, secretary-treasurer, and who is connected with the West Side Fuel & Supply Co., and R. H. Dewey, who is vice-president.

Butler Co. to Move to Indianapolis

KNIGHTSTOWN, IND., March 17—To better its shipping facilities and service the Butler Mfg. Co., this city, will move its plant to Indianapolis. This company will devote its time to the manufacture of three types of pistons, cylinder regrinding and special machine-shop work.

Freight Car Situation Still Serious

Detroit Manufacturers See Need for Use of Convertible Flats for Months Ahead

DETROIT, March 20—With hardly any exception local automobile manufacturers say that the railroad freight car situation is no better to-day than what it was a month ago. Several traffic department officials claim that it is even worse, while a few others say there has been a slight improvement.

All who were seen on the subject agree that the railroads are trying their best to remedy the conditions, but that the roads are practically powerless to overcome conditions which they do not and cannot control.

In the first place there is the weather. There have been so many storms in the East this winter, and when a road had partially cleared its tracks and started to move its long line of waiting freight cars, a new storm, more violent than the preceding one, again tied up the whole system.

Cars Tied Up in East

The second reason why there is so little relief is the fact that thousands of cars loaded with freight are tied up, in the East, and cannot be released. This applies to almost all the roads to New York and New England.

It is not alone the automobile industry which is greatly hampered in the moving of its products. The condition is general in all industries. The railroads receive as many complaints from steel manufacturers, from ammunition makers, from furniture makers, etc., as from automobile manufacturers.

One of the big railroad freight traffic managers stated that no one is to blame because no one, either manufacturer or railroad, has foreseen that such a condition would arise. Had the roads been advised by the automobile manufacturers that their production will be double in 1916, then they would not have hesitated to take steps for additional automobile equipment. As it is the manufacturers, with a few exceptions, have not and do not post the railroads.

Cannot Get New Cars

The Michigan Central railroad ordered 4500 special 40-ft. automobile freight cars in September. Up to date only about 225 have been delivered. The delay is caused owing to the shortage of material.

The Packard and Chalmers companies say that there has been practically no improvement in the freight car situation. Both concerns had to put on about seventy-five extra men who are used in making improvised boxes, or wooden coverings, over the automobiles when the latter are on the flat cars. Dodge Brothers say they are short at least 40 per cent of the number of railroad cars they need daily. The Hupp Company cannot get enough flat cars and these come in irregularly and in very small number. Cadillac finds conditions somewhat better as far as shipping West is concerned, but no improvement in the East. Paige-Detroit says the conditions are a little better. Studebaker has found hardly any betterment. All of these concerns had to put on extra help either in making wooden housings on the flat cars or to take care of other special work which, under normal conditions, would not be necessary, which means a big additional expense in shipping, but they are content to get whatever cars they can.

The Detroit Board of Commerce has decided to open a special freight traffic school, under the direction of Traffic Commissioner Arthur T. Waterfall, from March 21 to May 23.

Traffic and operating officials from the different railroads will, from time to time, be present at the lessons, and will explain various different subjects, concerning their respective departments.

That the school is expected to bring about good results and that it will be well attended is the opinion of Mr. Waterfall.

Studebaker Boosts Output

DETROIT, March 20—Additions to the Studebaker Corp. plant here, involving an expenditure of $1,000,000 for buildings and equipment, are now practically completed. It means that production will soon be increased to at least 400 cars a day, instead of 300 as now, and that this year's output will probably be 100,000 cars.

Extensions to the plant consist of a new building for the manufacturing of heavy forgings, such as six-throw crank shafts and front axles; a three-story warehouse, 52 by 335 ft., with accommodations for 150 carloads of raw material; a three-story addition to the main manufacturing plant, adding 35,000 sq. ft., of floor space, to be used for wheel, chassis, painting and assembly; seven large double chambered furnaces to replace smaller types in the heat treating and carbonizing departments; seven forging machines for making gear blanks are being added, also two additional 500-hp. water tube boilers; a 2000-hp. low pressure turbine generator is being added to be operated by exhaust steam available from the forge plant. In the manufacturing machinery department seventy-five pieces of equipment are also being added to take care of six-cylinder engine parts.

Detroit Section of the S. A. E. Discusses Rear Axle Design

J. G. Perrin's Paper Provokes Lively Discussion—Transmission Brakes and Truck Axles Without Differentials Are Leading Subjects

DETROIT, MICH., March 17—Before the usual large crowd that overflowed the convention hall of the Pontchartrain Hotel, J. G. Perrin, chief engineer, Timken-Detroit Axle Co., read a paper on the Evolution of the Rear Axle, and provoked a spirited discussion of a topic that is of utmost importance to-day. Much interest was displayed in the hints that before long we may have cars without differentials, as experiments are now being conducted along this line.

Previous to the reading of the paper of the evening, a constitution, by-laws and rules were adopted by the Detroit Section. The offering of these for adoption was the occasion of a rather spirited discussion in some quarters.

Up to this time the Section has operated with no constitution and by-laws other than those of the national S. A. E., and the action simply puts the Section upon a firmer business basis.

Perrin's paper began with an historical sketch of rear axle development and considered some of the more prominent constructions of the day. Mostly it will be valuable for purposes of record and is a useful reference for engineers who are contemplating the design of a new axle. Toward the end the following statement was made regarding materials suitable for use in rear axle construction.

Materials Use in Rear Axles

Malleable iron is used in differential housings in the carrier units that hold the pinion-shaft and differential bearings, brake spiders and some of the hubs. This material has the following average physical properties:

Maximum strength	43,790 lb. per sq. in.
Elastic limit	30,540 lb. per sq. in.

Drive-shafts are made from chrome nickel steel with these physical properties.

Maximum strength	145,000 lb. per sq. in.
Elastic limit	120,000 lb. per sq. in.
Elongation in 2 in.	15 per cent
Reduction in area	52 per cent

This material in a shaft of 1 5/16-in. diameter, the size used in large production, when subjected to torsion shows the following ability:

Torsional moment

Maximum strength	54,000 lb.-in.
Elastic limit	33,000 lb.-in.
Angle of twist	1,300 deg.
Fiber stress	74,600 lb. per sq. in.

The sleeve used in the full-floating type of axle is made of either carbon or chrome nickel steel, according to the size and load capacity of axle. The chrome nickel steel shows the following physical properties:

Maximum strength	105,500 lb. per sq. in.
Elastic limit	81,000 lb. per sq. in.
Elongation in 2 in.	25 per cent
Reduction in area	66 per cent

The bevel gear and pinion have to be of a steel of high physical properties with a hard wearing surface and tough inner core. This necessitates the use of a case-hardening low-carbon steel alloyed with chromium and nickel. The core shows the following average physical properties:

Maximum strength	107,000 lb. per sq. in.
Elastic limit	60,000 lb. per sq. in.

Everybody who has had the experience in testing case hardened specimens, knows that it is very difficult to get uniform tests. We know that we get certain results, but the physical tests of case hardened pieces generally are very unsatisfactory, and they vary a great deal, so that we have to judge of the results we are getting by other than the actual physical tests of the case hardened specimens.

Discussion Lively

Chairman George W. Dunham, in opening the discussion, called attention to the great variety of stresses to which the rear axle is subjected, and said that after analyzing them you wonder that the unit stands up at all. It carries the torque, transmits the power, and also has to do the work of propelling the vehicle, which is in another direction, and is subject to side strains as the car skids or drops into ruts or sudden obstructions. And it is doing its work right down in the dirt and mud all the time. A great many axles to-day, he commented, are still subject to oil leakage trouble.

McCall White Expects Development

D. McCall White, Engineer for the Cadillac Company, read a very interesting commentary on the paper. It is given in part below:

We have to-day reached great heights of development in engine design, and I think that now is the time for engineers to turn their fertile brains to the development, and further refinements in other portions of the chassis, notable among which is the rear axle.

Mr. Perrin has mentioned that the stamped steel type of axle is probably the most universally used type of any form of axle construction, as regards number of car makers who have adopted it.

I would like to ask Mr. Perrin, if the reason for the almost wholesale adoption of this type is not rather, because of the quantities which are being turned out by his company, than the fact that it is the best type of axle design having the maximum strength for the minimum weight.

The banjo casing or pressed steel housing is, as Mr. Perrin describes, made from carbon steel which has an elastic limit of 34,000 lb. per square inch, and therefore, cannot be stressed above 7000 lb. per square inch without disastrous effect.

The approximate greatest stress in a floating axle is near the spring seat, and is caused by the combined cantilever loads from the weight of the car, the tractive effort, and torque reaction.

The diameter of the casing here cannot be very great, so the tubular portion of the casing must either be somewhat thick to withstand the stress or an inserted tube made from alloy steel must be used.

This inner alloy steel tube must in its turn be carried in, and adequately supported, towards the center of the casing, so that we really have a comparatively heavy construction.

British Design

This particular design of the banjo casing originated, if I remember correctly, in England, at the plant of the Daimler Motor Car Company, around the year 1905-1906, and has since, as Mr. Perrin states, been largely used in this country.

In view of the large size of that part of the casing which surrounds the bevel gears, the stress is extremely low, with the result that a thin casing could reasonably be employed were it not for the fact that it would not be a manufacturing possibility to weld the halves of the casing together satisfactorily, if they were less in thickness than about 5/32 in.

This then, forces us to arrive at the fact that, were the axle scientifically designed, without manufacturing prohibitions, we could have a pressing of varying thickness made from alloy steel to suit the moduli of the sections employed, and the stresses which come upon those sections.

The different forces which rear axles require to resist are of a most complex form, varying from minimum to maximum with the greatest frequency, and it behooves us, in view of the fact that this part is unsprung weight, to exert as much ingenuity as we possibly can, to make this important assembly as light as possible, combined with rigidity.

Engineers who have been seeking the greatest reduction of weight in rear axle design, are, I think, rather inclined towards swaged alloy steel tubings, flanged and bolted to an aluminum center piece or differential casing.

It is a matter of considerable doubt as to whether an axle designed on those lines will be able to withstand the continuous vibrations, caused by the pounding on rough roads even though it be supported by a tie rod of sufficient strength, although, I understand that one prominent manufacturing company originally used an aluminum center piece with success, and upon the price of the commodity going beyond the reach of its purse reverted to malleable iron or steel castings, and was confronted with the problem of the axles breaking, due evidently to the increased weight pounding on the rough roads.

On the other hand, I have an authentic statement that another company found that the aluminum center went to pieces due to fatigue after a given mileage, which I understand extended possibly over two years.

It may have been that this latter casing was stressed too highly although history does not say so.

Favors Aluminum Case

Sufficient to say that my experience in Europe leads me to believe that aluminum would be perfectly safe, provided it was not overstressed.

I believe that to-day, considering that we are on the threshold of an era of quieter axles, due to the introduction of spiral bevels, the need of designing a rear axle, the differential of which can be removed almost as easily as a spark plug, is almost gone, more especially as most of us obligingly mount the gasoline tank behind the axle cover, thus making a difficulty of examination in any case, and we could therefore design a stronger and more rigid aluminum casing if such openings were no longer necessary.

I have in past years been an exponent of worm axle design, and still believe that there is some future before it, believing also, from very extended experience, that a slightly lower gear ratio with a worm than with a bevel is necessary in order to compensate for the very slight difference in mechanical efficiency.

Regarding Mr. Perrin's statement about the De Dion Company's axles, I can say that this company still employs the axle with universally jointed shafts, and the differential casing bolted to the frame, to reduce unsprung weight, on their large heavy cars, where the axle would naturally be considerably heavier than in its light cars where the orthodox design is used.

As regards the bevel pinion, I am of opinion that no fewer teeth than eleven should be used if one wishes a sufficiently strong and quiet construction, and with reference to the mounting of same, I am more partial to the overhung pinion than to the pinion supported on both sides, and although this latter would appear to be more correct, the former has given me the quietest rear axle.

Using materials such as Mr. Perrin suggests, the stress, in my opinion should not exceed on the pinion teeth 22,000 lb. per square inch, and on the axle tubes 13,000 lb. per square inch.

Possibly these stresses may seem high, but one must remember that there are the stresses due to such loads as weight of car, weight of axle itself, reflex engine torque, reflex brake torque, tractive effort, inertia of the axle itself, etc., to be considered.

Brush Dislikes Unsprung Weight

A. P. Brush, Brush Engineering Assn., touched upon the matter of unsprung weight, saying that he is a crank on its elimination as well as in the elimination of other things that prevent the tubes from having only pure torsion.

The possibility of running axles without differentials was dilated upon. Mr. Perrin said that it is being experimented with all over the country. In Europe they are running some of the ambulances without differentials, and they find that the efficiency of the truck is increased a great deal, as regards straight-ahead going. The only limiting factor, so far, has been the short turning radius, as trucks so equipped cannot turn around in such close quarters as conventionally built types, because the friction of the parts is too great. The binding effect in trying to turn around in too short a circle has been too great to be satisfactory on the rough ground. One prominent electrical concern building electric cars, said Mr. Perrin, has tried the non-differential construction out in New York City and found that the ampere draw either with or without differential was practically the same.

F. E. Moskovics, Nordyke & Marmon Co., said that he noticed several concerns are in the habit of making differentials without adjustment, and asked for the comments of the author of the paper on this subject. Mr. Perrin said that the other arrangement that would have to be used, if there were no screw adjustment in the meshing of the bevel gear, is the fitting of variable thicknesses of spacers back of the pinion, back of the main bevel gear. That has been tried, he said, and it is continued to-day in some cases, and while it is perfectly feasible in small productions, it has not proved a commercial possibility in large outputs.

Alex Churchward asked as to the relative efficiency of the spiral bevel, the straight bevel, and worm on passenger car installations, and Mr. Perrin's reply was that neither type has shown enough loss of efficiency to cut any figure. All the figures show that under normal conditions they all run over 95 per cent.

C. C. Hinckley, Engineer Chalmers Company, brought up the questions as to why the grease runs out, why does a brake squeak, etc. Each engineer has a different answer to every question, he said. Hinckley is of the opinion that the biggest development so far in rear axle construction has been the two-pinion differential, believing that it is good for any average practice. He also raised the question as to how to get a big enough ring gear in a car with small wheels, and still have sufficient road clearance.

Regarding this latter point, Mr. Perrin says that you cannot eat your cake and have it too. The thing is a compromise. If you are going to have the power, you must have adequate means of resisting it, and that necessitates teeth of certain sizes. You cannot get away from that, and if you are going to have the ratios, you must have big ring gears. He thought Mr. Hinckley knew as much about brake squeaks as he (Perrin) does.

Cleveland S. A. E. Also Discusses Fuel

CLEVELAND, OHIO, March 18—The meeting of the Cleveland Section of the Society of Automobile Engineers, held here last night, was very successful, the attendance totaling 125, of whom ninety-five dined together immediately before the meeting. Mr. Kettering, the speaker of the evening, did not have a prepared paper, but talked concerning the chemistry of combustion with respect to the major problems of carburetion. Dr. Rittman and Mr. Williams of the Government Bureau of Mines contributed to the discussion, repeating some of the information which they gave the previous evening to the Metropolitan Section. Other speakers were President Russell Huff and general manager C. F. Clarkson.

Settle Details of Columbia Car

DETROIT, March 18—So far have the plans of the Columbia Motors Co., recently organized in Detroit by some prominent men in the industry, among whom are W. E. Metzger and J. G. Bayerline, been completed that a preliminary idea of the type of car thas is to be manufactured is now given out. Built upon a wheelbase of 115 inches, the new Columbia is a six that should claim a position for itself due to its very pleasing outline and general good looks. The ultra-modern type of body design is used in continuing the hood on exactly the same slope as the rest of the body, using a cowl at the back of the front seat, rounding the front of the body over, and slanting the windshield.

The car will be constructed of standard units with the motor, a 3 by 4¾ block-cast six having a multiple dry-disk and three-speed gearset in unit with it. There will be a two-unit starting and lighting system, the name of which is not yet divulged. Other specifications include Tinkem front and three-quarter floating rear axles, cantilever rear springs and semi-elliptic front suspension, chrome-nickel steel frame, and Stewart vacuum feed from a tank at the rear. Some of the equipment features are 32 by 3½ tires on demountable rims, crowned fenders and other features that go with the up-to-date vehicle.

Roominess of the body is made one of the features as well as the general body appearance. The back seat measures 46 in. across, outside of the upholstery. Weight is said to be in the neighborhood of 2150 pounds.

Hupp Addition Nearly Completed

DETROIT, MICH., March 18—Within a few weeks the second of the two stories which are being added to the plant of the Hupp Motor Car Co. here will be completed. It means that nearly 26,000 sq. ft. of additional manufacturing floor space will be added to the plant and that the working force will be increased by several hundred men. Production will be greatly increased.

Silver Has New Sales Plan

NEW YORK, March 17—The C. T. Silver Motor Co., this city, handling Overland, Willys-Knight and Peerless cars, has formed a plan to increase sales by overcoming the present hesitation of buyers on account of the high price of gasoline. This company will furnish gasoline at 25 cents a gallon to retail purchasers from March 20 to Sept. 20. A ticket will be presented to each retail purchaser of a new car entitling him to gasoline at the above price at either of the Silver branches.

Paige Makes Record Order

DETROIT, March 18—On the first day of March the Paige-Detroit Motor Car Co. reports that it had orders on hand for 3748 Paige cars, of a total value of about $4,000,000. Orders from dealers are coming in at such a rate that the Paige company does not believe it will be able to make as many cars as its distributers request. Compared with the business done last year in February, the past month was several hundred per cent better.

M. & S. Capital Now $1,750,000

Increased $750,000—Amount All Subscribed for by Stockholders

DETROIT, MICH., March 18—The capital stock of the M. & S. Gear Co., manufacturer of the M. & S. differentials, has been increased from $1,000,000 to $1,750,000 and the issue of $250,000 of preferred stock was authorized. This amount was all subscribed for by the stockholders.

The following officers have been elected: Lewis H. Scurlock, continuing as president and general manager; W. H. Kirn and Wm. H. Hill, vice-presidents; W. H. Holden, secretary and treasurer; and C. C. Wolf, Parkersburg, Ia., and O. W. Smith, New York City, directors.

The M. & S. company is now manufacturing its new design which is an improvement over that previously used in that it does not employ a spider for holding the gears. These improvements have greatly reduced the cost of manufacture.

The business of the company has greatly increased during the last six months, and steps were taken some time ago for increasing the output. The Detroit plant on Lycaste Street has been in course of enlargement and will be ready by June 1, when the daily production here will average 200 differentials or more. Officials say that orders on the books now will keep the plant running to its full capacity for many months.

Steel Reaches Record Prices

NEW YORK CITY, March 21—A continuation this week of record-breaking prices in the steel market has been the cause of many inquiries as to how high the market will go. Prices now on Bessemer and open-hearth steel are double those of 1914. Last week both grades of steel jumped $5 per ton to $45. Another metal which is quoting now high, is lead. Prices on this metal are now at double what they were a year ago. This week lead jumped to $8 per 100 lb., the highest it has reached. Beams and channels rose to $2.62 per 100 lb. at a gain of 20 cents.

Pennsylvania crude oil supplemented the rise of the metals by going up to $2.60 a barrel. This high price has been equalled only once before, that being in 1895, when it was maintained for only 24 hr. On that occasion it reacted to $2.40, but there is no such movement in prospect now, according to leading oil interests. Failure of repeated advances through the last several months to increase the supplies of crude available for refiners is given as the cause for the advance. Refiners, however, expect to replenish their tanks, from the oil held in storage, and which they felt was being held by producers for $2.50. They now feel that little short of $3 a barrel will move this reserve.

There was no material change in the rubber situation last week, though trading was a little more active. Prices held steady with Ceylon first latex, a little lower. Para rubber went down to 74 cents a pound on Thursday, but picked up gradually again to 76 cents.

Daily Market Reports for the Past Week

Material	Tues.	Wed.	Thur.	Fri.	Sat.	Mon.	Week's Ch'ge

Detroit Axle Capital Stock Increased to $150,000

DETROIT, MICH., March 18—The capital stock of the Detroit Axle Co. has been increased from $50,000 to $150,000. This concern, which started here only a few years ago, has been growing steadily. Its business thus far this year has been several hundred per cent better than last year's.

Jacobson Machine Gets Saxon Order

WARREN, PA., March 17—The Jacobson Machine Mfg. Co., this city, has received a half-million-dollar order from the Saxon Motor Co., Detroit. It is for 7500 rear axles and transmission gears.

Another Overland Building for St. Paul

ST. PAUL, MINN., March 17—A new $700,000 plant is to be erected in St. Paul by the Willys-Overland Co. It will be built west of the Overland assembling plant at Eustis Street and University Avenue, in the Midway district.

The present building is being used to capacity. The structure which will be duplicated has ground dimensions of 200 x 500 ft., and is four stories.

J. I. Case Earnings Larger

RACINE, WIS., March 18—The annual report of the J. I. Case T. M. Co., Racine, Wis., just issued, shows that while gross sales fell somewhat below those of 1914 the earnings are very much higher. The gross sales of 1915 were, with one exception, the largest of any year since the company was established in 1842, and amounted to $14,058,631. Earnings for 1915 were $1,931,824, compared with $966,697 in 1914. After paying $850,000 in preferred dividends and making an appropriation of an additional $500,000 for contingent losses, the earnings were equal to 7 per cent on the $8,300,000 outstanding common stock. The preferred stock outstanding is $12,150,000. The company during 1915 liquidated $1,000,000 more of the $12,000,000 bond issue of Feb. 1, 1914, and thus far has redeemed $2,500,000, leaving $9,500,000 outstanding. This is to be taken care of by three annual payments of $500,000 in 1916, 1917 and 1918, followed by eight annual payments of $1,000,000. The record of gross sales for the last four years is as follows: 1912, $14,026,633; 1913, $13,417,405; 1914, $14,395,384; 1915, $14,058,631.

New Prest-O-Lite Battery Plant Nearly Completed

INDIANAPOLIS, IND., March 17—The large addition to the main factory of the Prest-O-Lite Co., this city, to increase the production of its storage batteries is practically completed. The building is 400 x 100 ft., one story, and adds 40,000 sq. ft. The construction is reinforced concrete.

The present output of 400 batteries a day will be increased to 1200 as soon as the addition is completed.

White Declares Initial Dividend of 1¾ per Cent

CLEVELAND, OHIO, March 18—The White Motor Co. has declared an initial dividend of 1¾ per cent, payable April 8 to holders of record March 25.

In connection with the initial dividend of 1¾ per cent on the $16,000,000 stock, it is stated that the stock has been placed on a regular 7 per cent per annum basis.

Dividends Declared

Kelly-Springfield Tire Co.; quarterly of 1½ per cent on 6 per cent preferred.

Automobile Securities Active

Chevrolet Reaches New High Mark of 160—General Motors Rises 15 Points

NEW YORK CITY, March 21—The automobile securities last week were featured by sharp gains ranging from 1 to 15 points. Following quite a protracted period of reaction, another boom is on in Wall Street. Not in months has there been such a display of activity and strength as was witnessed on the Stock Exchange this week. Those who held onto their automobile shares during the reaction will find gratifying gains for this week. Especially in Chevrolet and General Motors issues, will those who held for a turn for higher quotations be rewarded for their patience. Last week both Chevrolet and General Motors saw a sharp rise of 13 and 15 points, respectively. Chevrolet reached a new high mark of 167 on Wednesday, an advance of 30 points within two weeks. At times the demand for the stock was such that offerings had to be made by controlling financial interests to prevent a runaway market.

The week's development included a revival of the proposition by certain interests in General Motors management for the creation of a stock voting trust. The new circular, which had thirteen signers owning 8047 shares, or 2½ per cent of the total outstanding stock, urged the voting trust for the protection of the stockholders. The attempt to create a voting trust in that company's stock does not seem likely to succeed. W. C. Durant and his associates, against whom the voting trust is aimed, own 162,437 shares of General Motors stock out of a total of 316,000, or 51 per cent. Of this holding 104,000 shares are of common stock, and the balance preferred. The Durant interests, it is stated, have refused offers of additional shares and have officially announced that no more stock would be accepted under the terms of the original offer of exchange.

Studebaker, Maxwell and Overland issues were strong at the closing on Saturday. Maxwell common went up 12½ points to 72½ points; its second preferred rose 2 points to 85; and the first preferred rose 1 point to 46½. Studebaker common closed at 146, a gain of 6 points. Willys-Overland common, after a gain of 12 points during the previous week, again rose, reaching 234, just 6 points higher. Paige-Detroit stock was strong at 690, just 15 points higher than last week.

Tire issues within the past two weeks have shown strength with substantial gains. Last week Ajax rose 3 points; Goodrich common went up 2 points as did that of Goodyear; Kelly-Springfield's new common rose 5¼ points to 74¼, and U. S. Rubber common closed at 53½, a gain of 2 points.

Chalmers Show Rise

Saturday, which is generally an off day on the Detroit Stock Exchange, was a very lively day. The cause was the demand for Reo Motor Truck Co.'s shares and for Chalmers shares. The former, which was quoted at 25¾ and 27 on Friday, was at 28½ bid and 29½ asked at the close of the exchange to-day. Rumors that the company may declare an extra dividend soon and that its business was exceptionally good, have been going around the brokers' offices all week. The big business of the Chalmers company is also said to be the reason for this stock making a gain of 6 points. Demand continues to be steady for Continental Motor stock. From Muskegon comes the report that Detroit brokers are asking owners of the stock there for 30-day options at $40 a share, which is $5 higher than the stock quotes now, and also offer $1 a share to bind the option. Although much of the stock is held by Muskegon people very little is being offered for sale.

The Week in the Industry

Motor Men in New Roles

Murray Duplex Power Secretary—Fred Murray has been appointed secretary of the Duplex Power Car Co., Charlotte, Mich., succeeding the late M. J. Lampson.

Biggam Detroit Trailer Sales Mgr.—H. F. Biggam has been appointed sales manager of the Detroit Trailer Co. He was formerly with the Troy Wagon Works, Troy, Ohio.

Scothorn Joins Steel Products—R. J. Scothorn, formerly manager of the Detroit office of the Columbus Bolt Works, has joined the sales department of the Detroit Steel Products Co., Cleveland, Ohio.

Baily Body Adds—The Baily Mfg. Co. North Wales, Pa., which manufactures automobile bodies, is extending its plant to more than double its present capacity.

Baumbach Appointed Manager—W. L. Baumbach, secretary and treasurer of the Badger Tire Repair Co., 454 Jackson Street, Milwaukee, State agent for the Kelly-Springfield tires, has taken active charge of the business as general manager.

Los Angeles Cole Changes Hands—The Cole Motor Car Co., Los Angeles, Cal., which has been operated as a factory branch under the management of Ed. F. Harris, has been taken over by J. L. Irving, who has been distributer of the Enger in southern California and Arizona for the past year. The Irving Motor Car Co. is now distributer of both lines, and Ed. F. Harris has been appointed sales manager by the head of the concern, Mr. Irving.

Morehouse Joins H. A. L.—J. C. Morehouse who during the past two years was a traveling representative of the Maxwell Motor Co. has been appointed sales manager of the H. A. Lozier Co., Cleveland, Ohio, which makes the H. A. L. twelve.

Bayless Joins Champion Plug Co.—B. H. Bayless, formerly in charge of the advertising department of Berdan & Co., Toledo, Ohio, has joined the advertising department of the Champion Spark Plug Co., Toledo, Ohio, where he will assist H. L. Corey, advertising manager.

Wheeler Bowser Advertising Manager—C. D. Wheeler of Philadelphia is to be advertising manager of S. F. Bowser & Co., tank and pump manufacturers, Fort Wayne, Ind., to succeed G. A. Townsend, who resigned a short time ago. Mr. Wheeler for a number of years was advertising manager of the Fort Wayne Electric works; later he accepted a responsible position with the Santo Vacuum Cleaner Co., Philadelphia, where he has since resided.

Niblette Forms Tire Co.—The Niblette Rubber Co. has been organized, with H. B. Niblette at its head, to handle the products of the Rubber Products Co., Barberton, Ohio, manufacturer of Stronghold tires. The Niblette Company will be located at 1777 Broadway and will open for business immediately. Mr. Niblette severed his connection with the Goodrich Rubber Co. Jan. 1. For 5½ years he served as manager of the Goodrich branch at Buffalo, and for 11½ years previous to his Buffalo connection, he was connected with the New York branch of the same company.

Maus Joins Fisk Staff—J. B. Maus, for the last two years Eastern district manager of the Batavia Rubber Co., has joined the Fisk Rubber Co. of New York, where he will have charge of the export department at the general offices in Chicopee Falls, Mass.

Mr. Maus has been in the tire business for ten years.

The Automobile Calendar

March 18-25	Pittsburgh, Pa., Twelfth Annual Show, Automobile Dealers' Assn., Motor Square Garden.
March 25	San Diego, Cal., 50-Mile Automobile Track Race at Fair Grounds.
March 21-25	Deadwood, S. D., Show, Auditorium, Deadwood Business Club.
March 22-25	Lexington, Ky., Show, Woodland Auditorium.
March 25-April 1	Wheeling, W. Va., Show, Market Auditorium.
March 27-April 1	Danville, Ill., Show, Eastern Illinois Dealers.
March 27-April 1	Johnstown, Pa., Show, Auditorium; Johnstown Auto Show Promoters. A. E. Oldham, manager.
March 27-April 1	Zanesville, Ohio, First Annual Southeastern Show, Airdome.
March 28-April 3	Manchester, N. H., Show, Under Auspices Couture Bros. Academy.
April 1-8	Butte, Mont., Home Industry Electric & Auto Show, Holland Arena, H. W. West, Mgr.
April 3-8	Twin Falls, Idaho, Show, Oliver Tabernacle, B. H. Fuller, Mgr.
April 8	Corona, Cal., Race, Citrus Belt Racing Assn.
April 10-15	Seattle, Wash., Show, Arena.
April 12-15	Champaign, Ill., Show, Gymnasium Bldg., University, Ill.
April 14-16	Milwaukee, Wis., Garage-Circuit Exposition, Milwaukee Automobile Dealers.
April 15	Altoona, Pa., Pennsylvania State Motor Federation.
April 26-May 6	Oakland, Cal., First Annual Pacific Coast Motor Power & Automobile Show, Automobile Industries Assn.
May 6	Sioux City, Ia., Speedway Race, Sioux City Speedway Assn.
May 9-12	Hot Springs, Va., N. A. A. A. J. Meeting, The Homestead.
May 13	New York City, Sheepshead Bay Speedway Race. Metropolitan Trophy, 150 miles; Queens Cup, 50 miles; Coney Island Cup, 20 miles, and Brooklyn handicap for non-winners, 10 miles.
May 20	Chicago Non-Professional Speedway Race, Western Interclub Speedway Park.
May 26-27	Del Monte, Cal., Meeting, Three Divisions of National Assn. of Automobile Accessory Jobbers.
May 30	Tacoma, Wash., 100-Mile Speedway Race, Tacoma Speedway Assn.
May 30	Indianapolis Speedway Race.
May 31	Minneapolis, Minn., Speedway Race.

GRAY & DAVIS

Establish a Laboratory

In Detroit

IN order to afford maximum co-operation to manufacturers in Detroit and vicinity, Gray & Davis have established an engineering laboratory at 1602 Woodward Avenue, Detroit. In the past, engineering problems connected with electric starting-lighting were handled at the Boston plant, but under the new plan automobile designers will have the services of the Detroit laboratory at their disposal.

The laboratory will be under the management of C. M. Tichenor, long associated with Gray & Davis as engineer and factory superintendent. He will be assisted by a capable staff. A complete line of Gray & Davis systems are part of the laboratory equipment, and these units will be available for instant attachment on various engines, thus expediting experimental work in connection with new installations.

The Automobile

The Problems of Kerosene

Turning Kerosene into a Readily Combustible Gas, Less Easy Than to Vaporize Light Petroleum—Engines Easier to Make Than Carbureters

By A. Ludlow Clayden

TAKE an ordinary atomizing spray such as is used for medicinal spraying or for perfume, fill it with good light gasoline and then, whether the bulb be operated gently or vigorously, a fine blue flame will be obtained on placing a match to the nozzle.

Repeat the experiment with kerosene and the same clear flame will result, if the spray is worked vigorously, but, if it is operated gently the character of the flame will change; it will grow colored and finally, smoky.

Carry the spray close to a furnace wall and it will be seen that the clear flame is still obtainable from the kerosene with a fairly gently spraying, but the impure combustion is still produced by a very slow action of the bulb.

A well-known British engineer who had given much study to the kerosene carbureter problem was once asked what was the fundamental difficulty; why was it that an engine would run well at a good rate of speed on so many kerosene carbureters, but commence to misfire and choke directly the throttle was closed? He answered by asking another question. "Suppose," he said, "you had a furnace designed to take small knobs of coal at the rate of twenty a second and suddenly you changed the supply to lumps as big as your head at twenty a minute, what sort of a fire would you expect to get?"

That, in a sentence, is the explanation of the fundamental difficulty of kerosene carburetion.

The Process of Carburetion

In an automobile engine we take a liquid, spray it into fine particles, mix it with air, compress it and set fire to it, all within a small fraction of a second. In this small element of time four distinct things have to happen: First, the spraying of the fuel; second, its admixture with air; third, its compression; and fourth, its ignition. One might add a fifth requirement which is that the final charge shall burn completely in the small space of time taken by the piston to make its descent on the power stroke.

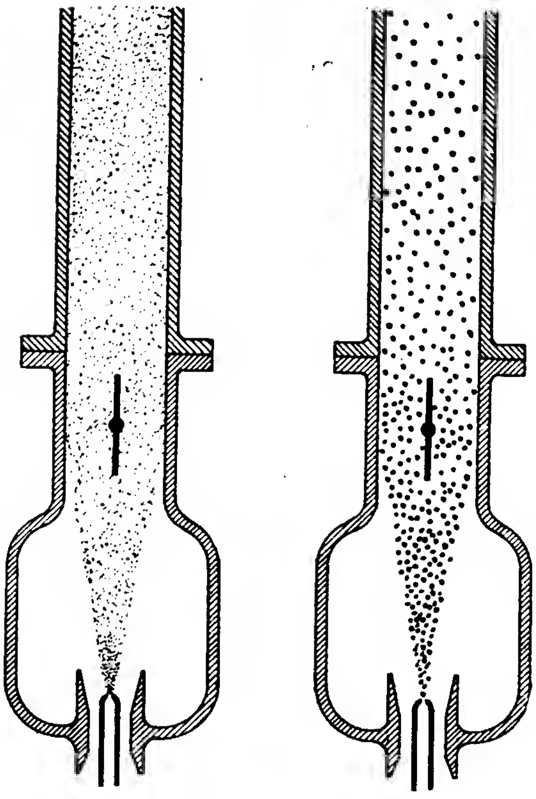
Gasoline, the old sort that we used to get some years ago, is a liquid that is easy to divide into fine particles by spraying; the spray once formed mixes readily with air, and the resulting mixture burns rapidly when compressed and ignited. Kerosene, being denser, is more difficult to separate into fine particles, is less easy to spread evenly throughout a bulk of air after spraying and does not burn so easily after ignition.

In other words, kerosene is more difficult to convert into an explosible gas and burns less readily when so converted. It is a matter of degree, there is no sharp line between gasoline and kerosene, but carbureting systems that work perfectly with a really light spirit, operate less successfully with a heavier grade, and the point where they will cease to operate with even moderate satisfaction is reached eventually as we increase the specific gravity of the petroleum.

The Human Analogy

To stretch a point it is possible to make a human analogy between gasoline and kerosene carburetion. The primitive South American Indian lived a life where nature supplied his every need. The climate caused his food to fall from the trees and spring from the ground without the need for tillage. The civilized man, developing sterner countries, struggled with nature and won by his skill in raising crops from less productive soils.

So with this problem of carburetion, gasoline converts to gas without coercion, kerosene resists until compelled by forces greater than its inherent powers of resistance.



Diagrammatic representation of difference between gasoline and kerosene spray at full throttle opening

The Effect of Temperature

Imagine a rain cloud letting fall small drops of water gently. If the air beneath is below freezing the drops will reach the earth as globules of ice. Assume the air warmer, a trifle above freezing up to say 60 deg., and the rain will fall as such, reaching the ground in drops and wetting the earth on which it falls. Raise the temperature still further, to 100 deg. say, and the rain, if fine enough, will dissolve in the air as it falls; it will merely create humidity and will not reach the ground till the air is saturated or chilled by the fall.

Air is to gasoline hot; to kerosene it is in the intermediate stage, to crude oil it is little better than freezing.

There is another thing to be remembered in this connection. Following the same analogy, imagine the air above 212 deg. Then the falling rain would turn to steam and we should have an atmosphere composed of mixed air and water in gaseous form, *not* wet air. In vaporizing gasoline or kerosene the aim is to have air wet with the fuel, but not dripping wet. To have air that has picked up oil and holds it in suspension, air that is neither hot enough to boil it nor cold enough to let it recondense into drops. With the first product of petroleum distillation commonly called gasoline, air at normal atmospheric temperatures is at just about the correct degree of heat. For kerosene it is considerably too cold.

Density a Problem of Its Own

So far it might seem that the solution of the kerosene carbureter problem consisted merely in the provision of enough hot air, but this is not entirely all. If the expansion and compression of air had no effect upon its ability to hold liquids in gaseous suspension, then heat would supply every need; but air entering an automobile engine is first expanded and then compressed and this upsets the condition of any liquid suspended within it.

Air enters the engine because it is sucked in, which means that the descending piston makes a "hole in the atmosphere" so to speak, and the outside air rushes through the inlet valve to fill the "hole." To do this it has to pass through the carbureter and by the valve and these things put resistance in the way, which means that the pressure inside the cylinder at the middle of the intake stroke is smaller than the pressure in the manifold, and the pressure in the manifold is smaller than that of the atmosphere outside. If this were not so there would be no inward flow whatever.

Now, air saturated with a liquid, as it is in passing the spray nozzle of a carbureter, throws down some of that liquid in the form of drops immediately it is rarefied, which means that air entering an engine and saturated at the nozzle, deposits some of the fuel in the manifold and still more inside the cylinder itself.

Liquids form drops when they condense because of the surface tension which is present in all liquids. The size of the normal drop formed depends upon the tension, which is variable, and the surface tension of kerosene is greater than that of gasoline. This means that when saturated air carrying kerosene vapor expands and so throws down some of the kerosene, the drops formed are larger than would be drops of gasoline deposited under similar circumstances.

Again, when deposition occurs inside the cylinder, the heat resulting upon compression tends to cause re-vaporization. Here the kerosene is at a further disadvantage for two reasons. Firstly it needs a higher temperature to vaporize a drop of kerosene and secondly, the drop being larger a given temperature takes longer to accomplish the vaporization.

With gasoline as a fuel there is no doubt but that substantial drops of liquid do actually enter the cylinder or are deposited there; they are either vaporized during the compression stroke and then burnt as gas, or they are *both* vaporized *and* burnt during the explosion stroke. This can sometimes happen with kerosene; it need not always happen with gasoline. When the exhaust of an engine is smoky and strong smelling, not due to lubricating oil, it means that the exhaust contains drops of fuel that are still only partly consumed and are being wastefully burnt in the open atmosphere.

Thus it is obvious that it is fundamentally less easy to obtain a good efficient gas from kerosene.

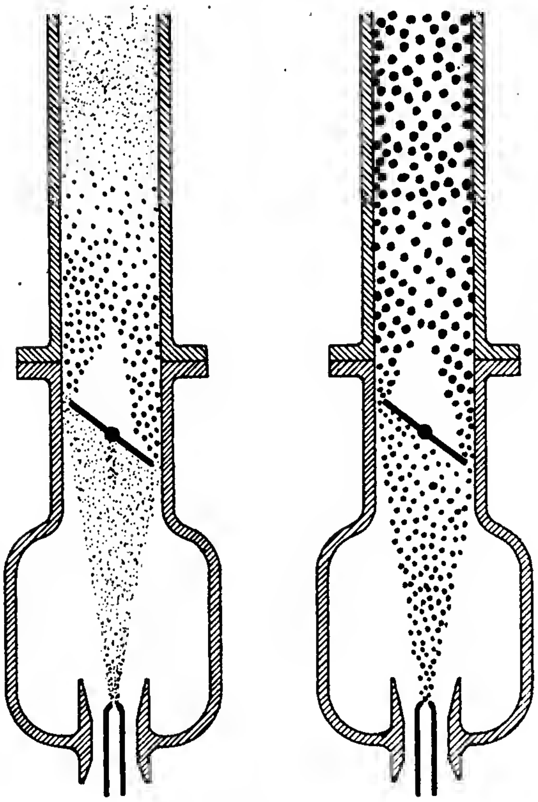
Disorganizing Effect of Throttling

This is not difficult of solution, if we consider only one condition of running. Assume a certain setting of the carbureter, a certain speed of inflow of air and consequently a certain degree of compression accruing in a definite time element, and it would be easy to find the right degree of heat to apply to the incoming air to secure proper vaporization of the kerosene; always providing that it was divided finely enough in the spray nozzle to enable the air to absorb it in the limited time.

But this is not the condition of running of an automobile engine for more than a few moments at a time. Suppose everything is arranged for running at 1000 r.p.m. with full open throttle, as for example climbing a moderate hill. When the top is reached the throttle may be closed, leaving the speed the same. If this happens the closing of the throttle restricts the passage of the air, the pressure within the manifold and the cylinder is lowered and the air inside has no longer the same retaining power for vapor. Of course the air is picking up less kerosene from the nozzle because less air is passing it, but we must remember that the rarefied air is all the time trying to throw down the liquid; the liquid is trying to form into drops. To hold any liquid whatever at the lowered pressure the air must be hotter than it required to be with the throttle fully open and, the compression being lowered, there is less heat instead of more available for re-vaporizing such fuel as does condense. Furthermore, the fuel is sprayed no more finely on account of the lessened velocity past the nozzle, rather the contrary is true.

Suppose the throttle is left open and the speed increases as the level road is reached. This also upsets the equilibrium for increasing the speed of flow is accompanied by a drop in pressure in the manifold and the cylinder, while also affecting the character of the spray. These same changes in condition occur whether the fuel is gasoline or kerosene, but the ease of dividing the lighter liquid into a very fine spray together with the wide range of temperature during which it will remain suspended in the air make it possible to run an engine on gasoline at all the speeds and throttle positions required in automobile service without special provision for supplying heat. Kerosene being a less amenable fluid cannot be so used unless the proper amount of heat is supplied at the proper point and kept under proper control.

This sounds simple, but how far from simple it really is the thousands who have tried to overcome the problem can tell. There are all sorts of ways which will *approach* a solution, which will give a passable result, but no device has yet been shown to be capable of giving *exactly* the same results as a good gasoline carbureter fed with good gasoline, and applied to an ordinary type of gasoline engine in the conventional way.



Diagrammatic representation of difference between gasoline and kerosene spray at low throttle opening

The foregoing has given only some of the reasons for the difficulty of proper kerosene carburetion. Another cause, which is frequently overlooked is the fact that the limits of proportion for a combustible mixture of kerosene and air are much narrower than those for air and gasoline. Various experimenters who have studied the question scientifically have decided that ignitible gas is formed by gasoline vapor mixed with air in the proportion of anything between 1 per cent and 5.3 per cent; whereas vaporized kerosene has only about half this latitude. This means that if we design a carbureter to give a normal mixture of 3 per cent gasoline vapor to air, it can run weak down to 1 or rich up to 5 per cent and still fire regularly in the engine. A kerosene carbureter designed for the same normal could not operate weaker than 2 per cent nor richer than 4 per cent. This, of course, means that the valves or compensating jets making up a kerosene carbureter must be just twice as accurate in functioning as they need to be in a gasoline instrument.

Limitations of Heating

It has been stated that the solution of the problem is not merely the supply of very hot air, and the reason for this has been explained partially. It is now time to point out a chemical reason why the degree of heat that can be employed is limited.

Kerosene is a mixture of oils of all sorts of density and all sorts of characteristics from the vaporization viewpoint. Each of these oils has its own igniting temperature and the range covered is a wide one. Thus, if kerosene is fed into air that is hot enough to vaporize the heaviest fractions in it, the lighter fractions can easily be ignited and partially burnt before the charge enters the engine.

In the process of making gasoline from kerosene by cracking, the oil is subjected to considerable heat and also to pressure, the products being gasoline plus some heavy oil plus some tarry matter. If, therefore, a kerosene vaporizer is designed so that it gets hot enough to start cracking it is inevitable that trouble will arise from tarry deposits, either in the vaporizer or in the engine itself.

Two Lines of Possibility

So far the term kerosene carbureter has been used in a loose sense and it is now time to define more accurately the difference between a carbureter and a vaporizer. In a carbureter the liquid and air are simply mixed by mechanical spraying and there is no temperature regulation. In a vaporizer heat is utilized to convert the fuel into vapor in the presence of a small quantity of air which thus becomes saturated or nearly so, and this saturated "gas" is then mixed with more air before passing into the engine. In the case of the carbureter we mix air and fuel direct, in the vaporizer we mix air and vapor and require an additional piece of apparatus to convert the liquid into vapor.

Those who have attacked the problem scientifically are frequently of the opinion that the most satisfactory basis for working out a kerosene carbureter is to pass something less than 20 per cent of the air through the vaporizer and to mix this with the remaining 80 per cent immediately before the charge passes into the engine cylinder. The effect of this is, theoretically, much the same as the direct admixture of a volatile spirit and air. Suppose the kerosene vapor to be hot and perfectly dry, as soon as it meets the cooler main air supply the liquid immediately turns to a fog or an infinite number of minute particles, forming much the same mixture as is obtained through the direct spraying of gasoline into the whole air charge in a good carbureter. It is at this very point that the greatest difficulty occurs. The fog of kerosene is very unstable and sudden changes in temperature or pressure can make it throw down big drops of liquid very rapidly. Remembering the furnace analogy, if the fog of correct mixture resembles the many small pieces of coal evenly spread over the grate it needs very little to instantly change the charge to the few scattered lumps "as big as your head" whereupon combustion either ceases altogether or becomes very imperfect.

This means that there are two distinct difficulties in using kerosene. Firstly, in order to form a proper fog we have to do something besides spraying the fuel; we have to apply just the right amount of heat and to control the proportions of air used in forming the vapor and air used in diluting the vapor with great accuracy. Secondly, having thus obtained the fog, or readily combustible mixture of kerosene and air, we have then to so control its pressure and temperature that it does not lose its character until the actual instant of ignition.

Trouble Caused by Throttling

In a gasoline carbureter the amount of fuel picked up is controlled by the amount of air passing through, and by closing the throttle we restrict the amount of air. This restriction, as already mentioned, causes a considerable drop in pressure in the manifold. Even with gasoline this pressure drop causes some to condense, but this can be prevented by warmth as supplied by a water-jacketed manifold.

With kerosene the drop in pressure caused by the throttle produces a much heavier condensation and the simple application of heat cannot cause re-evaporation. Once let the "fog" turn to large drops and those drops must go through the vaporization process of mixing with a little air and proper heat before they can be returned to the fog condition. Worse than this, heat cannot prevent the condensation from taking place if the drop in pressure is severe unless the temperature is so high that it will start cracking the kerosene. Thus to get perfect combustion it appears that we cannot superimpose a throttle upon a kerosene vaporizer in the same simple manner that is possible with gasoline carbureters.

Many Possibilities

All the foregoing may give the impression that this problem of kerosene burning is terribly difficult and might suggest that there is little hope for a vaporizer that is nearly as simple as a gasoline carbureter. In a sense this is the truth, and in another sense it is not so. There are many different devices which have been tried from time to time, and many that are now being experimented with, which give fairly good results. If we are prepared to sacrifice some of the flexibility of the engine, as can be done on trucks and to a still greater extent on tractors, it is easy to buy a vaporizer that will do its work well and economically. It is a matter of the difference between that which is perfection and that which is sufficiently satisfactory for use. With good gasoline and a good carbureter we can obtain a perfect gas for a wide range of speed and load. With kerosene we cannot obtain as good a gas over as wide a range., and the purpose of this analysis of the problems is to show in general terms why kerosene is so much more difficult to handle.

There is no fundamental, insurmountable difficulty preventing the general use of kerosene in automobile engines. It is possible to design a vaporizer to give perfect results, but such an instrument would be quite elaborate and would probably need the manipulation of more than one control lever or pedal when altering the speed of the engine while running.

The gasoline carbureter began in a very simple form because of the highly volatile spirit that was then obtainable. The kerosene vaporizer is beginning in complicated shape, but the whole history of engineering goes to show that a proper study of both the chemical and mechanical problems involved will enable simplifications till the ideal is attained.

Special Types of Engine

Hitherto it is the problem of making a vaporizer for the ordinary kind of automobile engine that has been considered, but there is another way of attacking the question and this is by devising a complete engine for the use of kerosene or some oil heavier than gasoline.

Fundamentally the gasoline automobile engine is a gas engine, its power being obtained from the explosive force of a mixture of *gas* and air. There are other oil engines which use the liquid fuel as a liquid, without previous vaporization. There is also an intermediate type burning part gas and part liquid.

These engines are all heavy, are clumsy as compared with automobile engines and have a narrow range of speed with a low maximum. Yet this was also true of the gas engine from which the automobile motor has been developed. There is no reason why the true oil engine should not be capable of development into a high speed, light type also. It has taken twenty years and more of concentrated effort to produce the automobile engine, most of the development taking place in the last ten years. In the light of the knowledge obtained regarding the materials, the lubrication and the mechanical things generally which we now possess, it should not take long to develop a high speed *oil* engine if a number of our automobile engineers gave the problem their sincere attention.

In the Diesel engine, which is the most economical engine ever made, the power is derived from the heat of the combustion of a liquid and not from the force of explosion of a gas. Into the cylinder pure air is drawn; this air is compressed to a high degree and, when fully compressed, oil is injected in a fine spray. The temperature of the high compression is such that the oil takes fire and burns, evolving heat and driving the piston down. The injection of the oil continues for a large part of the power stroke being maintained long after combustion has commenced.. Power is controllable by variation in the duration of the injection; whatever oil is injected is burned up completely and either a small amount or a large amount can be employed by varying the cut off of the injector valve. The hot bulb engine, sometimes called the semi-Diesel (a peculiarly inapt term) draws in pure air and compresses it to a much lower degree than is done in the Diesel cylinder. Part of the cylinder head, usually an attachment of globular form, is kept at a temperature something below red heat and against this surface a jet of oil is injected by a small pump as the piston passes over the top dead point. This oil catches fire and burns, but it is also partly cracked by contact with the hot bulb and the lighter fractions may explode as a gas. Similarly the heavier fractions may fail to burn altogether. In the Diesel engine there is no time for cracking, the oil lighting as it emerges from the jet.

Has Internal Vaporizer

The hot bulb engine is really an engine with a vaporizer contained within the cylinder, and though this inclosure reduces the trouble of vaporization while the load is steady and the temperature and pressure in the cylinder also fairly constant, as soon as an attempt is made to vary the power very much by altering the amount of the oil supplied all the usual vaporizer troubles enter and imperfect combustion results.

The difficulty of applying either Diesel or hot bulb engines to any service requiring greatly varied power small in total amount is that the only control is on the quantity of fuel delivered into the cylinder during the power stroke. A big Diesel engine taking perhaps a wineglass full of oil per stroke can be controlled easily, for there is no mechanical difficulty in dividing that amount of oil into two equal parts or even cutting it down to a tenth or less of the total. When, however, we want a drop or two per stroke it is a very different mechanical problem to provide ready means for cutting down to a tenth of a *drop* or less. However, there is no impossibility. Given sufficient money and permitting a large amount of delicate apparatus a small, high speed Diesel engine with a delicate control could be built without very much trouble. It would be too complicated and probably too heavy for automobile use, but that does not mean it is essentially so. Development ought to enable simultaneous reduction of both weight and complication.

Needs Combined Effort

Whatever may be done to develop kerosene carbureters for existing types of automobile engine, and whatever may be done to develop new and better types of true oil engine, there is no doubt that it will necessitate the combined efforts of all automobile engineers. There is no great discovery to wait for that will show us a royal road to success. It is a matter that can be solved by work, and a matter that calls for the freest interchange of thought.

Every man to-day who holds what he thinks to be a valuable secret and tries to keep it to himself is a traitor to his industry. The automobile industry is a big thing to-day; if we can solve this heavy oil question it is going to be infinitely bigger to-morrow.

Increasing the Thermal Efficiency

Possibilities of Altering the Otto Cycle Engine to Obtain 15 or 20 Per Cent Better Fuel Economy

By C. E. Sargent*

IN order to properly comprehend the problem of increasing the thermal efficiency of internal combustion automobile engines $\left\{\frac{\text{heat converted into useful work}}{\text{total heat supplied in fuel}}\right\}$ we will refer to diagram Fig. 1, in which, of the 100 per cent of heat supplied, 20 per cent is converted into work and 80 per cent lost or rejected in friction, cooling water radiation and exhaust.

To convert more heat into work it will be necessary to decrease one or more of the losses indicated, all of which are characteristic of internal combustion engines.

Mechanical Efficiency

With good workmanship, force-feed oiling and light reciprocating parts the mechanical efficiency $\left\{\frac{\text{b. hp.}}{\text{i. hp.}}\right\}$ is about as high as can be expected, and we may look for no further appreciable gain from that source; as a matter of fact, but 5 per cent of the total heat supplied seems a small amount for engine friction.

Waterjacket Losses

The loss of heat to the water jacket depends on the *difference* in temperature between the burning gases and the cylinder walls, the *time* the cylinder walls are exposed to the heat of the flame and the surface *exposed.* If we could maintain the combustion chamber at the same temperature as the inclosed gases there would be no difference in temperature and no transmission of heat, consequently no loss to the walls and water jacket, but such a temperature would not only destroy all vestige of lubrication, but would melt the cylinder walls and pistons.

The time per working stroke in which the difference of temperature exists is cut down by high speed, wherein lies the advantage of high piston speed in an engine of this type. The thermal efficiency of big guns lies in the missile speed—nearly 3000 ft. per second—while the maximum piston speed obtained in an engine cylinder probably never exceeds 40, and seldom averages over 20 ft. in the same unit of time. One of the most economical internal combustion engines ever designed had a free piston, which, returning to the cylinder by gravity, converted more heat units into work than has any engine with a restricted piston.

While the ratio of the explosion chamber surface to the volume it contains is one efficiency factor, and the requirements of a minimum quotient the rational reason for valves in the head, the advantages of multi-cylinder engines with their high speed, light reciprocating parts and minimum angular velocity variation seem to offset any thermal losses due to increased surface per unit of volume, a characteristic indigenous to this type.

Exhaust Losses

While small gains in efficiency have been made by reducing the mechanical friction and decreasing the losses to the water-jacket, loss of heat to exhaust is little considered.

Several compound engines of the internal combustion type have had a mushroom existence, but when one considers the added surface of a larger cylinder and the time in which the pressure after ignition drops to less than the pressure of compression, we see the improbability of reducing the losses by this means.

The ordinary engine is more efficient at full load then at partial load, but unfortunately the automobile engine operates at partial load most of the time, therefore, if we would increase the b. hp. per unit of fuel or the miles per gallon, it should be so designed that its thermal efficiency is greatest with average or partial loads, or at least is no less than with full load. In order to thoroughly comprehend our problem let Fig. 2 represent an indicator diagram of an internal combustion engine developing its full power, in which *AB* represents the piston stroke and atmospheric line; *C* the highest compression; *CD* the firing line; *DE* the expansion line and *E* the exhaust opening.

A cylinder full of mixture (*AB*) is compressed to *C* and ignited, raising the pressure to *D*, and as the piston moves down the pressure drops to *E*, where the exhaust opens. It is necessary to open the exhaust valve from 40 deg. to 60 deg. before the end of the working stroke in order to get rid of the back pressure on piston during the exhaust stroke. The release of this pressure, 30 to 40 lb. absolute, with its accompanying "bark," visible flame and red-hot exhaust manifold, is ample evidence of thermal inefficiency, even without the proof deduced by a diagram analysis, or heat balance.

Increased Expansion

If, instead of releasing a less volume of hot gas than the volume of cold mixture at the beginning of compression by opening the exhaust at *E*, Fig. 2, we carry the expansion of the burning charge 50 per cent further; releasing the gases at a lower pressure, at a lower temperature and at a point nearer the end of the working stroke, more heat will be turned into work, because less will be rejected in exhaust, less power will be required to open the exhaust valves, and the function of the muffler will become extinct. Fig. 3 shows a full load diagram of an engine carrying the expansion 50 per cent longer than the compression stroke, in which *AB* represents the length of cylinder and atmospheric pressure. The piston, starting at *B*, the beginning of stroke drawn in a charge to *G*, when admission is closed, and the absolute pressure in cylinder drops to *F* when piston reaches *A* at the end of the stroke. *FC* represents the compression line which crosses the atmospheric line at *G*.

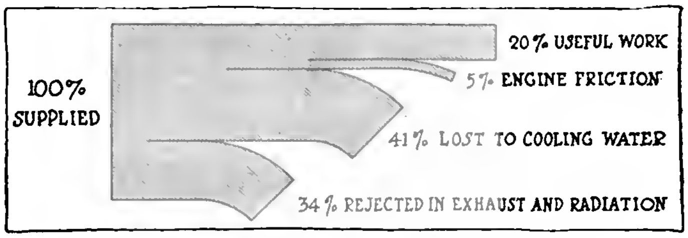


Fig. 1—Distribution of heat consumption

---

*Chief Engineer Lyons-Atlas Company.

With the same clearance as an engine having a stroke *BG*, the compression *BC*, the firing line *CD* and the expansion line from *D* to *E*, with the same mixture and timing, would not vary from those of the ordinary engine, but the shaded portion of the diagram *EAG* would represent the gain in power, using the same amount of fuel, by expanding 50 per cent more than the induction stroke.

The shaded portion of the diagram averages 16 per cent to 20 per cent of the whole, indicating a 20 per cent to 25 per cent increase in thermal efficiency, or a corresponding increase in power from the same amount of fuel. An engine using such a cycle may weigh a little more per horsepower output, just as a long-stroke motor is heavier than an engine with a square cylinder, and on account of the long stroke per pound of m.e.p. may have more mechanical friction, but, while the cooling surface per heat unit introduced is increased, the difference in temperature during the last third of the working stroke is so slight that an additional transfer of heat seems improbable.

The exhaust of an engine expanding its burning charge 50 per cent more than its compression stroke shows but a trace of flame, an evidence of complete combustion in the cylinders, where it belongs, and a reduction of the terminal temperature of about 1000 deg. Fahr. If the thermal efficiency is increased, the disposition of the rest of the heat is immaterial, though observation indicates that, while the loss in friction and water jacket is but slightly increased, the exhaust loses what the thermal efficiency gains. The average heat balance of five full load tests from a 50-hp. 10 by 20-in. engine, cutting off at about two-thirds its stroke, using the high value of fuel, is as follows:

Thermal efficiency on b. hp.	26.02
Engine friction	4.86
Radiation and exhaust	22.59
Water jacket	46.48

Of course, this high efficiency would be obtained only at full load or with an open throttle, a condition that seldom occurs in an automobile engine.

Partial Load Inefficiency

With an advanced ignition and a throttled mixture with its low compression an ordinary automobile engine, the terminal pressure will approach atmospheric, but the loss from wire drawing and the low compression is probably more serious than the exhaust gas losses at full load.

Fig. 4 shows the diagram of the ordinary automobile engine developing but partial load with the ignition advanced to compensate for the slow burning mixture, in which *AB* represents the atmospheric line and the piston travel; *BF* the rarefaction during the induction stroke; *FC* the compression; *CD* the firing, and *DA* the expansion line. The shaded portion shows the back pressure or loss in every cylinder during the partial load. As the area of the shaded part of the diagram, or the negative load, must be offset by a like amount of area above the atmospheric line, the fuel consumption of an idling engine is necessarily great, and because the average load on an automobile engine in which the intake is throttled necessarily has some back pressure, the thermal efficiency must be low.

The Negative Load

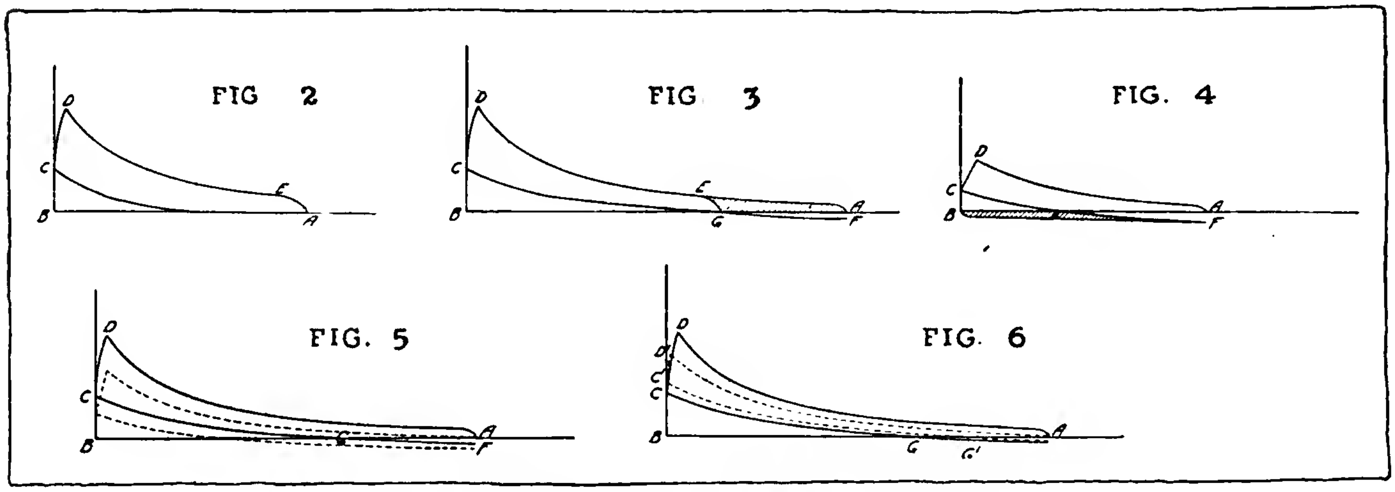
Tests have demonstrated that an engine driving a car on a smooth road at 20 m.p.h. will require no more fuel than when idling at the same speed. Every engine whose speed is regulated by the throttle opening develops a negative load which must be overcome by an equal positive pressure before it will deliver available power. This negative load decreases with a wide-open throttle, a condition, however, seldom obtained. The absolute pressure in the inlet manifold when car is operating at about one-half its maximum speed, or say 20 m.p.h., averages about 8 lb., therefore approximately 7 lb. more m.e.p. than the net load requires, is necessary under the average condition. When idling, an engine may be working against from 10 to 12 lb. back pressure, a sufficient cause for its high fuel consumption under no load. Tests of a 4½ by 5½-in. six-cylinder engine in 1912 by the Automobile Club of America showed the following thermal efficiencies:

Full throttle, r.p.m. 1113	17.8%
One-third throttle, r.p.m. 1039	15.1%
One-sixth throttle, r.p.m. 266	6.2%

The loss from low compression caused by a greater surafce for heat absorption per unit of volume is not shown on diagram, but manifests itself when a heat balance is obtained. As the load becomes lighter, the compression less, and the mixture weaker from having a larger per cent of carbon dioxide, the inflammation is necessarily slower, and the desirability of an earlier ignition is apparent if the maximum efficiency under adverse conditions is desired. While the car driver could, if he would, keep his ignition as early as possible consistent with smooth running, and in so doing maintain the highest possible efficiency, the ultimate solution of the timing problem for our present motors, in the author's opinion, is to automatically advance the time of ignition directly as the speed and inversely as the load—a combination which will insure the best economy during all ranges of load. With a late spark and slow burning mixture it is possible to generate more heat in the exhaust manifold than in the engine cylinders.

Cut-Off vs. Throttling

In order to prevent the wire drawing loss shown in Fig. 4, closing the admission valves earlier instead of throttling the



Indicator diagrams under varying load and running conditions mixture will reduce the m.e.p. without creating a back pressure, eliminating light load losses except those indigenous to low compression.

If the maximum cut-off is two-thirds the working stroke, Fig. 3, other conditions being the same, and we make this cut-off earlier as the load decreases, we will maintain a higher thermal efficiency during the whole range of load than is possible in the automobile engine controlled by a throttle in the suction pipe.

A carbureter properly designed for efficiency should provide a weaker mixture as the compression increases. A mixture too weak to ignite at atmospheric pressure will fire and do work if sufficiently compressed. A rich mixture is necessary in starting and with partial load, because the exhaust product content being constant and the compression less, the combustible molecules are not sufficiently close for proper chemical action, therefore there should be more of them in the same space to get rapid efficient firing. Blast furnace gas having as low as 90 B.t.u. per cubic feet, making 45 B.t.u. when mixed with a like amount of air, will not burn at atmospheric pressure, yet makes an ideal fuel when compressed to 180 lb. gage. Air containing less than 50 B.t.u. of gasoline vapor per cubic foot will not burn at atmospheric pressure, but when compressed sufficiently high will fire and do useful work.

If the molecules of a hydrocarbon are driven too close to the molecules of oxygen by compression, the generated heat will cause spontaneous combustion, but with a weak mixture high compression is necessary to bring them to a normal ignitable relation, therefore compression may be increased indirectly with the heat units supplied. In a Diesel engine in which the heat of compression is always sufficient for ignition, combustion takes place even with the smallest possible injection of fuel.

It is quite evident, therefore, for efficiency in automobile engines, that the fuel per unit should be less as compression increases to prevent spontaneous ignition and conversely should become richer as the pressure decreases for a high mean effective pressure.

The higher the compression, other things being equal, the greater the thermal efficiency, yet the compression must be below the critical point of premature ignition. If we weaken the mixture as the compression increases, the relation of the combustible molecules will remain constant, maintaining practically the same rapidity of inflammation. If a motor is designed to give a maximum compression and full rated load at two-thirds cut-off, as shown in full line diagram (Fig. 5), a better efficiency will be obtained at full load than is obtained in the ordinary automobile engine, because less heat goes out with the exhaust and more is turned into work. It already has been shown that if the point *G* is moved toward *B* as the load gets lighter, there will be no loss from wire drawing, but as the compression decreases the efficiency will become less, the molecules further apart and inflammation slower. Therefore the ignition must be advanced to obtain the dotted diagram in which the firing line is practically parallel to *CD*. Such a method of governing would materially increase the efficiency at half or partial load, which is the load most usually required of an automobile engine.

As an internal combustion engine which has no compression and fires at atmospheric pressure requires about five times as much fuel per b. hp. hour as an engine compressing to five atmospheres running on the Otto cycle, the desirability of keeping up the compression can readily be seen.

Highest Compression with Light Load

If, instead of moving the point of cut-off *G* toward *B*, leaving the mixture practically constant but taking in less gas, as less load is required, we move the cut-off point *G* toward *A*, or to *G'* (Fig. 6), and at the same time decrease the fuel per unit of air, the compression will be increased, rapidity of inflammation will remain practically constant, premature ignition will be improbable, the thermal efficiency should be practically as high as at full load and the initial pressure should be less, insuring smooth running at light loads. If the fuel is diminished as the compression increases in such a manner that there will be just enough fuel at maximum compression to drive the engine idle, and at the earliest cut-off to give the maximum m.e.p., the adjustment is complete. Should the fuel diminish faster than the compression increases at the latest cut-off, there would be a negative m.e.p. of compression and the engine would stop. Between extremes, full and no load, the fuel compensation is automatic, incurring complete and smokeless combustion. Such a cycle provides for a maximum or at least an average efficiency through the whole range of load. It eliminates the inefficiency of wire drawing and low compression. It provides a fixed fuel adjustment for full load with speed compensation only required. As the load gets lighter the fuel valve is throttled and the closing time of the induction valve retarded, a most simple mechanical problem.

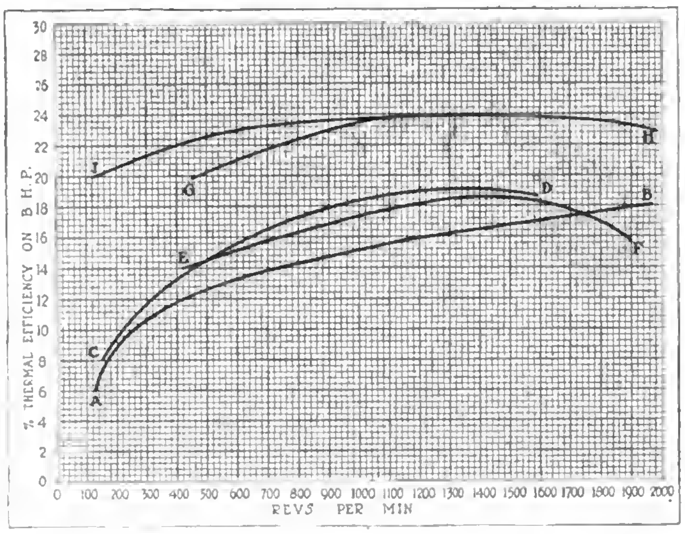


Fig. 7—Thermal efficiency curves from A. C. A. tests plotted against revolutions per minute

In such a cycle the molecular arrangement is such that the speed of inflammation is practically constant for all loads, therefore the time of ignition need be advanced only with the engine speed to get a uniform angle to the firing line.

Volumetric Efficiency

With such a cycle volumetric efficiency

$$\left\{\frac{\text{Volume of induction stroke}}{\text{Volume of gas induced}}\right\}$$

which governs the theoretical compression can be maintained at unity, as the flexible denominator of the equation can be readily varied.

If the compression at two-thirds cut-off and maximum load is 90 lb. absolute, the maximum compression at no load would be practically 144 lb., yet so attenuated would be the mixture that premature ignition would be impossible.

In Fig. 7 thermal efficiency curves *AB*, *CD* and *EF* were obtained from the tests by the Automobile Club of America of automobile engines, and probably show the average thermal efficiency of the majority of engines of this type.

While the available efficiencies of complete expansion engines are for full load and from larger cylinders, the total horsepower is practically the same as the horsepower of the engines from the tests of which the three curves were plotted.

The probable efficiency curve which would be obtained from an automobile engine expanding the working medium

Fig. 2—This interior of the Waltham speedometer shows guard G which protects the aluminum cup

Waltham Speedometer

World's Largest Watch Maker Develops Air-Friction Instrument—Deliveries Started

THE Waltham Watch Co., which five years ago took up the manufacture of automobile clocks and has since been marketing a complete line of these for motor cars and trucks, has further invaded the automobile field by the development of a new-principle speedometer, which it is about to start making deliveries of to automobile manufacturers. The company has taken up the development of this speedometer in the same systematic manner it did its automobile time pieces and has already organized a large department in its factory, the largest watch factory in the world, where it assembles all parts of the speedometer. These parts are being manufactured in the different departments of the watch factory, and watch standards of accuracy are applied to them. The development of this speedometer was started in the experimental department of the Waltham company three years ago and it has been going through the evolutionary stages since. The engineering departments of several large car builders have been utilized in a consulting capacity during this development stage. The instrument is to-day not an untried experiment but a known quantity and several manufacturers have been using it on test cars for months.

Production has already begun and the first lot of 25,000 is going through. The Waltham speedometer has been developed and is being manufactured to meet the demands of quality car builders yet lends itself to application on cars of all prices. That the Waltham company has entered the speedometer field in earnest is attested by the fact that negotiations are already well advanced for a country-wide selling and service system. The speedometer is being sold and guaranteed by the Waltham Watch Co. The Waltham speedometer will be sold separately or in various combinations with its time pieces.

The Waltham speedometer is an air-friction type and introduces a principle new in speed measuring and one which has not been previously used in any form of instrument. This speed-measuring part of the speedometer consists of two essentials called cups, one inverted and telescoping the other, with an air gap separating them. The driving cup is driven by a flexible shaft from the road wheel or transmission system. The driven cup, known as the indicating one, is inverted outside the driving cup. It is the air friction generated in the annular air space between the cups which constitutes the speed measuring medium of the instrument.

The relationship of these two cups is best shown in the lower right, Fig. 3. Each cup is in reality a double cup. Thus the revolving cup, *K*, consists of two concentric brass cups, *K*1 and *K*2, having an annular space 0.108 cm. between the two vertical walls called ribs for convenience. The cups *K* and *K*1 are rigidly mounted on the vertical shaft *S* so that when one revolves both revolve.

The driven or indicating cup *C* consists of two aluminum cups *C*1 and *C*2 attached together so that to all intents and purposes they form a single cup. These cups are extremely light, being made of aluminum 8/1000 of a centimeter thick. This means that 313 of these cup thicknesses would be required to make 1 in.

The aluminum cup *C* when in position in the instrument has the inner rib *C*2 floating in the annular space between the ribs *K*1 and *K*2 of the brass cup. The outer rib *C*1 of the aluminum cup floats outside of the brass rib *K*1. There is an air space at all times of one-half millimeter between the ribs of the brass and aluminum cups. On the outer face of the aluminum cup are the calibration figures to indicate the speed in miles per hour.

Fig. 2 is a photographic reproduction of the interior of the speedometer with the dial removed and shows how the aluminum cup telescopes the brass cup. The revolving of the brass cup generates the air friction which would revolve the aluminum cup also were it not for a regulating hair spring shown in the upper left, Fig. 3. This hair spring is so adjusted as to permit the correct oscillation of the indicating cup according to the speed. This regulation between the hair spring and the tendency to rotate is so accurate that the instrument indicates immediately all speed changes, and indicates as low as one-half mile per hour.

The principle of air friction between revolving concentric cups has been proved to be directly in proportion to the speed of the revolving cup, in this case the driven brass cup. It is this fact that makes a uniform calibration possible without adding compensating devices to gain this end. The principle of indicating speed through air friction is covered

Fig. 1—Waltham speedometer as mounted flush in a cowl or dash, showing trip reset, press button and crown

by patents controlled by the Waltham company. Comprehensive laboratory tests have proved that air friction is not influenced by heat, cold, or altitude up to 10,000 ft. The revolving cups have not to be carried in an air-tight compartment, and no sealing is necessary.

Incorporated in the instrument, Fig. 2, are season and trip odometers, both characterized by having particularly large figures spaced closely together. The odometer figures are black excepting those indicating tenths, which are red on both the trip and season. The trip odometer registers up to 999.9 miles and the season odometer to 99,999.9 miles and repeats. A quick reset device for the trip odometer is featured and appears in Fig. 1. Close to the dial is a press button and adjacent to it a reset crown. By turning the crown, or ball, and without pressing the button you can reset the tenths and total trip; but by pressing the button also you can reset the entire trip mileage ten times as fast.

The separate indicating wheels in the trip and season odometer are placed close together which makes it possible to use large figures. This placing of these wheels so is made possible by the use of an internal sun-and-planet gear drive between adjacent wheels.

In every speedometer what is known as the head incorporating the odometer and speed measuring device, constitutes one part of the instrument and the second and equally important part is made up of the flexible shaft together with other fittings including swivel joint, angle joint, etc., Fig. 4. The Waltham company has given as much attention to this second part of the instrument. The flexible shaft is a patented design of the company, and is made up of a series of interlocking links *L* held in position by a series of steel collars *M* so that it is impossible for the links to come apart. The chain is asembled from one end to the other and it is impossible to take it apart in the middle or at any other point except from either end. No rivets are employed in it, and it is such that it can be assembled or taken apart by an inexperienced workman without the aid of any tools and in a very short time. The only tool necessary in dismantling the chain is a pair of pliers to remove the locking male member *N* in the driving connection at either end. This done the entire linkage can be taken apart. All of the links *L* are heat treated nickel steel stampings. The collars *M* are of the same material. Surrounding the chain thus formed is the usual flexible casing with a leather cover as optional.

The swivel joint at the driving end of the flexible shaft is a Waltham design. Gears and shafts are heat treated. Ball bearings are used. The swivel joint consists of two, a pair of spiral bevels *SB* and a pair of bevel gears *B*. A feature of this swivel is the quick means of dismantling, in that the housing cap *H* is

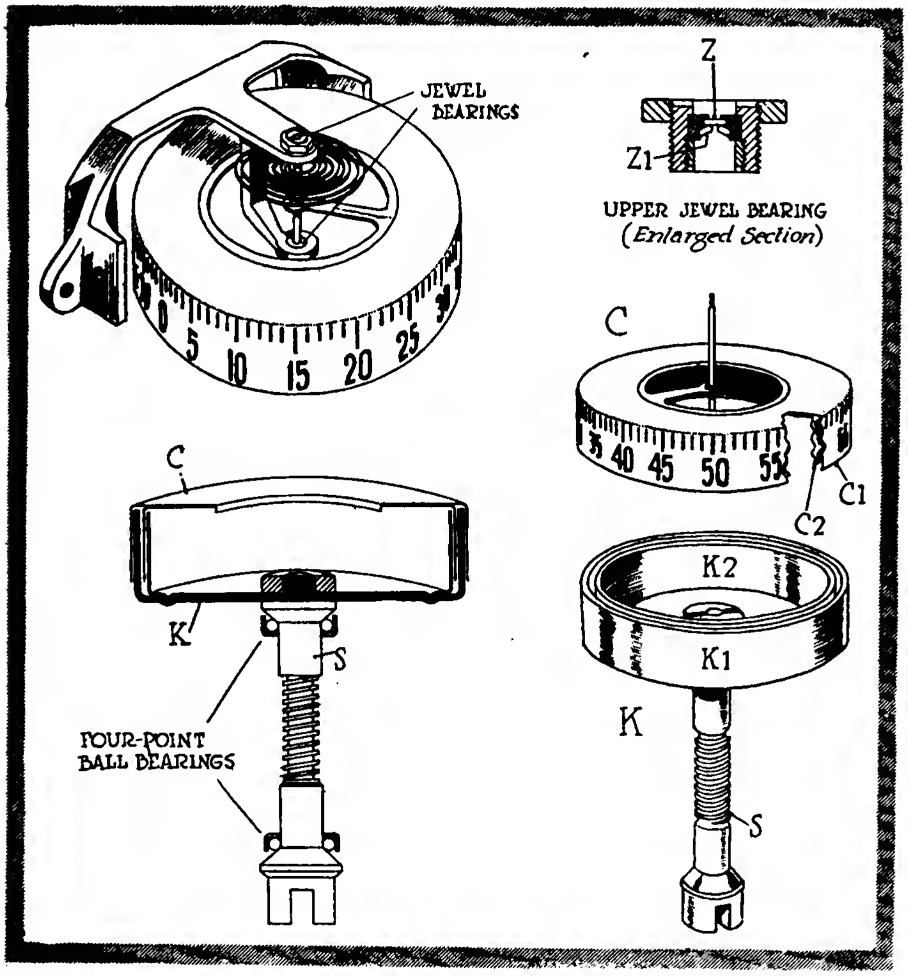

Fig. 3—Details of Waltham speedometer head:

Upper left—Aluminum indicating cup and supporting bracket, showing the use of sapphire-jeweled pivots supporting the cup. The sapphire-jewel bearing is shown in upper right and consists of two sapphires in each bearing. It is made up of an end jewel Z acting as a thrust bearing and a pivot jewel Z1. Both jewels are in settings. This complete double jewel bearing is used at the upper and lower ends of the shaft carrying the aluminum cup.

Lower right—The revolving brass cup K made up of two concentric cups K1 and K2 secured together, and above them the double aluminum cup C made up of the two parts C1 and C2.

Lower left—Section showing revolving brass cups carried on vertical shaft S, which revolves in two races of four-point ball bearings. The flexible shaft connects direct into the lower end of shaft S. The spiral on the center of this shaft is to drive the odometer mechanism.

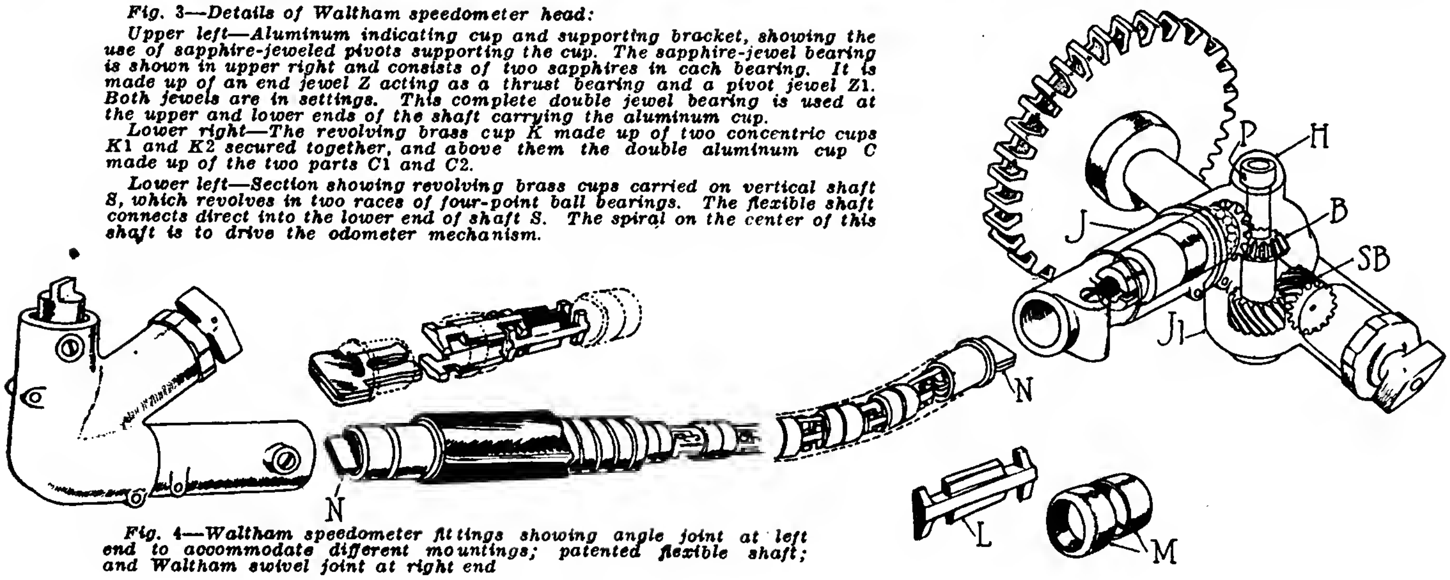

Fig. 4—Waltham speedometer fittings showing angle joint at left end to accommodate different mountings; patented flexible shaft; and Waltham swivel joint at right end

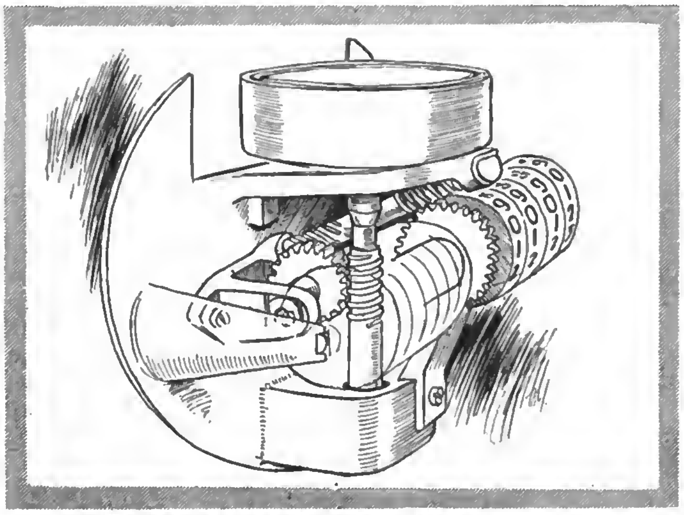

Fig. 5—Section showing oblique drive for odometer

snapped in position and when removed permits of removing the pin *P* from the retaining collar on the top of the shaft. This done the entire housing *J* is removed, leaving the vertical shaft carried on the lower part of the housing *J*1. A large capacity grease cup is an integral portion of the swivel joint.

In designing the driving mechanism the Waltham company has endeavored to have the swivel joint, shaft, and shaft casing, interchangeable with other standard instruments. The revolving brass cups *K*, Fig. 3, must revolve 1008 times to the mile. With the aid of gear ratios in the angle joint or swivel joint, Fig. 4, the flexible shaft may revolve at either 680 or 1008.

The assembly of the head of the Waltham speedometer is such that the complete group illustrated in Fig. 5 is placed within the case or shell as a unit. With this unit goes a guard for the indicating aluminum cup shown in another illustration. The dial showing car speed as well as trip and season odometer is commendably plain, making it correspondingly easy to see the large indicating figures.

Shorter Races Feature 1916 Schedule

Speedway-Owned Racing Cars and Selection of Master Driver and Car—Other High Lights

ALTHOUGH plans for 1916 racing are as yet far from complete, a survey of the events already carded and of those looming up as possibilities indicates that the coming season will far surpass previous years not only in the number of contests held, but also in importance and national interest. It is a foregone conclusion that higher speeds will be made in a number of races than ever before, for track surfaces will be more conducive to record-breaking speed, races will be shorter and cars will be faster.

The most interesting development of the 1916 season is that practically all of the speedway events, at least, will be shorter than previously, only one race of importance, the Montamarathon at Tacoma, being longer than last year. This tendency toward shorter races was manifested during the latter part of the 1915 contest season and the idea received such unmistakable approval from the public and racing fraternity alike that its general adoption seems inevitable. Short, snappy races with plenty of dash and higher speed than the drivers would dare to attempt in a long race should draw large crowds and go a long way toward permeating the general public with a wider interest in and enthusiasm for the automobile industry.

Indianapolis may be said to have inaugurated this movement for shorter races by its announcement last fall that the Hoosier Memorial Day classic, famous throughout racing history as the 500-mile race, would appear on the 1916 schedule as a 300-mile contest, the purse being correspondingly reduced from $50,000 to $30,000. Seat prices for spectators and entrance fees for racers are also lower, while the speed requirements are higher, 80 m.p.h. now being necessary to qualify instead of 75. Only thirty-three cars will be permitted to start this year in the brick-track speed battle.

Chicago has also gone in for shorter contests, a 300-mile event replacing the 500-mile race of 1915.

Sheepshead Bay is to open its season with four short races, the longest being the Metropolitan trophy event which calls for 90 m.p.h. to qualify, the 150-mile race to be called in ninety minutes. The other races are for 50, 20 and 10 miles, respectively.

Sioux City's 300-mile contest of 1915 is to be replaced this year by 50 and 100-mile events.

These examples will suffice to demonstrate that the speedway managements have realized that the public loses interest in races that are too long drawn out and in the monotony of a 500-mile grind fails to appreciate the bursts of speed and bits of skilful driving which flash forth now and then. What the public likes is a series of brisk, short, speedy events where all the finer points are more forcibly brought out instead of being lost in an endless succession of uneventful laps. The strong hold of horse-racing on the general public is a simple and conclusive proof of this psychological principle.

Speedway Racing Teams

Another important development which will first become apparent during the coming racing season is the début of speedway-owned racing teams. The formation of the Indianapolis Racing Team Co. and the Prest-O-Lite Racing Team Co. last September and the announcement that the first-named organization had bought two Peugeot racing cars and that Premier racers were to be built, while the second intended to use the four Maxwells, were followed by several similar purchases of racing cars by speedway interests. Harry S. Harkness, president of the Sheepshead Bay speedway, sent Carl Limberg to Paris this winter where he bought the three Delage racing cars which appeared in the 1914 French Grand Prix and brought them with all spare parts, etc., to New York, where he already had the Delage driven by Limberg in the Astor Cup race last fall. After being overhauled and fitted with new bodies, these cars will race as a team on the speedway circuit during the coming season under the management of Limberg, who will also drive one of them. It was also recently anounced that the Sioux City speedway was negotiating for the purchase of two of the Duesenberg racers. This deal, if successfully consummated, will bring the number of speedway-owned racing cars up to fourteen. There are also a number of special racing machines now being constructed which will probably figure in the 1916 races, Ray Harroun's 250-hp. free-for-all twelve being one of the projected speed demons. Harroun has also bought the Maxwell racing team's equipment and the three 450-in. cars so he may be a factor in the unrestricted events.

The Chevrolet brothers plan to race three Frontenac cars this season and hope to have one of them in shape in time for the Sheepshead Bay opening May 13 and two for Indianapolis on May 30. These cars will have aluminum motors, among other unusual features, are expected to develop 125 hp. and to weigh under 1750 lb. The three Crawford specials to be managed by Wm. Chandler will also bear watching. There are several well-known car manufacturing concerns rumored to be preparing racing cars for the coming season, although they are keeping things dark.

To Select Master Driver and Car

This year for the first time the contest board of the American Automobile Association will select the master driver and the master car in the 1916 speedway and road-racing circuit. While the system of determining the standing of the various contestants and their cars has not yet been definitely decided upon, it has been suggested that a gold medal carrying the profile of the winning driver and a cash prize as well be hung up.

Last summer and fall witnessed a regular avalanche of speedway plans all over the country and while most of these plans seem to have been abandoned, several speedways have been added to the list and others are still possibilities. The big centers of interest, however, continue to be Sheepshead Bay, Chicago, Twin City, Tacoma, Omaha, Des Moines, Indianapolis and Sioux City, all eight of which have important races scheduled for the 1916 season. Ascot, the new speedway developed in Los Angeles, has already held successful races this spring and Philadelphia begins to loom up as a a speedway town, its track being nearly completed.

Cincinnati's projected speedway also seems to be progressing, while there are several others which may also be classed as possible developments during the year. Last summer and fall speedway promotion movements were undertaken in Cleveland, St. Louis, Pittsburgh, New Orleans, Louisville, Kansas City, St. Joseph, Dallas, Birmingham and Detroit. Some of these proposed tracks have apparently faded into dreams which will probably never be realized and others promise only a small measure of attainment.

Of the established speedways, four have board surfaces, Sheepshead Bay, Chicago, Des Moines and Omaha, the board track proving lively and very fast with plenty of elasticity and also having the advantage that it is not so susceptible to heat on hot summer days as some of the other surfaces. Tacoma has a combination surface, the foundation being board with an asphalt covering. The Narragansett and Ascot speedways also have asphalt surfaces, that of the Twin City track is concrete, the Indianapolis speedway is brick and Sioux City races are run over a dirt surface.

Twenty-one Speedway Dates

There are twenty-one dates scheduled for speedway races of all sorts at the present time and the addition of a number of other events may be expected as the season advances and the plans of speedway managers round into more mature form. The longest races are for 500 miles, there being five of these on the card at present. A glance at the calendar in the right column will bring out emphatically the great number of short-distance events announced by the speedways this year. Of course, several of the important races like the Astor cup, to be held at Sheepshead Bay, Sept. 30, have not yet assumed final form and this race will be at least 300 miles.

Several invitation races will be held this year and the non-professional race to be held at Chicago on May 20 bids fair to be tremendously popular, many of the amateur drivers having already taken their cars out for practice on the course and some good time being recorded.

Corona enjoys the distinction of opening a new class of speed contest, its 300-mile Grand Prix on April 8 being designated as a boulevard race, as distinct from a speedway, road or track event.

The only road races on the card so far are the Elgin classics to be run off Aug. 18 and 19 and the Vanderbilt cup and Grand Prize which will be held sometime in November at Santa Monica, Cal. There was some talk of having a whole week's racing at Elgin when it was thought possible that the Vanderbilt and Grand Prix might be secured for the Watch City, but now it looks as though the regular two-day Elgin program will be sufficient, the regular Elgin classics, the Elgin national trophy race and the Chicago Automobile Club cup contest, being held during the two days.

Six cities already have track race dates arranged, the Galesburg race on June 20 being for 100 miles. Details of the other programs are not yet available, but most of them will probably be made up of several short events.

Only one hillclimb is scheduled for the coming season at present though it is hoped that more will be announced later. The one now on the card is the 13-mile event to be held Aug. 11 and 12 at Pike's Peak, which should present a sufficiently difficult grade for the most ardent devotees of the art of ascension. To still further stimulate the interest in the affair, the management offers a generous purse—$5,400—to successful contestants.

One French driver, at least, is assured for the Indianapolis race, René Thomas, who won the 500-mile Hoosier classic in 1914. He will drive a Peugeot, as reported by special cable to THE AUTOMOBILE Feb. 17. Resta, DePalma, Pullen, Limberg, Cooper, O'Donnell, Alley, Anderson, Oldfield, Burman, Rickenbacher, Mulford, Rooney and many other first-class drivers are available, so that there should be an abundance of record-breaking speeds registered if the cars can stand the pace these daring pilots are capable of exacting from them.

Contests Scheduled to Date for the 1916 Season

SPEEDWAY RACES

Date	Speedway	Event	Distance, Miles	Purse
May 6	Sioux City	....	......	......
May 13	Sheepshead Bay	Metropolitan Trophy	150	$15,000

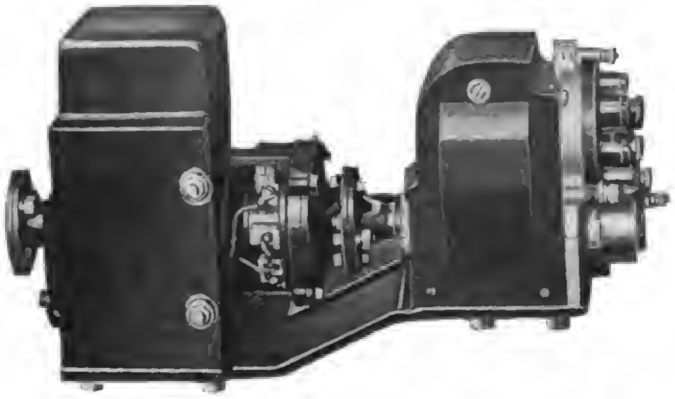
Splitdorf Starting Switch Conserves Current

New Splitdorf-Apelco Two-Unit Starting and Lighting System Incorporates Engine-Speed Generator and Starting Motor with Integral Switch—Uses Constant Voltage Regulation



New Splitdorf-Apelco generator which operates at engine speed, direct-connected to Dixie magneto

A NEW two-unit 6-volt, starting and lighting system has been added to the Splitdorf-Apelco line which incorporates two features of novelty. These are both incorporated in the starting switch and are intended to respectively reduce battery drain and eliminate starting switch troubles.

With the complete Splitdorf system for lighting, starting and ignition there are three units, the generator being intended solely as a means of charging the battery and not incorporating the distributer unit. A separate battery system can, of course, also be used. The installation, as shown in the illustrations, includes a Splitdorf-Dixie magneto for ignition. The layout of a typical system is shown in the wiring diagram electrically, and mechanically the generator and magneto can be operated off the magneto shaft, because it is an engine-speed type of machine.

The important features of the new system are wrapped up in the starting switch design which incorporates a very clever scheme for the purpose of taking the control of the starting motor away from the operator as soon as it has cranked the engine. This is shown diagrammatically in the accompanying illustrations.

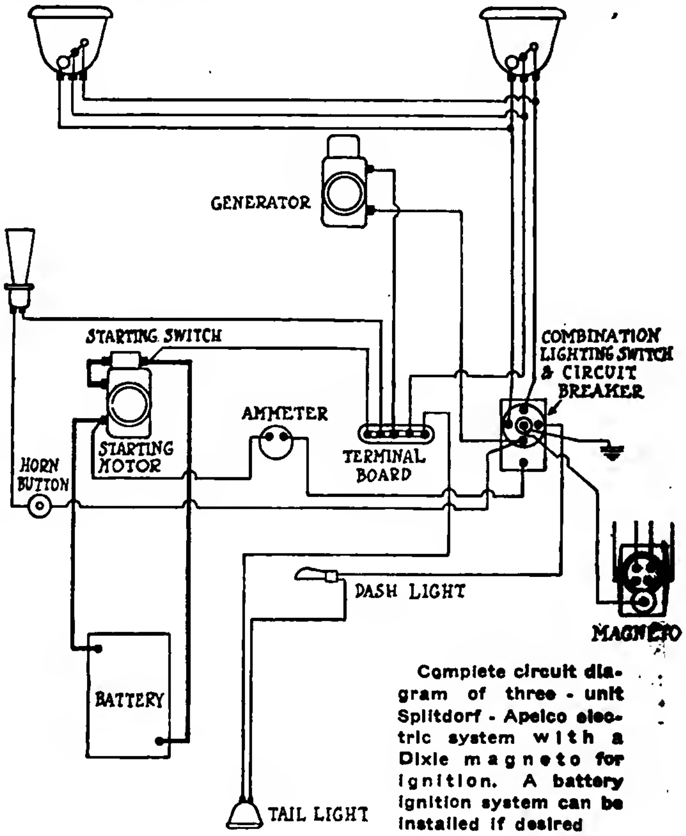
Pinion on Spiral Guide

When the operator presses the starting pedal or button, the mechanical act of pushing on the pedal meshes the starting pinion which slides up into position on a spiral guide. A slight mesh is made mechanically, therefore, in advance of any electrical action. A further movement of the foot closes the contact across the starting switch, which is made up of two independent rods, each carrying a U-shaped contact piece. Contact is made across the rectangular switch box through the two U-shaped pieces which are illustrated in diagram.

As soon as the starting motor has cranked the engine, the motion of the latter throws the pinion back along the spiral sleeve guides. The pinion shaft travels back with the pinion and carries with it one of the two switch plungers, thus breaking the contact, although the foot still remains on the starting pedal. In other words the action of the driver in holding his foot on the starting motor pedal has no effect on the battery, and the starting motor is independent of the driver as soon as the motor has cranked the engine.

The action of the driver in pushing the pedal or pulling the starting lever causes the pinion to be carried into mesh with the flywheel ring gear and when the engagement is made, current flows through the motor as described. As the gear is held movably on the armature shaft, being carried by the spiral guides in a sleeve, these spiral guides tend to hold the pinion in mesh while the engine is being cranked. As soon as the engine picks up, it turns faster than the motor pinion which is engaged with the flywheel, and on account of the spiral splines, the gear is forced out of mesh with the flywheel ring.

The pinion is mechanically connected to a rod which in turn is joined to one of the switch rods in the starting switch. When the motor is first engaged with the flywheel, the switch rod is pulled into engagement by means of the connecting rod and is held in an engaged position under spring tension. As soon as the gasoline engine begins to operate, the gear on the splined sleeve is thrown out of mesh and the connecting rod is forced to its original position. As this rod moves back the engaging latch mechanism is moved to an inoperative position. By this arrangement, since contact is broken as soon as the engine starts to rotate under its own power, the minimum amount of current is used in



Complete circuit diagram of three-unit Splitdorf-Apelco electric system with a Dixie magneto for ignition. A battery ignition system can be installed if desired starting, thus conserving the supply in the battery. The switch contacts are always disengaged with a quick snap to prevent the formation of an arc, thus giving long life to the switch contacts.

Series-Wound Cranking Motor

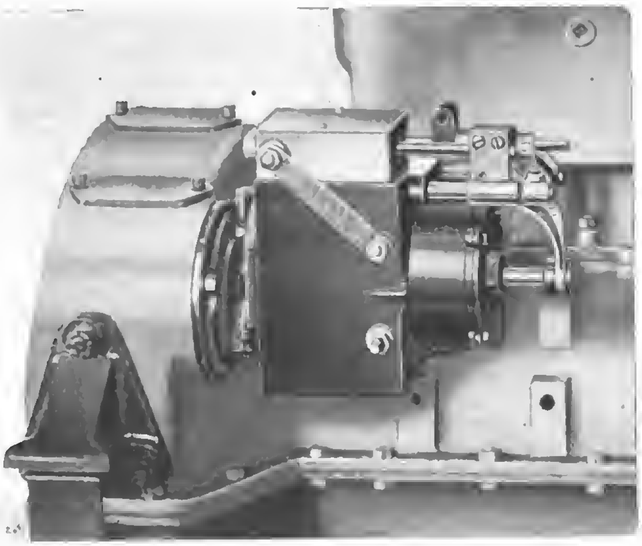
In working out the installation of this system the motor is designed to have a twelve-tooth pinion wherever possible. It is a straight, series-wound machine and, like other parts of the system, can be installed either in connection with a two-wire or grounded return layout.

The generator is shunt-wound and is driven at engine speed. It is arranged to cut in at from 6 to 8 m.p.h. The regulation is a new system of voltage control worked out by the Splitdorf company, so arranged that the current output will not exceed a certain maximum, even though the engine is speeded to its limit. This is accomplished by means of a keeper operated across pole extension. The keeper goes in and out of contact with the voltage fluctuations, responding to the voltage delivered by the generator in proportion to its speed.

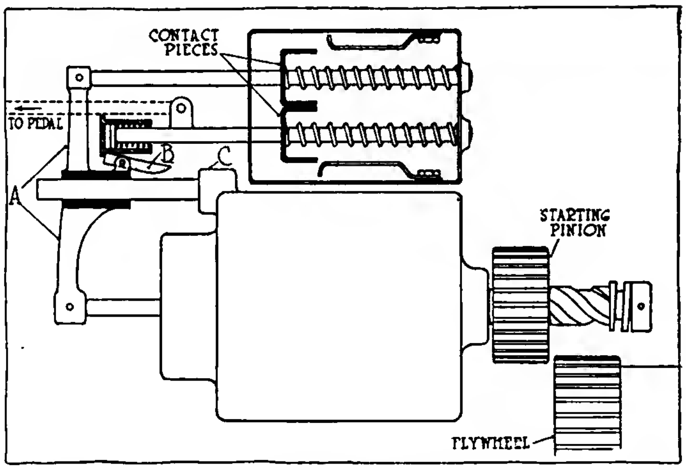
In the construction of the generator attention has been paid to making the job accessible. A movable lid, for instance, is placed over the commutator brushes, so that when the lid is removed the brushes are exposed to view and are readily accessible.

Taking the entire assembly as a whole, this should make a good installation for a car which is started and stopped frequently. The generator cuts in early and also due to its inherent characteristics gives a tapering charge to the battery. If the battery is nearly discharged the generator will put in a larger amount of current than when it is nearly charged; speed conditions being assumed equal in both cases. When the lights are used but little the current is held to a low value, thus preventing boiling of the battery electrolyte.

The regulator is mounted directly on top of the body of the generator and incorporates with it the automatic cutout. On the electric motor the starting switch is carried on the top of the machine, so that the car manufacturer does not need to make any starting switch installation on the car. All that has to be done is to install connecting linkages to give the proper transmission of motion from the starting pedal to the switch.



Splitdorf-Apelco-starting motor showing new switch mounted on top



Diagrammatic view showing the functions of the new switch which is automatically disengaged when the engine starts. Starting pinion flies back and carries with it one of the switch rods through connecting rod A

Six-Cylinder Columbia Well Designed

New Five-Passenger Car to Sell for About $900

HEREWITH appears the first illustration of the new Columbia car produced by the Columbia Motors Co., Detroit, Mich., recently organized and headed by J. G. Bayerline, former president of the King Motor Co.; A. T. O'Connor, W. L. Daly and Wm. E. Metzger. This car is constructed of standard units throughout.

The six-cylinder Columbia touring car which is to sell at about $900

The six-cylinder motor is rated at 21.6 hp., having a bore of 3 in. and a stroke of 4¾ in. The unit power plant includes dry-plate, multiple-disk clutch and a standard two-unit lighting and starting system.

In addition to the above details this car will have Timken axles, front and rear; cantilever rear springs; semi-elliptic springs in front; three-quarter floating rear axle; chrome-nickel steel frame of extra wide section; full-crowned fenders; Stewart vacuum fuel feed; tires, 32 by 3½, non-skids in the rear and the wheelbase is 115 in.

The body is roomy, being of five-passenger capacity. Particular attention is given by the company to the smooth lines of the body and its roominess. The rear seat is 46 in. wide, clear of the upholstery.

Deliveries to Begin June 15

The approximate weight of the car, according to the manufacturer, is 2150 lb. While the price is not definitely announced, it is stated on good authority that it will be around $900. Deliveries of the cars are expected to begin about June 15.

Analyzing Engine Cooling

An Accurate Determination of the Factors Affecting Cylinder Cooling and a Quantitative Examination of Air- and Water-Cooling Comparatively

Results of F. W. Lanchester's Researches Reviewed by A. Ludlow Clayden

IN the last issue that part of F. W. Lanchester's paper was given which deals with the main features of successful air-cooling; and toward the end, the similar major points in water-cooling were touched upon. The paper now continues to discuss this latter subject and goes into considerable detail regarding radiator construction and water circulation. The main thought in this part of the paper is that whether water is used or not we come back eventually to the air, since the water acts merely as a carrier to take the heat from the cylinders and spread it over the radiator where the air can take it up finally. Introducing this subject the paper proceeds as follows:

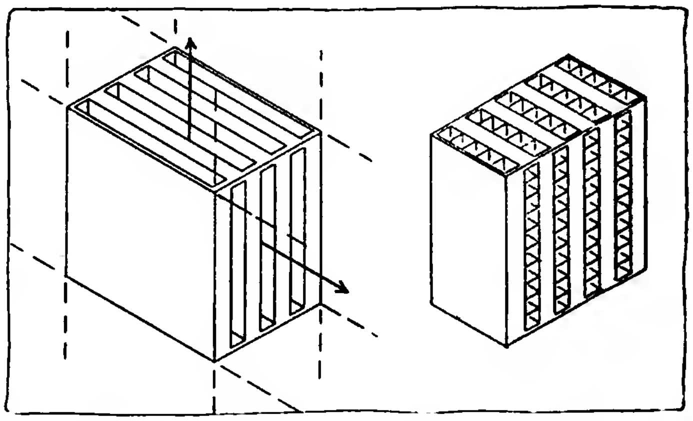
Weight of Water Needed

The conception of a "unit cell" has been put forward as forming the basis of design for the gills forming the cylinder jacket where direct air-cooling is employed; the same conception is equally applicable when discussing the design and proportion of the radiator when water (circulation) cooling is employed; in the honeycomb type the individual tube forms the unit cell. There is, however, one important difference. Whereas in the radiator the individual cell is almost constant as to surface temperature over its whole area, in the air jacket the individual cell has a variable temperature at different points in its surface; the heat per unit area discarded by the different portions of the cylinder wall, and combustion space wall, is by no means constant, the maximum being probably at least twice the mean. But the complication of the problem in the air jacket does not end here; thus if it were required to bring the cylinder and combustion space walls down to some stated temperature it is clear that for a given air velocity the surface would have to be proportionally greater in those regions where the reject heat is greater, and so the value of h (the height of the gill) in terms of s (the pitch of the gills) would need to vary from point to point.

In broad theory it is possible to regard the motor car radiator as a particular case of an appliance for heat transference. It has already been remarked that the various types of radiator may be regarded as analogous to corresponding known types of steam boiler. It would be equally correct to point out that, in some respects and in certain types, the analogy also holds good with the steam condenser; in fact some of the condensers used on steam cars have been almost identical in construction with certain of the coolers or radiators used on petrol vehicles. There are many other industrial uses also where heat transference is required—either a fluid has to be warmed or cooled, or some other purpose fulfilled in which the general principles of cooling are similarly employed.

It is not every type of cooler or condenser, however, or heat transference appliance, that can be said to act on just the same plan as the motor car radiator, since in many cases the flow on opposite sides of the conducting partition is in the same direction and sense or in a sense diametrically opposed. It is a characteristic feature of the motor car radiator that the directions of motion of the two fluids, air and water, are *at right angles one to the other;* there may be other movements in addition to the main motion, but the above salient fact remains.

In its most general form, then, we may regard the type as one in which we have a number of parallel walls in close proximity to one another, with the interspaces alternately coupled to a vertical and to a horizontal conduit, Fig. 13. If the problem were entirely symmetrical as in the interchange of temperature between two different gases at atmospheric pressure, the block of cells or flat tubes would form a square body as drawn in the figure, and owing to the considerations of symmetry the flow of the one gas could be dealt with by exactly the same method as the flow of the other. In the cooling of the internal combustion engine, however, as exemplified by the motor car radiator, the problem is by no means symmetrical; we have on the one hand a liquid—water, 800 times the density and approximately 3200 times the volumetric heat capacity of the air by which it is cooled, and this fact alone has two immediate consequences of importance. Firstly, the thermal continuity between the water and the metallic partition is so perfect that the heat flow from the water into the metal may be taken as free and uninterrupted, whereas the air takes up the heat from the adjacent surface comparatively speaking sluggishly, and so the whole resistance of the heat flux is virtually determined by the air temperature and velocity. Secondly, the *work done* in promoting the necessary circulation of air and water is much greater for the fluid of a lower density, at least this is so in any practical design of radiator so far produced. Thus it is evident that the quantities of air and water per second circulated or passed must be in some degree related to their respective heat capacities, and so the volume of air will be of the order of 3200 times that of the volume of water. But the mass of the air on this basis is four times that of the water (that is, in inverse relation to their specific heats), so that for an actual energy, the respective air and water areas would need to be related roughly in the relation of 6000 to 1. This relation is far, far beyond anything that is possible or expedient, the water channel in practice is commonly some hundreds of times bigger than the above stated, and so it



Figs. 13 and 14—Unit cell conception as applied to water cooling arises that the horsepower absorbed by creating the air blast, that is to say, the fan horsepower (where a fan is used), counts for everything, and the water circulation, so far as power is concerned, for nothing. It will be clearly understood from the above why it is that the area of the circulation pipes, even where convection or "thermo-syphon" is used, is incomparably less than the effective water area of the radiator itself. Thus it comes about that the things which count in radiator design are exclusively those which pertain to the air ducts, namely, the air surface area and the aggregate air duct cross section. We can have higher water velocity, and so a bigger water flux through the radiator for the asking, it costs virtually nothing. We can have the extent of the water surface minimized and the air surface extended by the use of gills, and, within the reasonable limits of conductivity, we lose nothing.

We will consider the radiator for the purpose of the investigations which follow as if it consists of two sets of square tubes laid faggotwise, Fig. 14, that is to say, we will think of the radiator as of the honeycomb type, but in which the water as well as the air is confined to definite rectilinear channels.

Quantitative Analysis of Details

Mr. Lanchester then proceeds to make a mathematical analysis of the air and water flows required to dissipate the required amount of heat, and this being a simple calculation may be omitted from this review. The following are the conclusions reached for the weight of a water-cooling system per horsepower supposing the type of radiator is the most efficient honeycomb form commercially obtainable.

The Condition of Least Weight

The author has calculated the weight of solder in the standard assemblage, and has carefully weighed the tubes concerned. These calculations have been verified by comparison with the makers' weighings of assemblages of 4500 tubes and 3700 tubes respectively, and in both cases the calculated figure and the weighing were found to be within 2 or 3 per cent. In brief, the weight of the solder in these assemblages amounts to 25 per cent of the tubes themselves, and it is actually this proportion of weight which determines, so far as the tube assemblage is concerned, the *length/diameter* ratio of greatest cooling efficiency per unit weight. The fact must not be overlooked that we have an added weight of water which is slightly in excess of two-thirds of the tube weight. Taking this into account, we diminish the relative weight value of the solder in the relation of 5 to 3, and on applying the construction once more we find that the minimum weight proportion comes almost within (but slightly over) the range of lengths used by the makers. We must also take into account the fact that the problem of least weight in the radiator design includes not only the tube block and water content, but also the containing walls including the well and header, and that these are relatively heavier when the tube is longer. It is clear, therefore, that the results reached are in nowise out of harmony with experience as exemplified in present-day practice.

From a quantitative standpoint the actual weight *per square foot surface* of the tube assemblage, analyzed above, is 0.35 lb., and the water weight (per square foot surface) is 0.184 lb. Total, 0.534 lb.

In practice the other portions of the radiator add at least 50 per cent to the tube assemblage or "block" weight, and it is certainly not possible to work with less than 50 per cent addition to the calculated water as contained in the tube block. Thus the total weight *per square foot* surface of this standard type of radiator with its complement of water may be taken as 0.8 lb. For motor car work it is necessary to supply about 3 sq. ft. per horsepower, and thus the weight per horsepower comes out at approximately 2½ lb. This is the present-day tax which the automobile engineer has to pay for his water-cooling apart from the weight of jackets, pipes, pump and their water content.

When we come to the minimum possible for aeronautical work as based on existing practice, we find that the weight per square foot of the tube block is 0.25 lb., and the water content is but little less than in the previous example, approximately 0.15 lb., totalling 0.4 lb. per square foot. This, for a complete radiator with proportionate water charge, becomes 0.6 lb., which is also the radiator weight per horsepower in this case in view of the fact that one square foot per horsepower is approximately the minimum allowance permissible.

It is clear from the above that when the cylinder jackets, jacket water, pump, etc., are included, it is with difficulty that less than 3 lb. per horsepower can be reached in the road automobile, or 1 lb. per horsepower in the flying machine. It is the author's view that in the latter service it will not be found possible, even with the most careful future design and experience, to get below 0.75 lb. per square foot (approximately per horsepower) without the construction becoming too flimsy to stand up to its work.

We pass now to the more complex problem of cooling by gills. We have seen that the distribution of heat over the gill surface is not uniform, and thus in addition to the variation of temperature difference as due to the increase in temperature of the air in its passage through the cell, we have to take into account the variation of the temperature difference as due to the temperature gradient in the gill itself at right angles to the air flow. Now this temperature gradient, as we have already seen, depends upon the conductivity and the sectional form of the gill; thus in Fig. 5 (in which the gill tapers uniformly from maximum at the root to zero at the tip) the temperature gradient is more nearly uniform than in the parallel gill (made from sheet metal of uniform thickness); here the temperature gradient is maximum at the root and approaches to zero at the periphery.

The conditions governing the loss of temperature difference in the line of air flow are (on the assumption of uniform heat emission per square inch of cylinder wall area) virtually the same in the unit cell of air jacket as in the unit tube of the honeycomb radiator already considered. The proximity of the gills, however, in the one problem corresponds to the *radius* of the tube in the other.

Least Weight Proportion

It is evident that in applying a system of unit cells to the cooling of an area of stated measurements, such as a cylinder development Figs. 11 and 12, we may only vary the sectional size of the cells employed; the length is determined by the size of the cylinder and gill distribution adopted, and is therefore constant. Evidently there is some particular proportion that results in a minimum expenditure of copper, in other words a *proportion of least weight.* The investigation which follows is an attempt to determine approximately what this best proportion is under the conditions chosen. For the sake of simplicity we treat the problem as if the cylinder wall were a plane, with the gills normal to the plane and parallel to one another.

Problem Quite Complex

The complexity of the problem of least weight even in its simplest form is great; we must at the outset adopt some convention or make some assumptions as the basis of investigation; without this the number of variables are such that even were a complete mathematical solution possible it would be so ambiguous as to be of but little practical value.

(1) The sectional form of the gill is a matter which must be specified or defined. From the practical engineering standpoint preference might be given to a uniform thickness of material, as, for example, when sheet copper is used. From

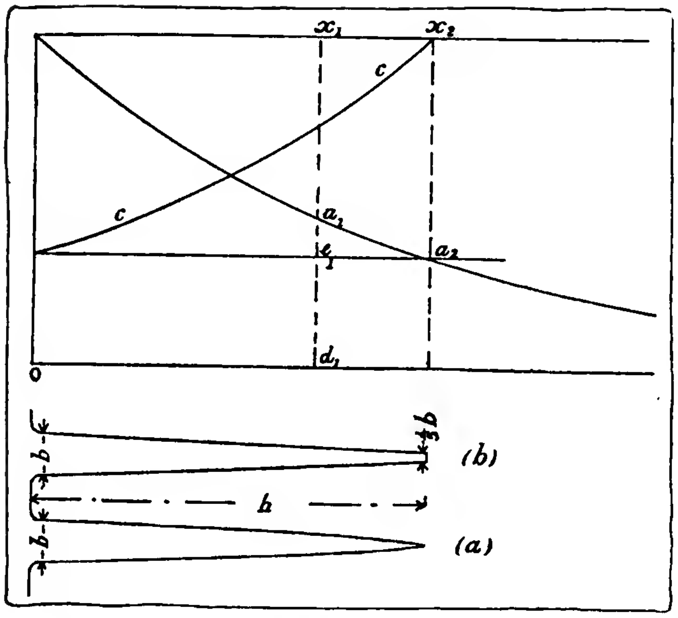


Fig. 15—Curves of temperature difference, and Fig. 16—Ideal and practical gill shapes

a scientific and technical point of view, however, it is better to assume a section giving a logarithmic temperature gradient; a constant value of $\frac{d\theta}{\theta dl}$ in fact. This assumption brings the problem into line with that of the radiator, so far as this particular feature is concerned.

(2) A further assumption which will be made is that the gills are thin compared to the pitch, so that the interspace may be taken as equal to the pitch without serious error. The final result will have to be watched in any case to ascertain that this condition is complied with to a reasonable degree of approximation: an allowance or correction may be needed in the final design if the departure from the assumption be deemed too serious.

(3) Further, it will be assumed that the air flow is based on the condition of some definite available pressure. This is commonly the ultimate fact with which the engineer has to deal. In the case of the flying machine this pressure is the Torricellian pressure corresponding to the velocity of flight, or in *pounds per square foot* is given by expression.

$$\frac{0.5\rho V^2}{32.2}$$

in which ρ is the density and V is the velocity of flight When a fan is employed, the pressure is that in the delivery chest or *wind chest* under running conditions.

Thermal Similarity of Gills

We shall *define* gills as *thermally similar* when the temperatures at different similarly situated points of their height *h* are equal one to the other. The condition above defined when spoken of generally will be termed the condition of *thermal similarity*. Thus under given conditions gills of totally different materials may be *thermally similar* if their thickness is proportioned inversely to their conductivity *k*.

The above definition disposes of any need for the question of conductivity to be taken initially into account. When it comes to a question of design, the gills may be of iron just as well as of copper, provided the assumption (2) above be sufficiently complied with; it is in fact the need for compliance with this condition which will force the designer ultimately to the adoption of the material of highest *k* value available, namely, copper. There is, of course, the additional question of weight saving.

As a preliminary to the investigation, let us examine the exact meaning of the first of the foregoing assumptions, which as it stands might be considered open to criticism.

(1) In Fig. 15, we have a logarithmic curve $a\ a_1\ a_2$ representing the temperature difference, and consequently also the rate of heat loss; abscissae *h* give the height of the gill, and the complementary ordinate $x_1\ a_1$ the area cut off by the ordinate of the curve $a\ a$ at the point a_1. Now the area in question represents the quantity of heat dispersed by the surface up to the point a_1 and if a_2 be the extremity of the gill the whole of the heat will have been given up at that point, hence to the scale of the diagram the ordinate $x_2\ a_2$ will be the measure of the whole of the heat dispersed by the gill in question. Hence the short ordinate, as $a_1\ e_1$ cut off by the abscissa drawn through a_2 will represent quantitatively the heat flux through the gill at every point. Now the heat flux at every point divided by the temperature gradient at that point is the measure of the conductivity, which in the present case is determined by the thickness, so that the appropriate thickness of copper will be at every point proportional to the short ordinate in terms of the full ordinate; at the point a_1, for example, this will be expressed as $a_1\ e_1/a_1\ d_1$. For the particular length of gill chosen this graph is given in Fig. 15, *c c*; this may be taken as defining the gill section, the ordinate scale being many times magnified. In Fig. 16 (a) the gill section is shown drawn to a more reasonable ordinate scale. An approximate equivalent is given (b) of a section more suitable for actual production. The "V" section in practice would never have a knife edge, and the ordinary cast gill complies very fairly with the definition given above.

Weight of Gills

In the following part of the paper full proofs are given for each step in the reasoning. In these pages the proofs will be omitted and the paper abridged very greatly. It will be attempted to retain just sufficient of the reasoning to make clear the steps by which the author reaches his conclusions, and readers who are interested in the detail of the determination are referred to the original paper. It is well worthy of careful study by any engineer desiring to experiment with air-cooling. The consideration begins with the following statement:

Under the conditions of thermal similarity, the aggregate weight of copper for a given wall area is proportional to the square of the height h.

Under the condition of thermal similarity a number of assemblages such as illustrated in Fig. 17 will involve different weights of copper varying directly as h^2 no matter what the degree of sub-division; it remains for us to investigate in what manner the degree of sub-division is independently controlled or determined, and the particular measure of conductivity as a function of h^2 which may be most usefully employed.

Our next investigation will be to determine the best temperature distribution over the gill to satisfy the condition of least weight. That is to say, the best distribution of surface temperature as a standard to which all gills should be thermally similar.

Let us consider a gill of definite weight serving a strip of wall area of definite width, and therefore employed to con-

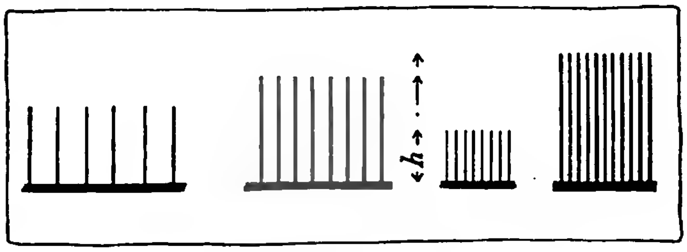

Fig. 17—Possible variations in gill proportions

duct away a certain definite quantity of heat. Let us imagine a number of gills thus all of the same weight but of varying height and varying thickness; our object will be to determine which of these presents a surface to the air current whose combination of area and temperature is such as will dispose of its heat most readily.

We have thus prescribed a gill of constant weight, that is to say, whose section has a constant area; the variations of thickness and height must comply with this condition: we desire to find the particular relation of these quantities when the cooling value of the fin is greatest. Now this condition is that at which simultaneous small infinitesimal variations can be made in the *thickness* and *height*, with no corresponding infinitesimal variation in the cooling value of the fin. Thus we shall suppose the height of the fin increased by a small increment, and we shall find graphically an expression for the corresponding increase of cooling efficiency, ignoring the fact that an increased passage of heat through the root portion of the gill would require a greater temperature gradient. In other words, we may suppose that the increased efficiency is neutralized by lowering the velocity of the air to an appropriate extent.

Next let us suppose the thickness of the gill diminished by all appropriate (negative) increment; to comply with the condition, *weight = constant*. Then the temperature gradient of the gill will be increased and the temperature of the outer portions of the gill will be less than previously, so that in order to carry away the necessary quantity of heat we must imagine the velocity of the air increased.

Condition of Maximum Cooling

*When the increase of velocity required as due to the diminished thickness of gill is equal to the decrease of velocity as due to added height, then we have the condition of maximum cooling effect for a given weight of copper, in other words, we have the condition representing the design of least weight.**

Having ascertained the correct proportion of height to gradient, this proportion settles the thermal pattern to which all gills should conform. We have now to deal with the question of the *sub-division* of the copper distribution; we have already formed the mental picture of an air jacket of thickness equal to the height of the gills and having a definite quantity of copper distributed over each unit area of the cylinder (and head) walls whose weight for any given heat flux density is proportional to h^2. Further investigation is required to determine the extent of the sub-division of the said copper, *i. e.*, the pitch, and thickness, of the individual gills. Our position is as though in specifying the charge for a sporting gun we had settled the weight of lead but had not yet decided the number of pellets.

Cooling and Air Friction

It is evident that if we consider a certain area of wind conduit and think of it first as being quite unobstructed, then we shall have a velocity of air through the said area in accordance with the theorem of Torricelli, but there will be no cooling because there is no frictional surface. If, in the other extreme, we consider the gill assemblage sub-divided to an indefinite extent, i. e., an enormous number of unit cells of minute cross-section, the skin-frictional resistance will become indefinitely great, and there will be again virtually no cooling because the velocity will be negligibly small. Our object is to determine the condition lying between these extremes at which the degree of sub-division is such that the cooling is greatest; with due consideration to any other matters, such as uniformity of distribution, which may be deemed of practical importance.

It is not necessary for us to specify exactly in what manner the frictional surface is introduced into the sectional area of wind conduit under consideration; thus, taking the latter to be 1 sq. ft. and the surface 96 sq. ft., it will make no difference to our present investigation whether the *assemblage* comprises 48 laminæ of 1 sq. ft. area (surface and area 2 sq. ft. each) pitched $s=\frac{1}{4}$ in., or whether 24 laminæ pitched ½ in., with half the individual area, *i. e.*, $l=6$ in. in place of $l=1$ ft. The essential is the l/s ratio, and we may think of either l or s as variable as suits our convenience.

Air Energy Wasted

It may at the outset be remarked that we are not theoretically bound to lose the efflux energy of the air on its leaving the jacket; it is possible by fitting an expanding efflux nozzle to avoid throwing away more than a moderate proportion of the total energy. As a matter of fact, however, the actual conditions are rarely such as will permit of an effective évasé nozzle, and therefore we must be prepared to look upon the ordinary efflux energy as lost.

Now the best way to think of the resistance proper to the Torricellian head is to represent it as so much inevitable and useless friction surface. Thus, in Fig. 18 abscissæ represent the values of l/s ratio, and ordinates represent in the upper diagram percentages of wind velocity, and in the lower diagram percentages of temperature difference. It is clear that for the purpose of this investigation we may take s as constant, so that abscissæ are in effect values of l and therefore represent by their magnitude the resistance of skin friction per square foot conduit area. The abscissa line is shown as carried to the left or negative side of the origin to a secondary origin O_1, and the distance $O\,O_1$ is the length of gill surface to which the resistance of the flux velocity is regarded as equivalent. In cases where it is found practicable to fit an expanding nozzle and so diminish the efflux loss, the distance $O\,O_1$ is made proportionately less. Evidently, also, this distance depends upon the magnitude of ξ selected.* The question of the appropriate skin friction coefficient is one of considerable difficulty. The skin friction double surface coefficient is for the purpose of the present paper taken as = 0.007, this being based on experiment in the open. The author believes this applies also to the gill surface so long as the l/s ratio is low, but there is no doubt that the coefficient is considerably greater for long passages; for example, in pneumatic transmission the basis on which the pipe resistance is calculated corresponds to the value $\xi = 0.016$. In Fig. 18 curves for both these values have been given, the corresponding coefficient being indicated.

Now referring to Fig. 18 the cooling effect will be greatest when the products of the ordinates of the velocity curve and the complementary ordinate of the logarithmic curve has a maximum value. The graph representing this product is plotted for the two values of ξ given in the upper diagram, and the maximum points approximately determined. Now these maxima correspond to an l/s ratio of about 370 and 250 respectively, that is to say, they indicate that the sub-division of the cooling fins should be very fine indeed; and we are at once able to see that in focussing our attention on the maximum we are on the wrong track. If we were to attempt to employ these maximum values we should have a ratio of temperature variation from one end of the cell to the other of 15/100 in the one case and 25/100 in the other; clearly, this is a most undesirable state of things. Our decision in this matter of l/s ratio evidently cannot be allowed to rest exclusively on considerations of maximum efficiency or minimum weight; we have to strike a compromise by selecting a value in which, without sacrificing too far the question of weight or efficiency, we maintain a fairly reasonable uniform temperature difference and arrive at a degree of sub-division which is commercially possible to carry into practice. The matter thus is one of individual judgment, and the author feels that a value in the neighborhood of $l/s=50$

---

*Calculation for gill form follows; omitted here.

* In accordance with the author's practice ξ is the symbol denoting the double surface co-efficient of skin friction.

is one best suited to general purposes, and is the standard, therefore, adopted in the present paper.

Put in another form, and apart from practical or constructional considerations, the argument for rejecting the maximum total cooling value is that, for the sake of a high total value, the cooling valve of the *leeward* portion of the gill is too greatly sacrificed.

The designer may always, however, vary this if he thinks fit, especially if the individual conditions are such as to lead him, in view of all the facts, to suppose that some other proportion is better. Fig. 18, however, stands as his reference diagram whatever conditions he may have to meet.

Degree of Subdivision

It has already been explained that although the variations have been considered as variations of l with s=*constant*, it is equally applicable for variations of s with l=constant, for the factor on which the velocity curves are based is the relation of skin friction surface to conduit area—in radiator terminology, the relation of surface area to frontage area. It clearly is immaterial to the problem what the *scale* of the outfit happens to be except so far as concerning departures from the ordinary laws of fluid resistance commonly used by engineers, that is to say, the resistance varies as the *area* and as V^2 square. Thus, if we have a certain length of jacket and a certain height of gill h and a certain weight of copper per unit wall area, Fig. 18 is definitely the criterion of the degree of *sub-division* desirable.

It is worthy of note that $l/s=50$ gives a loss of temperature difference between the air entering and the air leaving of only 20 per cent with an average or total cooling value approximately half the maximum possible. If $l/s=100$, the loss of temperature difference amounts to 40 per cent and the cooling value obtained is about 75 per cent of the maximum. Under no circumstances does the author consider it would pay to go beyond this.

Drawing the whole of the above facts together we are able to frame a few simple rules for the design of an air jacket.

(1) l is determined from the design. s is related to l in accordance with Fig. 18; ordinarily $l/s=50$ or thereabouts.

(2) The heat flux density for the walls of the cylinder and combustion space is known or is to be computed from the general design and from established test results.

Its mean value is commonly about 13 hp. per square foot; or 2.5 gram calories per square centimeter per second.

The value on the cylinder walls proper is commonly about two-thirds mean value.

The value on the walls of the combustion space is commonly double mean value.

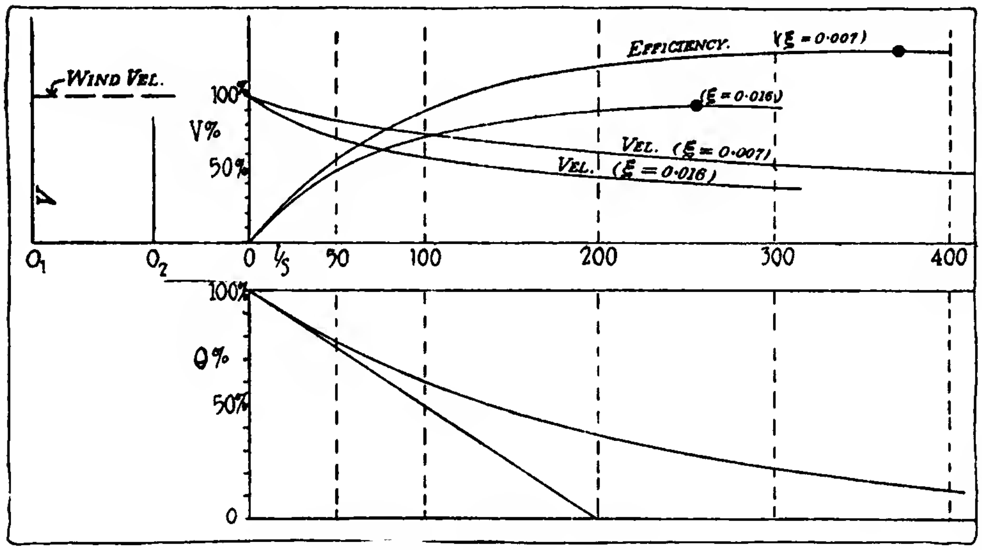

Fig. 18—Cooling efficiency curves

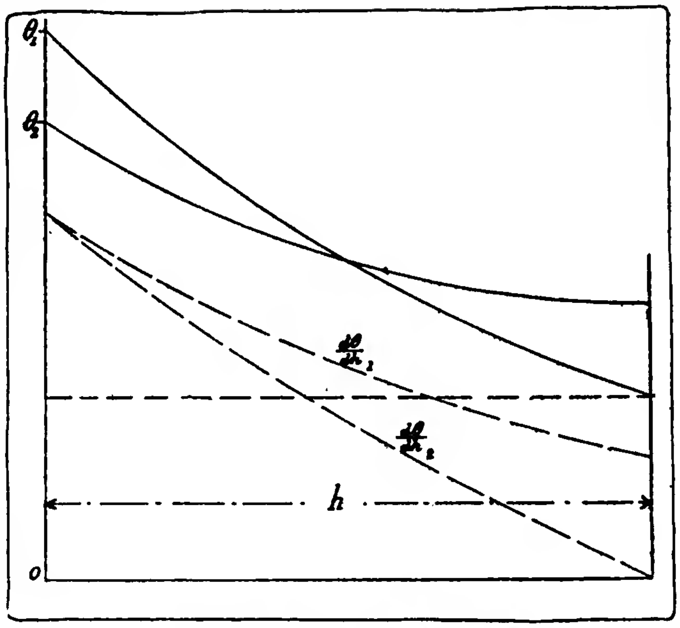

Fig. 19—Curves for gill of rectangular section

(3) The gill surface required per unit area of wall is given by an expression founded on the formula for rate of dispersion

$$\text{hp. (dispersed)} = \frac{\theta V}{15{,}000}$$

Thus,

$$\frac{15{,}000\kappa}{E_1\,E_2\theta V} = \frac{2h+s}{s}$$

In which κ is the heat flux density through the wall, E_1 the efficiency as due to temperature gradient, and E_2 is the cooling efficiency in accordance with Fig. 30. Thus when $l/s = 50$, $E_2 = 0.5$ or thereabouts. Since s is commonly small compared to $2h$ it is ordinarily sufficient to write $\frac{2h}{s}$ in place of $\frac{2h+s}{s}$. This ignores the cooling value of the exterior surface of the walls.

(4) We have thus determined s and h in terms of l. We next have to calculate the root thickness of the gill. From the known heat flux density we calculate the amount of heat discarded by a strip of wall of unit length and width $= s$. The thickness b must be calculated so that the heat gradient

$$\frac{d\theta}{dh} = \theta \times \frac{1.1.}{h}$$

account being taken of the conductivity of the gill material employed.*

Let us take a few examples, basing our cell length l on the considerations discussed, with reference to Figs. 11 and 12. Thus if D be the cylinder diameter $l = 1.6D$. Then,

$$h = 0.14 \times 1.6D = 0.224D$$

$$s = \frac{h}{7} = 0.032D$$

$$b = \frac{h^2}{400} = \frac{D^2}{8{,}000}$$

as exemplified in the following table.

---

*Section omitted.

TABLE I.

D m.m.	h m.m.	s m.m.	b m.m.
60	13.4	1.92	0.045
70	15.6	2.24	0.06
80	18.0	2.56	0.08
90	20.0	2.88	0.10
100	22.4	3.20	0.12
110	24.6	3.51	0.15
120	26.9	3.84	0.18
130	29.1	4.15	0.21
140	31.4	4.48	0.24
150	33.6	4.80	0.28

A comparison of columns 3 and 4 shows at once the importance of high conductivity, especially for cylinders of large diameter. Thus where cast iron is employed in place of copper, b will require to be increased in the inverse ratio of the conductivities, approximately as 1 is to 8; in the case of a cylinder 80 mm. diameter the thickness of the gill would thus absorb about one-quarter of the air interspace, and for a cylinder 150 mm. diameter almost half the space will be taken up. In both cases condition (2) as laid down in Section 55 is infringed; it becomes clear that the successful application of direct air cooling to cylinders of large diameter depends definitely upon the employment of metal of high conductivity.

Turning to the question of weight, we have it from the equation:

$$\text{weight in lb. per hp.} = 0.015\, h^2 \ (h \text{ in c.m.})$$

We may express this in terms of diameter as

$$\text{weight per hp.} = 0.00075\, D^2$$

which give the following values for the series of diameters stated—

TABLE II.

D m.m.	Weight lb. per hp.	D m.m.	Weight lb. per hp.
60	0.028	140	0.15
70	0.037	150	0.17
80	0.047	160	0.19
90	0.061	170	0.22
100	0.075	180	0.24
110	0.090	190	0.27
120	0.110	200	0.30
130	0.125	300	0.67

It is quite clear that with gills as thin as specified in Table I., even in the case of the largest diameter of cylinder, it will be virtually impossible to grade or taper the copper in the manner suggested. Sheet copper, for example, 0.1 mm. thick is already as thin as paper and very liable to be crumpled or injured; any attempt to fine it off, whether by polishing or beating out to a knife edge, is out of the question. It is therefore incumbent upon us to extend the study to include gills of uniform thickness as in Fig. 5. The author has attacked this problem with a certain amount of success, but at present the solution cannot be said to be altogether complete, the mathematical work involved is not easy.

The results so far achieved are given in Fig. 19. Instead of a single form of curve for both *temperature* and *temperature gradient* as when the basis is logarithmic, we have two conjugate curves as in Fig. 19, the curve θ_2 and the lower of the dotted curves $(d\theta/dh)_2$. The curve θ_1 and the upper of the dotted curves are respectively the temperature and temperature gradient curves for a gill of logarithmic properties of equivalent value. It will be noted that the mean of the two curves θ_1 and θ_2 is the same. The uniform gill has been taken of a thickness equal to the maximum thickness of the logarithmic gill; thus the increase of weight of copper is in the proportion of 6 to 10, and the cooling value is the same, but it is to be noted that the gill of uniform gage is doing its work on a far lower cylinder wall temperature than the logarithmic gill, the actual result is that the temperature difference with the gill of uniform gage is 5/6 of that of the logarithmic gill.

It would appear from the above to be sufficient when using gills of uniform gage to design initially for a cylinder wall temperature 20 per cent higher than that intended, and then when substituting the one type of gill for the other the required temperature will be obtained.

Subject Full of Pitfalls

The author says above "*it would appear,*" in view of the fact that the subject is full of pitfalls and the investigation is not yet finished. It is probable that alternatively the cutting down of the gill of uniform thickness to 5/6 of its height as calculated on a logarithmic basis will be good enough for all practical purposes. In this case the parallel gill will involve a weight of copper for giving cooling efficiency about 40 per cent greater than the logarithmic type. Table III gives the results for a gill of uniform thickness on this basis.

TABLE III.

D m.m.	Weight lb. per hp.	D m.m.	Weight lb. per hp.
60	0.039	140	0.21
70	0.052	150	0.24
80	0.068	160	0.27
90	0.085	170	0.31
100	0.105	180	0.34
110	0.125	190	0.38
120	0.150	200	0.42
130	0.190	300	0.95

From tables II and III it is quite clear that the general belief in the greater applicability of air cooling to small engines has ample foundation. Where, as is customary, cast iron is used in place of copper for the gills, the above weights will have to be multiplied by 8 or thereabouts as representing the relation between the conductivities. It is, however, customary to sacrifice cooling efficiency and put up with higher cylinder temperatures to save weight, which would otherwise be excessive, and thus it is that in air-cooled cylinders of about 90 mm. diameter the weight of gills per horsepower in cast iron is commonly only about four times that given in table III for copper.

It is clear that when we run into cylinder diameters of 300 mm. upward direct air cooling offers little or no advantage on the score of weight, but for lesser diameters a substantial saving can be effected. Thus, if we take such diameters as are currently used for aeronautical work—$d =$ 100 or 110—we see that the weight per horsepower is about 2 oz. as against very little less than 1 lb. if water cooling be adopted. There appears to be a clear saving of ¾ lb. per horsepower.

It is the author's opinion that a saving of weight of this magnitude in aeronautical engineering will prove in the future to be quite decisive as settling the cooling system to be adopted; the advantages of direct air cooling are overwhelming. In the case of the automobile the conditions are somewhat different; to obtain an air velocity of 40 meters per second, which is about 130 ft. per second or 90 m.p.h., a fan of considerable power will be needed, and the only fan which would effectively serve the purpose would be one of centrifugal type. It will probably be found advantageous to work with a considerably lower air velocity and a greater weight of copper. The objections are mainly those of noise and horsepower consumed, but with an appropriate increase of copper and a lower fan pressure the saving in weight is still great—probably more than 0.5 lb. per horsepower developed. In the author's opinion, also, there is a possibility of saving cost as well as weight. The main difficulty in the

The History of the American Automobile Industry—23

Two Great Strides of Progress—Compression and the Four-Cycle Principle—Birth of Practical Explosion Type Motor in 1876—Otto's Patent Stimulates Development

By David Beecroft

THIS week brings us to the most important epoch in the development of the gasoline engine. It is the year 1876. To the development of the gasoline engine the year 1876 was as important as the year 1776 to the United States of America. In 1876 the two great steps finally settled in the development of the gasoline engine were compression and the four-cycle system of operation. Compressing the charge before exploding it, which is one of the secrets of the gasoline engine, was made practical. It was patented. For twelve years it had been under consideration. It took this length of time to crystallize how it could best be accomplished. It took several minds to evolve it.

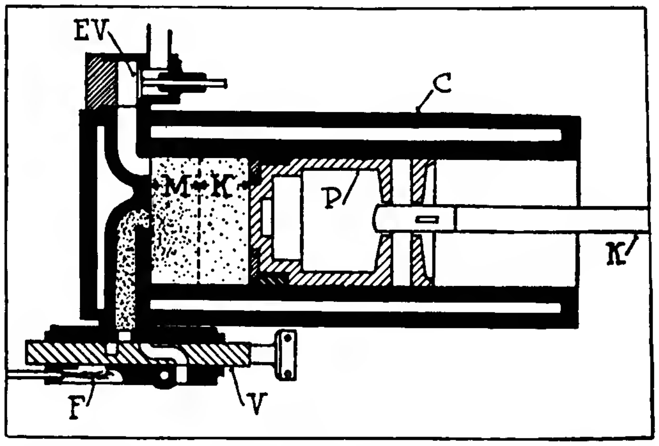
The Four-Cycle Engine

The other great step was the development of the four-cycle engine, operating as our four-cycle engines of to-day, namely: drawing in the charge of explosive gas on the first stroke of the piston, compressing it on the second stroke, exploding it on the third stroke and exhausting the burnt gases on the fourth stroke. All of these cycles were clearly outlined, patented and engines operating on this principle manufactured in 1876.

The year 1876 can best be described as the birthday of the practical explosion type of motor as we have it to-day. The two great basic principles were formulated. It is true that many facts in connection with the engine were not understood; in fact, the inventors had not drifted entirely away from steam. They did not want a sudden explosion as we use to-day, but preferred to have a slow combustion of the mixture so that the expansive force driving the piston was due to the expansion of an air charge rather than to the sudden instantaneous explosion of the charge of gas.

Otto's Early Patent

The name most associated with the development of the explosion engine operating on the four-cycle principle and compressing the mixture before exploding it is Nicolaus August Otto, Deutz, Germany, who on Aug. 14, 1877, was granted patents covering the four-cycle engine and compressing the mixture. His application was made a year earlier. Otto's patent had a very far-reaching effect: in fact, it entirely altered the gas-engine situation and started it on the direct road along which development it is still traveling. It displaced the Brayton two-cycle engine that was then the leader.



1876—Section through Otto four-cycle motor, the father of the present explosion motor. The use of the connecting-rod is noted, also a slide intake valve V, and a poppet exhaust valve EV. The flame ignition is shown at F, and was uncovered by the slide valve at the correct instant for ignition

Although Otto receives to-day practically all of the credit and naturally profited very materially because of his patent, the conception of compression and four cycles of operation was not original with him. He was the person who combined these ideas into a practical engine. The general development of the four-cycle engine as well as the use of compression was twelve years in the making, and three countries participated in evolving the thought. The conception started in 1862, when a Frenchman, Alphonse Beau de Rochas, obtained a patent and wrote a pamphlet in which he laid down the principles of the four-cycle engine. He wrote on the theoretical advantages of the four cycles of operation and of the necessity of compression in order to get thermal efficiency.

Development In England

Six years later the scene of development of the four-cycle compression engine shifted to England, where Boulton, a prolific inventor of explosion engines, secured a patent in 1868 covering the use of compression in an engine. Unfortunately, Boulton failed to work out the necessary means for compression in a practical way, and the net value of his patent was to set more practical inventors thinking along the same line.

In 1874 still another step was taken which unquestionably played its part in the final evolution of the four-cycle engine of Otto in 1877. In 1874 Gilles, an English inventor, introduced the use of the connecting-rod between the piston and the crankshaft as known to-day. Previous to this time the piston rod as used in steam practice had been followed. Gilles' development was essential to the practical working out of the explosion engine.

Coming to Otto's engine, the father of the gasoline engine of to-day, we must understand, before going into a description of the engine, that Otto did not intend to operate his engine exactly as we do. He planned—and his patents show it—first to draw in a charge of pure air during the first half of the intake stroke. During the second half of the intake stroke a charge of explosive mixture was taken in. This drawing of one-half charge of pure air first and mixture later was accomplished by a slide-valve arrangement. Otto's object was to get an expansion from explosion similar to steam. The air charge drawn in first was supposed to fill that half of the cylinder against the piston head. When the explosive mixture filling the outer end of the cylinder was exploded it was expected that the explosion would become slower as it approached the piston head, and that the final part of the power on the piston would be due to the expansion of the air because of the heat of the explosion. Otto, like previous inventors, aimed to get away from the sudden explosion and hoped to get the progressive expansion of steam.

A Single-Cylinder Design

Turn next to a description of Otto's engine taken from his patent papers of 1877.

It was a single-cylinder, horizontal design, with a separate cylinder head and the intake valve arrangement at one side and the exhaust valve at the other side. The cylinder C was open at its inner end, and the piston P is shown with a conventional design of connecting-rod K as invented by Gilles. The intake valve V was a slide one operated by a gearing from the crankshaft. At the opposite side was the exhaust valve EV, a poppet design as used to-day. Ignition was from a constantly burning flame F, and which was uncovered by the valve V at the time when the explosion was desired.

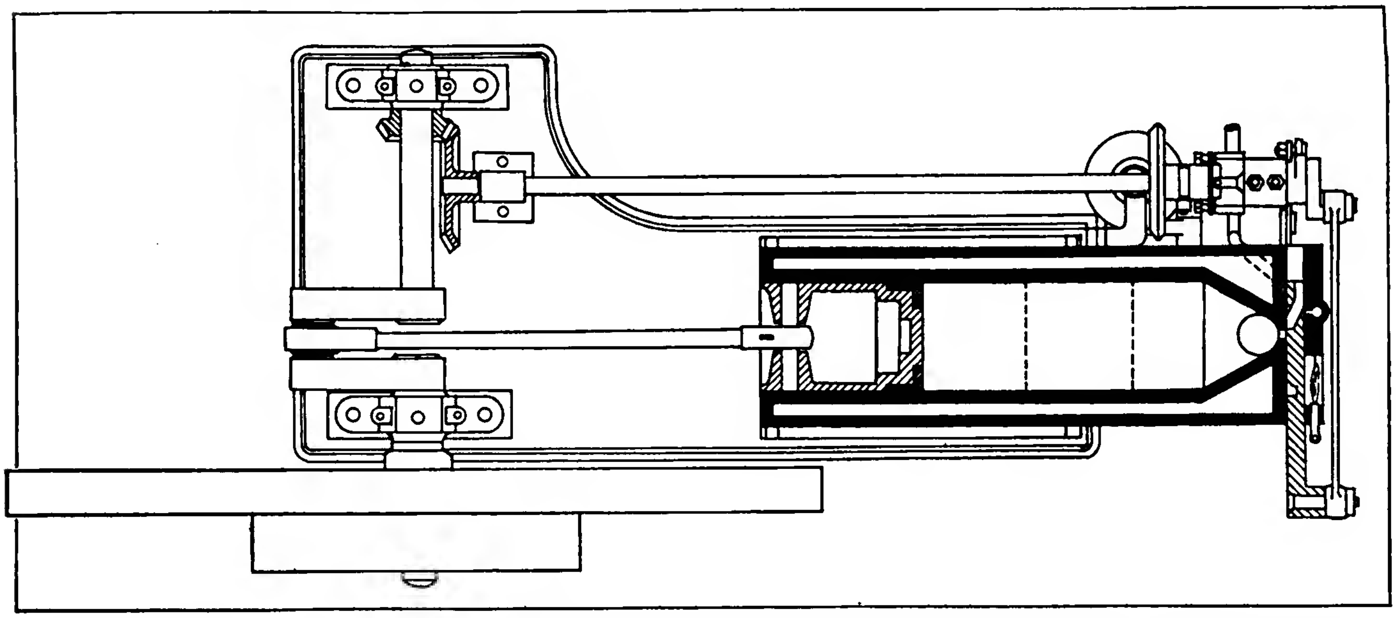
Securing An Air Mixture

In operation Otto had the slide valve V with a passage so arranged as to draw air from the atmosphere during the first half of the stroke, so that that part of the combustion chamber K was filled with air, whereas the outer half M was filled with explosive mixture. Otto realized that during compression there would be a co-mingling of the pure air with the explosive mixture, but notwithstanding this he realized that there would be a quicker burning of the mixture adjacent to the cylinder head because of the greater number of particles of hydrocarbon in that part of it. His conception of how the explosion would take place is shown by the following extract from his patent:

"It will be seen that in this improved mode of operating there is no sudden explosion of the gaseous charge, but a gradual development of heat and expansion of the gases; there will be no such losses of effect as result in gas engines of present construction through shocks produced by sudden development of motor power and by the absorption of heat consequent upon the inability of the gases to expand with sufficient rapidity. This beneficial effect will be further increased by the fact that the charge of air interposed between the combustible mixture and the piston will operate as a cushion or buffer in still further reducing the suddenness of the expansive force generated as it transmits it to the piston."

Otto had a very clear conception of all the requirements of valve timing as necessary for the

(*Continued on page* 615)



1876—Part section through Otto's four-cycle engine, the first one made to operate on the four-cycle principle. The slide valve is placed transversely on the cylinder head. Thus the first four-cycle motor was a valve-in-the-head design. The use of a connecting-rod was new, having been patented but two years earlier

The FORVM

ADVOCATES AIR COOLING—SIZES OF TRUCK ENGINES AND FORMULAS INVOLVED—A CAST BRONZE CYLINDER FOR AIR COOLING

Air-Cooling Most Satisfactory

By H. A. Grant
(Chase Specialty Co.)

THE article on engine cooling in the March issue, and your editorial in the same issue, are very much to the point, and I have been surprised that this matter has not been taken up by automobile engineers in this country long ago. Having been associated with the automobile business since 1905, and having owned some nine different makes of automobiles in that period, I appreciate both the article and the editorial.

I have yet to learn of a single objection to air-cooling, and I can put my finger on several very distinct advantages. It has sometimes been stated, as an objection against air-cooling, that practically every concern that used to employ it has either failed, or abandoned it in favor of water-cooling. This argument is no argument, for several of the concerns that first tried air cooling, and then water cooling, made an equal failure of both. Then again, I think everyone will admit that in the early days at least, we patterned as closely as possible after the foreign cars.

Reasons for Water Cooling

There are many reasons that have led to the almost universal adoption of water-cooling, probably the chief reason being that new manufacturers entering the field choose to follow the course of least resistance. Consequently, there was much available data on water-cooling which enabled new manufacturers to build what they had every reason to believe would work satisfactorily, since it followed common practice.

The problem of air-cooling was one which no one, with the exception of the Franklin Automobile Co., knew anything about. Yet, to-day I believe that the Franklin cars have the most perfect system of cooling, either air or water, that we have.

The various cars that I have owned, both low-priced and high-priced, have given me a pretty clear idea of what I want, and what I do not want, and when I began to canvass the market last spring with another engineer, it was with the idea of selecting as nearly perfect an all-around machine as possible.

Air Cooling Tested

With practically a year's experience with the Franklin, I have no hesitancy in saying that it is by far the best all-around machine I have ever owned. Its cooling system leaves nothing to be desired. I have purposely subjected its air-cooling system to the most extreme tests, and yet never have I been able to find the least trace of overheating. On the other hand, being designed to work at a temperature of 350 deg., it has shown the greatest economy in gasoline, averaging for the season slightly over 19 m.p.g., and frequently averaging, under favorable conditions, as high as 25 m.p.g.; this with a six cylinder touring car carrying five people. I feel that such results speak for themselves, and show the possibilities of direct air-cooling when worked out the way the Franklin people have solved the problem.

Truck Engine Sizes and Formulas

By John Younger

THE paper read by W. D. Williamson before the I. A. E. brings up again the question which time and progress are now settling. There seems to be an idea prevalent that truck engine sizes need be bigger in this country than in Europe, and Mr. Williamson throws no additional light on the subject.

In 1913 C. T. Myers gave a paper before the S. A. E. to establish a formula for engine capacity:

$$TF = \frac{28.22 \times d^2 s R}{D W}$$

Where TF is a tractive factor

$$\left.\begin{array}{l} d \text{ is diameter of cylinder in inches} \\ s \text{ is stroke of cylinder in inches} \end{array}\right\} \text{the usual 4-cyl., 4-cycle engine is assumed.}$$

R is total gear reduction
D is diameter of driving tires in inches
W is gross weight of vehicle in pounds

For reasons stated in his paper, he gave the value of TF as being 0.04 for good practice, European trucks being slightly less, and American trucks being then somewhat more.

In another form he stated that $\frac{d^2 s R}{D W}$ should equal 0.0014. (a)

Williamson's Formula

Take now Williamson's formula:

$$Q = \frac{V}{W} \qquad \text{(b)}$$

Where V is volume of one cylinder in cubic inches
W is weight of vehicle in *long* tons.

All his trucks are assumed to go 15 m.p.h. with an engine speed of 1300 r.p.m., so that approximately, $R = \frac{12}{\pi D}$

Substituting this in (a)
we have

$$\frac{\frac{\pi}{12} d^2 s}{W} = 0.0014$$

or

$$\frac{\frac{\pi}{4} d^2 s}{3 \times 2240\, W} = 0.0014$$

or

$$\frac{V}{W} = 9.4 \qquad \text{(c)}$$

This is in exceeding close agreement with Williamson's

9.3, and is rather wonderful, considering the premises and method of attacking the problem are quite different.

Thomas' Formula

Williamson's formula is somewhat involved and to my mind a simpler formula can be devised.

H. K. Thomas uses this formula for the capacity of a truck:

$$\frac{63{,}000\,PRe}{n\times\frac{D}{2}\times W\frac{[20g+r]}{2000}}=1. \qquad \text{(d)}$$

Where P is horsepower at engine and "w" r.p.m.
R is as before
e is mechanical efficiency of transmitting mechanism
W is weight of vehicle in pounds.
g is percentage grade.
r is road resistance in pounds per 2000 lb.

By stating what you definitely expect a truck to do you can find the value of P, and hence V. My practice, and I find it acceptable, is that a truck should climb a 3-per cent grade on high gear with a road resistance of 50 lb. per ton, with practically no falling off in a speed of about 15 m.p.h.

Its e should be 0.85.

Personally, for many reasons concerning not only the engine, but the whole vehicle, I think a governed speed of 1000 r.p.m. preferable, and I do not limit the speed of 15 m.p.h. to light trucks, but carry it up to 5 tons capacity.

The gear ratio R then becomes $\frac{\frac{\pi}{12}D}{1320}$

So that we have

$$\frac{63{,}000\,P\times 0.85\times\frac{1000}{\frac{\frac{\pi}{12}D}{1320}}}{1000\times\frac{D}{2}\times W\left[\frac{60+50}{2000}\right]}=1.$$

or

$$\frac{38.6\,P}{W}=1.$$

Now P at 1000 r.p.m. with an $n\,p$ of 80 lb. per square inch is 4.85 V
and $W=2240\,W$,
so that

$$\frac{38.6\times 4.85\,V}{2240\,W.}=1.$$

or

$$\frac{V}{W}=12.$$

This is obtained with an engine speed of 1000 r.p.m. Correcting this to Williamson's 1300, 12 would reduce in inverse proportion to $\frac{1000}{1300}\times 12$, giving us again the figure $\frac{V}{W}=9.3$, also in remarkable accordance with the others.
cordance with the others.

In its simplest form we may take it that a motor truck for use in any country should be just capable of climbing a grade of 3 per cent on high gear at full motor speed, against a road resistance of 50 lb. per ton of 2000 lb.

The motor capacity should be such that

$$\frac{\frac{V}{W}}{2240}=12\times\frac{1000}{n}$$

or

$$\frac{Vn}{W}=5.36. \qquad \text{(e)}$$

Where V is volume of one cylinder in cubic inches
(a four-cylinder four-cycle engine being assumed)
n is normal number of revolutions of engine
W is gross weight of vehicle in pounds.

In connection with the above, it is somewhat interesting to note that H. K. Thomas introduced a coefficient Q in 1913, as a standard of comparison between different vehicles, trucks and pleasure cars.

This Q is really a measure of piston displacement per foot traveled per 1000 lb. gross weight, as will be seen from the formula:

$$Q=\frac{\frac{\pi}{4}d^2 s\,n\,R}{\pi\,\frac{D}{12}\times W.}$$

n is number of cylinders
W is gross weight per 1000 lb.

This reduces to the simpler form.

$$Q=\frac{3\,d^2 s\,n\,R}{DW} \qquad \text{(f)}$$

This coefficient is of great value and has been adopted as a standard of comparison by the combined engineering departments of the Pierce-Arrow Motor Car Company.

It gives an indication also of the relative gasoline consumption of the different vehicles.

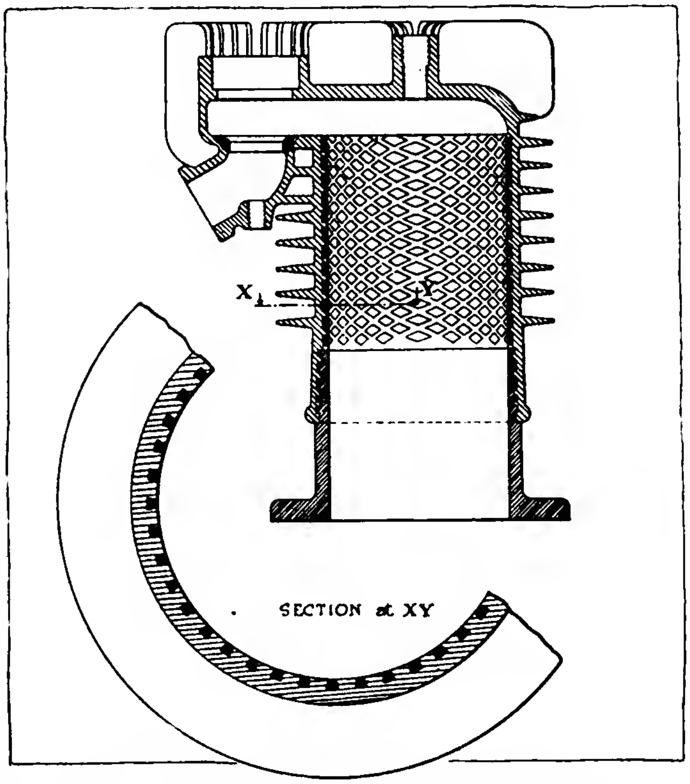
A Bronze Alloy Cylinder

By L. G. Nilson

(Nilson-Miller Co.)

YOUR article and editorial on air-cooling in THE AUTOMOBILE for March 16 indicate interest in this subject. In 1911 I obtained a patent, No. 1,010,787, covering a cylinder construction designed to combine light weight and efficient air-cooling by the use of a manganese bronze or similar alloy cast around spirally-arranged wearing pieces of cast iron having undercut grooves so that the bronze will flow into these and tightly fasten the wearing surfaces. In one sense the cast iron cylinder is a lining for the bronze cylinder. One operation suffices to unite the two cylinders since the iron cylinder is grooved on the outside so as to present diamond shaped lugs to the bronze coating, which, if applied before the bronze is cast, prevents the cylinder from rusting. As shown in the illustration, integral radiating flanges are cast around the top and sides of the cylinder.

The base of the cylinder may be a cast iron if desired as it is not subjected to heat, but where light weight is desired the entire cylinder may be of bronze or other alloy.



Nilson patent cylinder construction using bronze or other copper alloy for light weight and air cooling

The Rostrum

Petromortis Experiences

EDITOR THE AUTOMOBILE:—Reading so many discussions and noting queries regarding carbon monoxide poisoning, think perhaps the following personal experience will enlighten some of your readers.

In 1903 I owned a one-cylinder Packard with 6-in. bore. I overhauled same during the winter and was tuning the car up in a fairly light garage, 16 by 22, 9-ft. headroom. It was on a very cold winter night and a coal fire was burning in this room. The motor had been running about 15 minutes, when, without any previous warning or the slightest discomfiture, I remember reeling and falling. I do not recall striking the floor. As I was falling I saw my brother, who was with me, falling also. The motor was still running when we became unconscious. We both owe our lives to the fact that I happened to be passing by the door and I believe that in falling struck the latch, opening the door, for when I regained consciousness, I was lying partly out of the door in the snow. I managed to drag my brother out and he shortly regained consciousness.

We both suffered intensely from headaches and violent heart action. Arteries in the neck distended at each heart beat until it seemed they would burst. I remember my brother's temples pulsating with at least ¼-in. movement. My wife, alarmed at our non-return, found us as we were becoming able to stand, and procured some aromatic spirits of ammonia which helped us. The ill effects lasted nearly a week.

This all occurred in the early days of the gasoline automobile and before the automobiling public had been acquainted with this insidious gas. Too much care cannot be exercised. I know of one case at least where the victim worked on his car expecting to be warned by some indications or discomfiture in time to stop, but his experience was similar to mine. No warning was given.

Brighton, Mass. C. F. SMITH.

Using Mixed Fuels

Editor THE AUTOMOBILE:—Where can I secure information regarding any recent tests on the use of alcohol, benzol and keresone as motor fuels and also a fifty-fifty mixture of alcohol and benzol and kerosene and gasoline?

2—What is the amount of heat it is necessary to supply for the various fuels; what changes are necessary in float mechanism and jet sizes; also whether special fuel is required for starting or whether an electric heating device could be used to be operated from starting battery?

Detroit, Mich. L. E. F.

—It is impossible to answer these questions in definite terms, as everything depends upon the particular motor under consideration, and even at that there is no readily available collection of data. A fifty-fifty mixture of alcohol and benzol almost invariably acts exactly like good gasoline, requiring no alterations of any kind. Kerosene and gasoline when mixed will act well in a motor which has a carbureter giving a very fine spray and with an extremely short intake manifold or else a manifold jacketed with hot water or exhaust gas. The addition of kerosene will call for slightly more air.

2—It is possible to start on mixtures of kerosene and gasoline in warm weather without special heating, provided the carbureter atomization is sufficiently fine. An electric heating device operated from the starting battery has been applied for the purpose of warming the nozzle and this greatly assists starting. As a rule, with an ordinary carbureter it is not possible to get satisfactory running with a mixture so rich in kerosene that starting requires a special supply of lighter fuel.

Spectroscope for Carbureter Testing

Editor THE AUTOMOBILE:—Could you give me some information concerning a spectrescope such as aeroplane manufacturers use in testing their motors to tell whether they have the best explosive mixture for their motors?

2—Where could I purchase one?

Greenwich, Conn. L. H. M.

—A spectrescope can be purchased from any dealer in scientific instruments, but it is a rather elaborate and costly piece of apparatus for determining carburetion.

Timing Six-Cylinder

Editor THE AUTOMOBILE:—Please explain how to time a six-cylinder motor. The magneto was taken off some time ago and the motor has been turned over. How must I set the motor and magneto so that they will fire right?

Ames, Iowa. N. D. B.

—To time a 6-cylinder motor remove the distributer cover so that you can see the carbon brush of the high tension distributing arm. Set the piston in No. 1 cylinder until it is exactly at the top of the compression stroke. Turn the armature of the magneto until the distributer brush touches the segment corresponding to No. 1 terminal on the magneto. Then move the armature more gently while examining the low tension end until it is seen that the break is just about to take place. If you then attach the magneto while in this condition you will note that the break will occur and the spark take place just as the piston is coming over dead center, which is correct for full retard. With a fixed spark magneto the setting would have to be made with a piston about ½ in. or even more below the dead center and on the rising side. You will probably find it advisable to get an approximate setting to run the engine and then try advancing setting one tooth. If the motor lacks power it means the magneto is too much retarded. To make quite sure you have the distributer set correctly follow the firing order of the cylinder so as to check this, and then see that the high tension wires are in proper sequence on the cylinder.

Simple Hydrometer

Editor THE AUTOMOBILE:—Replying to the letter of H. M. B. in your issue of Feb. 7, relative to testing a mixture of denatured alcohol and water to ascertain its freezing point, I beg to state that there is a simple hydrometer on the market which is graduated so as to indicate the freezing point of a mixture of denatured alcohol and water. To make the test it is only necessary to draw off a small portion of the water from the radiator into the containing vessel, float the hydrometer in this and read off the freezing point. I have used an instrument of this nature several years and have found it entirely satisfactory. The hydrometer is made by the Alcohol Utilities Co. of New York.

South Bethlehem, Pa. BARRY MACNUTT,
Lehigh University.

Putting Ammeter on Buick C 25

Editor THE AUTOMOBILE:—Kindly give sketch and directions for installing an ammeter reading scales 15 to 0 to 15 on a 1915 Buick model C 25.

2—What size wire should be used?

Schleisingerville, Wis. J. K.

—The accompanying illustration, Fig. 1, shows the method for installing an ammeter.

2—H-10 wire should be used.

Limiting Engine Speed

Editor THE AUTOMOBILE:—There seems to be some misunderstanding regarding the maximum r.p.m. of high speed automobile engines, but more particularly the eights and twelves. I, and no doubt many others, should like to have correct information concerning the highest speed yet obtained, and the theoretical top speed of an engine of the ordinary reciprocating type.

This letter is occasioned by an argument I had with a salesman at the Haynes stand in last week's Boston Automobile Show. On questioning him about the maximum speed of his twelve-cylinder engine, he informed me that it was 4340 r.p.m. I argued that the motor would not operate at that speed because there would not be time to draw in gas, fire it and exhaust it; and that the valve would not have time to close at so high a speed. He claimed that the valves had to operate regardless of the engine speed. Then I asked what limited his engine speed. He replied that there was no limit and that the r.p.m. would go to 5000 or even 6000 if the designing engineers had wished it so.

Furthermore, when recently talking with a very intelligent mechanic who works in the local Cadillac agency, I was informed that the Cadillac, when it recently averaged 70 odd m.p.h., on a speedway, had an engine speed of over 8000 r.p.m. He had not stopped to figure out the speed, but was simply taking someone's word for it. Consequently, I figured out the engine speed and convinced him that the r.p.m. were somewhat below 4000.

I have understood that Prof. David L. Gallup, who is head of the gas engineering at Worcester Polytechnic Institute and a prominent member of the S. A. E., got the highest speed thus far obtained from an automobile engine. That is, he speeded up a Flanders 20 engine to over 4000 r.p.m. before it ran dead.

Nashua, N. H. G. C. H.

—Internal combustion engines of small size have been made to run and deliver power at speeds up to 6000 r.p.m. A good modern automobile motor of the highest speed type will run at 4000 r.p.m., delivering maximum horsepower at about 3000. It used to be thought that it would be impossible to get gas into a cylinder and to fire it for speeds as high as this, but experience has proven the theory to be wrong, which is another way of saying that an engine will run on a very small charge.

Value of Oversize Tires

Editor THE AUTOMOBILE:—I have a Dodge touring car, which I practically always run loaded with five people. Under these conditions would it be advisable to use oversize tires, 33 by 4 regular 32 by 3½?

2—Is the actual air cushion in 33 by 4 larger than in 32 by 3½?

I understand that 32 by 4 is actually larger than 33 by 4.

3—In the *Forum*, March 3, article by Charles E. Manierre, working table is given to inflate 4-in. tire to 60 lb. for 750 lb. load per wheel. Would this hold good for 33 by 4? Somehow I have the impression that 33 by 4 has not the air capacity it is supposed to have.

Wonalancet, N. H. E. L. F.

—It is almost always best to use oversize tires.

2—Yes.

3—Yes.

Adjusting Buick Valves

Editor THE AUTOMOBILE:—Kindly give me a description of a Buick 1912 model 29, telling how to adjust the pushrods on this car. I have trouble starting this car and have been told that the carbureter is not adjusted properly, and when it is adjusted to suit starting the engine it misses. Kindly give me necessary instructions.

Baltimore, Md. E. McI.

—The pushrods can be adjusted by loosening the lock nuts and yokes which fasten them to the rocker arms. These rods should be adjusted with a clearance of 0.010 in. between ends of valve stems and rocker arms, when both valves are fully closed.

It is quite probable your trouble in starting is due to too much clearance on the pushrods. If the valves are not operat-

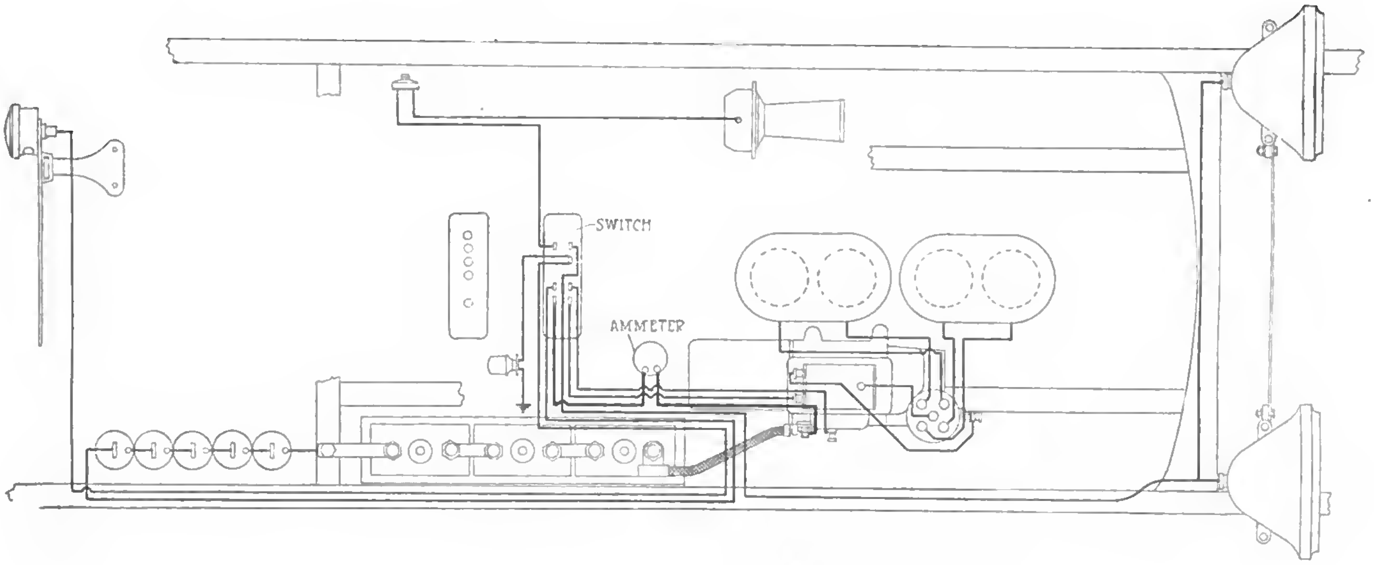


Fig. 1—Position of and connections for fitting ammeter to Buick 25

ing correctly you will need an excessively rich mixture for starting.

Series Plugs Cannot Hurt Engine

Editor **The Automobile**:—I have a Scout 1914 model American underslung with a four-cylinder 4 by 5 motor, T-head type, which I have recently equipped with double ignition by using two spark plugs in series for each cylinder. Since making this alteration it has occurred to me that possibly I have been unwise as the much more rapid combustion due to the two-point ignition might subject the engine to greater strains than it was designed for, especially at low speeds.

Equipped with series plugs there is no way to cut out one set while running at low speeds and then to cut them in when the faster speeds are attained.

Will you please inform me whether you deem it advisable to discontinue their use?

San Antonio, Tex. C. M. B.

—It is highly improbable that you would injure your motor by using two-point ignition. As long as the engine does not knock when running slowly no harm can possibly accrue. It certainly would be possible to design a cutout switch for the second plug but it would not be very simple as it would have to be a high tension switch.

Wiring of Saxon

Editor **The Automobile**:—Through the columns of the Rostrum would you give me the complete wiring diagram on the Saxon S-2 touring car, also how would you go about to take the Atwater Kent timer off so as to get the cylinder head off to clean the pistons and get the timer back in its place so it will be in time?

Marshall, Ill. E. F. C.

Wiring diagram of the model S-2 is given in Fig. 2. To remove the Atwater Kent distributer, it is only necessary to loosen the set screw which holds it into the bracket. You will notice after having removed the distributer that the driving slot in the shaft is off center. The distributer cannot be put back into place and be out of time.

Two-Point Ignition for Power

Editor **The Automobile**:—I have a Chalmers car model 26-B in which the engine is too small for the weight of the car for satisfactory use over our rough and trying roads. I have read several times of the increased power secured by the use of the two-point sparking system as obtained by the use of the Su-Dig plugs. Will you kindly advise me if I could obtain increased power by drilling and tapping the caps over the exhaust valves in this car and using the two-point plugs, and if it would be liable to injure the balance of the ignition system, which is of Atwater Kent make with current taken from a nine-cell battery?

Dowagiac, Mich. A. B. G.

—You would probably obtain slightly increased power with a two-point sparking system and need not have the least fear in applying it, as it could not injure the ignition system.

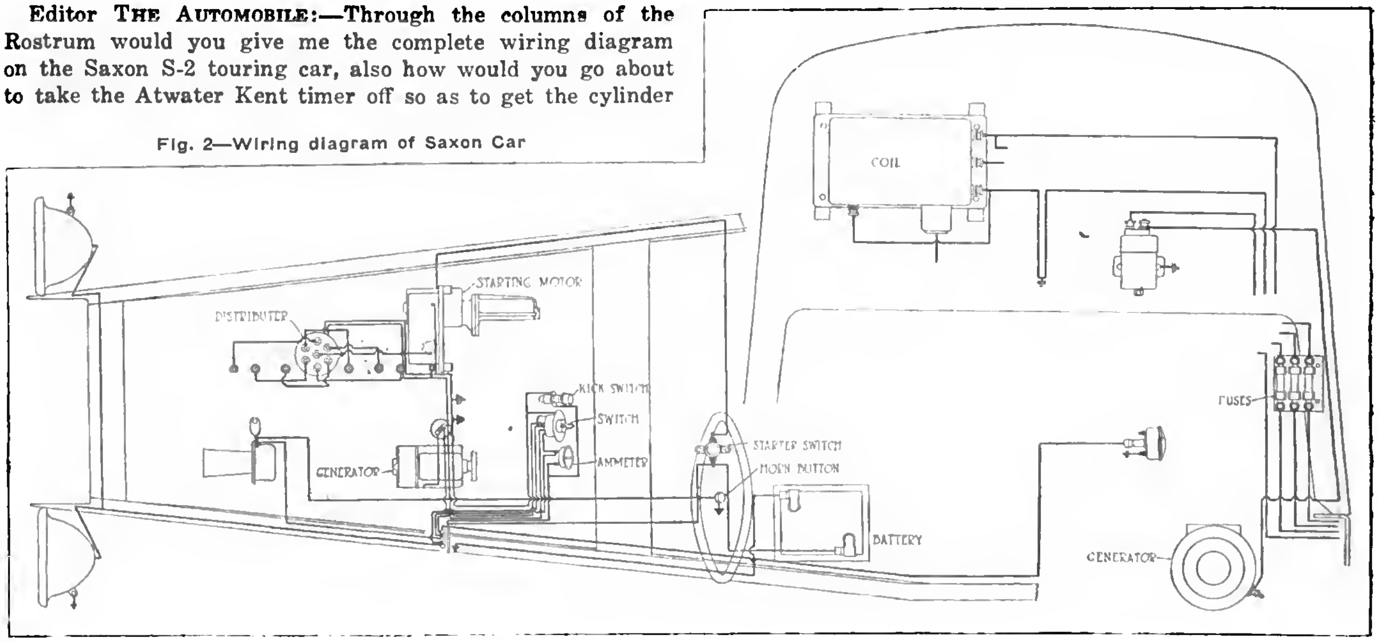

Fig. 2—Wiring diagram of Saxon Car

Analyzing Air Cooling

(*Continued from page* 591)

case of the ordinary motor car is that of properly accommodating the fan and air conduit arrangements; in this respect the ordinary motor car does not lend itself so well to air cooling as does the flying machine.

Sooner or later a limiting diameter must be reached at which the weight of copper becomes prohibitive in face of the possibility of cooling by water circulation, but the reservation must always be made that the foregoing figures are based on assumed distribution of air jacket gills. In special cases it may be found possible to sub-divide the jacket in the manner, for example, illustrated in Fig. 9.

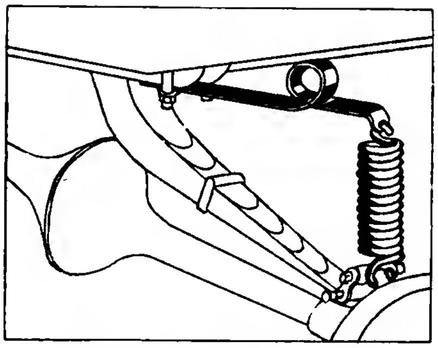
It will probably be found that the weight per horsepower is independently limited by considerations of an entirely practical nature. Thus, copper of less than 0.01 in. (0.25 mm.) is so structurally weak and flimsy that the limit of what is actually available is evidently in that region. The thinnest the author has employed has been nearly double that figure. If we accept a limit of thinness in this region, the weights per horsepower given in table III for cylinders of less than 140 mm. cannot be realized to the full; it would seem, in fact, that the weight per horsepower will automatically remain the same for all cylinders from 140 mm. downward. The simplest course when dealing with cylinders of less than 140 mm. (which, after all, includes the majority of cases) is to adopt the gill standard proper to that diameter uniformly on all sizes; if this be done the design of the air jacket may be finally specified (for copper) in the following form:

b (copper) 33s.w.g. = 0.01 in.
s 4.5 mm. (= 5.5 per inch)
h 26 mm. (for uniform thickness) say = 1 in.

ACCESSORIES

Burrows-Overton Shock Annihilators

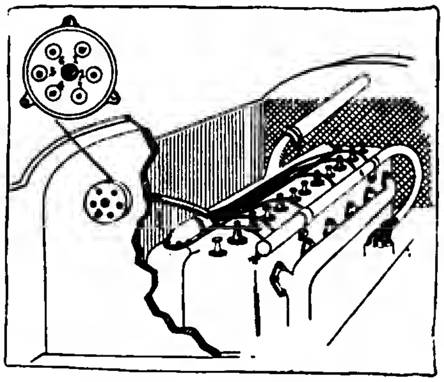
CONSTRUCTED on the spring-lever principle, the Burrows-Overton device for the rear of Ford cars is claimed to control to the fullest extent all side-sway and rebound. The top bar is made of 1 by 3/16-in. flat spring steel and has a coil of 2-in. diameter in it which renders it exceedingly flexible. This is attached to the frame cross member and is secured in place by a U-clip and yoke and also by a right-angle upturn of ½ in. at the inner end. A rectangular wooden block prevents the bar from slipping up into the spring channel. The expansion spiral spring hooks to the brake drum bracket with a specially-designed hook, slipping easily into place. The whole device can be mounted on the car in five minutes, according to the manufacturer, without disconnecting any part of the car. The shock annihilators sell for $3.50 per set of two.—Burrows-Overton Co., New York City.



Burrows-Overton Shock Annihilator

Lazco Trouble Detector

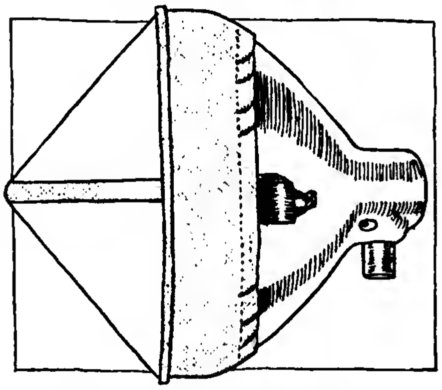
A series of spark gaps is arranged in a round casing mounted on the dashboard. There is a point for each spark plug of the motor and a central point connected with the other side of the circuit. Opposite each point there is a window. An arm, which may be turned in a circle by an exterior knob, may be brought opposite any of the points; if the engine is being properly ignited, it will be indicated by the spark at the gap. Price for fours and sixes, $5; eights, $7.50, and twelves, $10.—Lazarus Mfg. Co., Cleveland, Ohio.



Lazco ignition trouble detector

Clark Headlight Dimmer

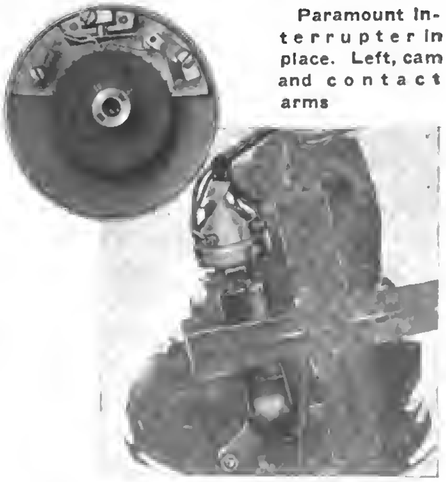
In this device a cone of pyralin is attached to the front of the lamp by means of a flexible band which fits tightly over the rim. The light is diffused and scattered in all directions. When not in use, the dimmer is folded flat and can be put in the pocket or under a seat cushion. No. 1 is for lamps up to and including 9½ in. outside diameter, including Ford lamps; No. 2 is for all lamps larger than 9½ in. No. 1 sells for $2.50 per pair and No. 2 for $2.75 per pair.—Cherry-Clark Guard & Dimmer Co., Chicago, Ill.



Clark flexible folding dimmer

Paramount Interrupter

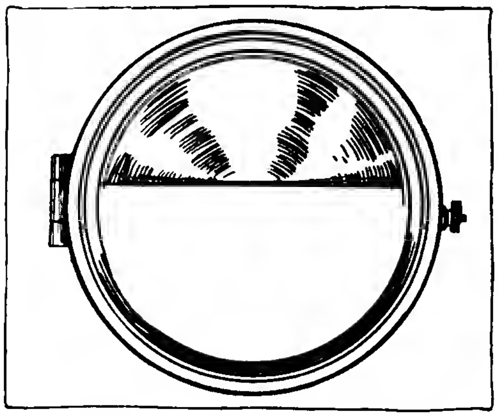
This interrupter is designed to eliminate the necessity for the vibrator on the Ford coils and at the same time to improve the ignition. It consists of a special interrupter which is wired into the ignition circuit between the magneto and the coils; the vibrators are short-circuited and so rendered inoperative. The interrupter is driven by a vertical shaft mounted in a special bracket which is attached to the crankcase at the front of the motor by bolts passing through existing holes, drive being taken from the end of the camshaft, which ordinarily drives the Ford timer; the latter is removed from its normal place and is attached at the top of the Paramount interrupter and is driven by the same vertical shaft. Advance and retard of ignition are not interfered with in any way. The shaft runs at camshaft speed. The interrupter cam has thirty-two teeth. The interrupter and the timer, working together, are so arranged that the current is always interrupted at the proper instant. No additional current is required, the regular Ford flywheel magneto current being used.—Detroit Engineering Products Co., Detroit.



Paramount Interrupter in place. Left, cam and contact arms

H-M Ray Controller

The H-M ray controller is of glass with the upper part frosted inside to a point a little below the center; the light of the upper part of the lamp is diffused, but the lower part of the beam is thrown out undimmed. The side rays illuminate the roadsides just as without the device attached. The glasses are installed in the same way as the original headlight glasses, it being only necessary to take out the old glasses and insert the new ones. Price, per pair, 7 to 9½-in. flat glasses, $1.25; 9⅝ to 11⅝ flat, $1.50.—H-M Mfg. Co., Providence, R. I.



H-M ray controller for headlights

Pamco Products

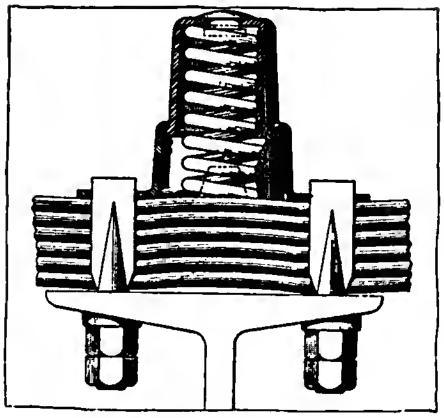
The Pamco Tire Saver jack comes in three models. No. 1 and No. 2 are toggle and lever operated and are non-adjustable. No. 1 is for Fords, and No. 2 for larger cars. No. 3 is also toggle operated, but it has a dog and rack for giving different adjustments. This jack can be operated in less than 6-in. clearance, having an offset head. No. 1 lists at $4; No. 2, $5, and No. 3, $5.

The Pamco spring bumper is a coil spring in a telescopic case and is used to

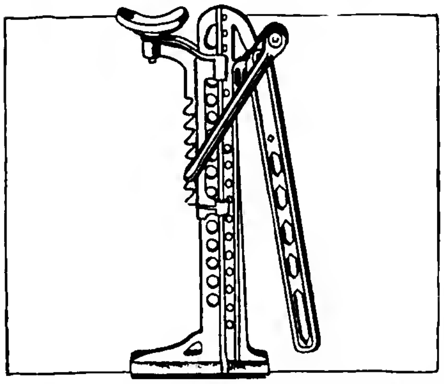
Kim torsion springs in position

replace rubber bumpers between springs and frame. The bumpers are attached by loosening the spring clips and then putting the bumper flanges underneath. They are made in two sizes, for case under and over 2500 lb. Price, per pair, $1.

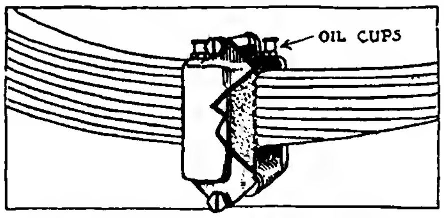
Pamco oil boxes clip to the sides of the springs and contain felt pads from which oil is fed between the leaves. The motion of the springs produces a pumping action on oil wells at the bottom, keeping the pads saturated. The boxes sell for 75 cents each. Ford size, $3 per set of four.—Auto Devices Co., St. Louis, Mo.



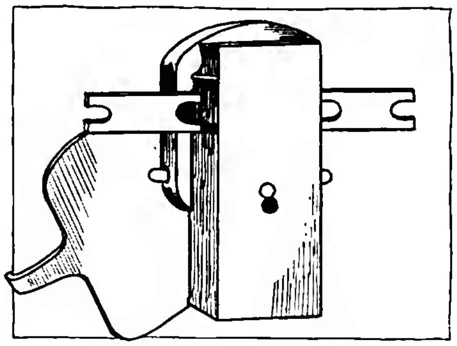
Pamco auxiliary spring bumper



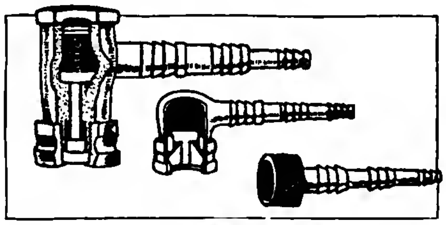
One of the three Pameo tire-saver jacks



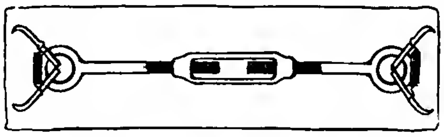
Pamco spring lubricator mounted



Sure-Cure steam vulcanizer



Two Romort air valves and a coupling



Grier closing tool for non-skid chains

Kim Torsion Springs

In the Kim device a pair of torsion springs connected by a yoke is placed between the ends of the leaf springs, or between the leaf spring and its support in the case of a semi-elliptic. There are no wearing parts. The springs can be attached to any car in a few minutes, without drilling or machine work. Price, rear set, $15; Ford set of four, $25. —Kim Mfg. Co., Inc., Merrimac, Mass.

Romort Air Valves

Romort valves are for use on tire-inflating hose and are automatic, shutting off the air when the hose is removed from the tire valve. Style A is a heavy valve for severe service and is made from a solid bronze casting. Style B also is made of bronze, but is a smaller and lighter valve and designed for ordinary service. Both valves are equipped with universal step-up stem, so that any size hose will fit, from ¼-in. to ⅝-in. Style A sells for $3 and style B for $1.

A new specialty is the Romort tank connection, for connecting the hose at the tank. Hose is disconnected by merely unscrewing the heavy knurled nut; this also has the universal step-up stem.—Romort Mfg. Co., Seattle, Wash.

Sure-Cure Steam Vulcanizer

This little portable vulcanizer has a one-piece body which is filled with water at the factory and does not require refilling, as steam is not allowed to escape and when cooled returns to liquid form. The fuel used is gasoline, which is measured into the fire-box and allowed to burn out; the makers state that the heat is automatically controlled. A complete outfit of repair material, clamp hooks, chain, etc., accompanies each vulcanizer. The finish is nickel. Price, $2.25.

Another product is the National air jack, a pneumatic jack operated by either a hand or power tire pump, a brief application sufficing to lift the largest car. To lower the car, the air is released. For storage purposes a mechanical lock is provided. The air, however, will retain its pressure for several hours, and sometimes days, at a time. The jack has a large base, being 5 in. in diameter and weighing only 7 lb. A 3-ft. hose is furnished, making attachment easy. The jack sells for $6.—National Motor Supply Co., Cleveland, Ohio.

Mecco Garages

All Mecco garages are of pressed steel, and they are made in great variety. The metal is pressed into ornamental designs or into plain shapes, and various arrangements can be had to harmonize with the surroundings; roofs may be metal shingled or tiled with Spanish type metal tiles. Covering may be built on structural steel or wood framing. Both portable and non-portable types are built; the former range in size from 10 by 12 to 20 by 20, there being fifteen sizes. Prices are from $50 up.—Moeschl-Edwards Corrugating Co., Covington, Ky.

Grier Chain Closer

The common turnbuckle is the basis of this tool for bringing together the end links of tire chains. At each end of the turnbuckle is a ring and each ring carries a pair of hooks which engage the chain links. Turning the yoke pulls up the chain. It sells for 75 cents.—P. A. Grier Co., Cleveland, Ohio.

P. & H. Robe and Poncho

This is a fleece-lined robe of lightweight waterproof material, and can be carried under the seat or on the robe rail. It can be thrown over the shoulders and fastened at the neck for use as an emergency rain-coat or weather-proof. The makers also recommend it as an engine hood cover. Price, $2.25.—Peters & Herron Dash Co., Columbus, Ohio.

Mecco sheet steel garage

Racing Advancing

SCHEDULING shorter-distance speedway races for the coming season will have a desirable effect on the speedway meets, because shorter races can only be interpreted as insuring fewer cars being eliminated due to serious breakages, which often eliminate a machine for several weeks, or, in some cases, months. Last year the long 500-mile contests proved particularly serious, due to higher average speeds than previously possible, and to the consequent strains imposed on the machines because of such. This year the machines are better able to withstand such severe tests, but added to this is the fact of shorter races, which will mean fewer cars seriously eliminated.

Still a further step that should insure better contests and more cars is the program of short events—four races rather than one long race of 500 miles. In addition to such short events conserving car stamina they will also be potential interest stimulators. Instead of one finish in a day there will be three, or perhaps four. The spectator in his own mind will get three or four times as much excitement out of the day as formerly. These short-race programs are going to be very general, and will lead back to the days of five or six years ago, when some of the best racing events were made up of short-distance contests.

The old handicap event is bound to return—that is, a handicap based on previous performances. A handicapping committee is essential. The handicap event was looked upon with more or less disfavor because of the danger connected with it. The fast cars had to go through the entire field to win. This was sometimes attended with accidents. To-day this situation has been altered, and with the circuit of board speedways it is now possible for the fast cars to do this without the danger element. There is much attraction to a good handicap race. It can crowd into a few minutes as many memories of a terrific speed duel as several hours of a 500-mile race, which lapses into a mere spectacle for a percentage of the time.

Increasing Efficiency

THE proverb "Necessity is the mother of invention" is simply another way of expressing the inertia of the human mind. We do not start to improve until some circumstance compels us to get up and hustle.

Now that there is an agitation to increase the economy of the gasoline engine, there is an immediate response, and scores of inventors are working on methods to improve our present engines or to introduce new and better types.

The possibilities of altering the present Otto cycle motor to secure more work from a given quantity of fuel are received with interest by engineers. Anything which will increase the work area in the diagrams, and which will at the same time allow the car to perform in accordance with the demands of the public, would be hailed as a valuable discovery.

Naturally the first thing to be suggested is the carrying out of the expansion line until the pressure falls almost to atmospheric, thus cutting out the high exhaust pressures which now allow about a third of the fuel energy to be ejected through the muffler. The big point to consider, however, is not whether an engine can be made to work on the extended expansion stroke method, but can it be made to do so and give the quick, snappy action demanded by the super-educated automobilist.

Let Us Conserve

THE law of progress is to eliminate waste. Many generations will not have passed before the man who makes it possible to conserve our precious mineral fuel, either by increasing the visible supply through greatly improved distillation or by the invention of an engine which can use now wasted products, will be recognized as one of those who has rendered a service of the greatest importance. His practical reward would be immediate.

Billions of barrels of kerosene for which there is practically no market to-day are being stored or lost. To find some means of using this either by converting it into a more volatile product or by finding an engine or device that will use it, would make the automobile a possibility to thousands who do not use it now, and would immeasurably increase the mileage of those cars now on the road.

S. A. E. Standards Work Progresses

Five Divisions Meet This Week —Nomenclature Committee Completes Task

DETROIT, MICH., March 29—*Special telegram*—At this morning's session of the nomenclature division of the Standards Committee, Society of Automobile Engineers, the names of all the parts of the frame, spring and steering gear assemblies were decided upon. Rapid progress is being made and the committee expects that by to-night its work will be nearly completed.

The meeting of the electrical equipment division of the standards committee was held in New York Tuesday morning, the principal work done being the revision of certain old recommendations in the data book which have lately fallen out of use. These are concerned with details of wiring and recommendations as modified are much wider. A large part of the time was spent in discussing the design of lamps and lamp bulbs, particularly from the viewpoint of glare. A sub-committee has been appointed to carry the investigations already made very much further and to confer with makers of lamps and bulbs. It is hoped that standards of a large number of the parts which go to make up a lamp will enable glare to be eliminated without the need for elaborate focusing or other devices. The subject is a large one and bristles with difficulties, but the electrical equipment division is very hopeful of ultimate success. This matter will be one of the principal subjects for discussion at a general meeting of the Standards Committee which takes place in Cleveland on April 21.

A Busy Week

Activities of the standards committee this week include meetings on Wednesday, Thursday, Friday and Saturday of the nomenclature, engine and transmission, miscellaneous and research divisions.

The activities of these divisions are in general continuations of previous work. The nomenclature division has drawn up a list of names of parts which it is getting ready to submit at an early meeting of the national organization. These names of parts are for use in standard parts price lists in which it has been found that under present conditions there are several names for the same part used by different concerns in the automobile business. This results in confusion to the stock managers and also to the general public.

The engine and transmission division is collecting data necessary to the plotting of average curves of engines of different classes. These curves will furnish what may be called expectancy charts as a check on design. Sub-committees of this division are gathering information in order to develop proposed standard designs relating to V belts and pulleys, poppet valves and hand-starting cranks.

The miscellaneous division has a large number of small details. Some of the topics for which they are discussing standard dimensions are license plates and brackets, tire pump bases, standard weight of car, location of identification number, location of engine number, hose clamps and fittings for hose diameters from 3/16 to 3 in.

The research division is taking up the matter of more elaborate forms for the gasoline consumption test and is also working out a standard method for acceleration tests. This division has another matter under consideration dealing with standard tap and drill sizes.

Midgley Is Now Lancaster Tire & Rubber Co.—Capital, $850,000

LANCASTER, OHIO, March 25—The name of the Midgley Tire & Rubber Co., this city, was changed, at a recent special meeting of the stockholders, to the Lancaster Tire & Rubber Co. At the same time the capital stock of the company was increased from $550,000 to $850,000. The $300,000 increase is 7 per cent cumulative stock. Certain stockholders have already underwritten $100,000 worth of this preferred stock, so it means the putting in of an additional $150,000, as $50,000 worth of common stock was purchased a short time ago. It is also known that as rapidly as additional funds are needed the other preferred stock will be purchased.

The new directors are: F. A. Miller, Columbus, Ohio, general manager of the H. C. Godman Shoe Co.; H. B. Peters, Lancaster, Ohio, president Fairfield National Bank; C. S. Hutchinson, Lancaster, Ohio, assistant secretary H. C. Godman Shoe Co. and vice-president Lancaster National Bank; Harry Davis, Pittsburgh, Pa., president Harry Davis Enterprises Co.; E. E. Lerch, Columbus, Ohio, secretary of the H. C. Godman Shoe Co.; H. V. Blaxter, Pittsburgh, Pa., of Lazier & Blaxter, attorneys-at-law; J. T. Rose, Lancaster, Ohio, president of The Lancaster Tire & Rubber Co.

The officers of the company are: J. T. Rose, president; C. S. Hutchinson, vice-president, and G. A. Stephenson, secretary and treasurer. Walter H. Hermann is factory manager and T. B. Davies is manager of sales.

VANCOUVER, B. C., March 25—Up to November, 1915, there were 9100 automobiles registered in British Columbia, as compared with 6387 in 1914.

Briscoe Disposes of Argo Plant

Former Disco Manager Secures Control of Jackson Plant—To Continue Cars

DETROIT, MICH., March 28—Announcement was made to-day by the Briscoe Motor Corp., Jackson, Mich., that a contract has been made with Mansell Hackett, former manager of the Disco Starter Co., this city, for the sale of the Briscoe interest in the Argo Motor Co., Jackson, Mich.

To Widen Scope

Mr. Hackett will take immediate charge of the Argo Motor Co., to which he will bring an entirely new organization, and it is anticipated that he will extend its business activities in a large measure within a very short time. Mr. Hackett is well known in automobile circles and has made an enviable position for himself by putting on its feet the Disco Starter Co., which he purchased from a receiver.

The Briscoe Motor Corp. will hereafter devote its entire time, organization and the new plants which it recently acquired and has under construction to the manufacture and sale of Briscoe motor cars exclusively.

Mr. Hackett states that it is the intention to continue the present Argo models for the time being, adding a light delivery car on the same chassis. However, larger cars to sell between $600 and $700 will be brought out later, the plans being for a production of 5000 the first year.

Stover Tractor Makes Appearance

FREEPORT, ILL., March 27—The first model of the new Stover tractor was turned out this week by the Stover Engine Works, which is to manufacture the machines. The wheelbase is 90 in.; the front wheels are 36 in. in diameter and the rear drive wheels 56 in. The latter are equipped with cross cleats. When used in sod or stubble plowing, extra spurs are furnished, twenty-four to each wheel, which contributes to the footing of each wheel. The motor has four cylinders, and is rated at 40 hp. The tractor is to be sold for a three-plow machine, but has a maximum capacity of four. A 20-in. steering wheel enables the operator to handle the machine as easily as an automobile. A Bennett carbureter and air cleaner is part of the equipment. The Stover company plans to turn out 100 or more of these machines during the coming season, and work will commence as soon as the tests of the first model have been completed.

To Compile Industrial Data

Federal Trade Commission Plans Closer Co-operation with All Manufacturers

Boston, Mass., March 28—In an address before the Boston Commercial Club here last night Edward N. Hurley, vice-president of the Federal Trade Commission, gave a summary of the industrial research done by the commission during the year in which it has existed and outlined the plan for securing better co-operation between the commission and manufacturers in all industries in the United States. This plan comprises the compilation of data on production, sales, investment, depreciation, etc., so that each member of an industry, when furnished with the resulting summary, will have a clear conception of the general condition of the industry and what remedies may be applied to existing difficulties. Brief extracts from Mr. Hurley's address follow:

"The Federal Trade Commission has been in existence one year, and after surveying the field, we found from a preliminary investigation that 200,000 corporations out of a total of 260,000 engaged in the manufacturing and mercantile business of the United States were eking out an existence; 100,000 of them did not earn a penny. Out of 60,000 successful corporations doing a business of $100,000 a year over 30,000 charged off no depreciation whatever. Only 10 per cent of our manufacturers and merchants know the actual cost to manufacture and sell their products; 40 per cent estimate what their costs are, and 50 per cent have no method but price their goods arbitrarily. Most of the manufacturers and merchants who do not know what their goods cost are basing their selling price on what their competitors sell for and with only this knowledge for a basis they are frequently cutting prices and demoralizing the industry in which they are engaged.

"There were over 22,000 business failures in the United States last year; more than 20,000 of them were small concerns. We all know that a large percentage of business is run at loose ends, haphazard and without the proprietors really knowing at any time how they stand or whether they are making a profit or a loss.

"In order to co-operate intelligently with the manufacturers and merchants of the country the Federal Trade Commission must have these facts. With this thought in mind we recently mailed to every corporation in the United States a form containing a few simple questions pertaining to their industries. This information embraces the products which they manufacture, their annual sales, the capital invested, and other principal items, such as depreciation, etc. These data will be compiled by industries and a summary of results sent to each company engaged in that particular line. This will give each man in the business an opportunity to know whether or not the industry he is engaged in is in a healthy condition."

Stearns-Knight Advances Car Prices $50 March 20

Cleveland, Ohio, March 23—The F. B. Stearns Co., this city, announces an increase in price of $50 per car on all models, beginning March 20. The Apperson Bros. Automobile Co. has announced that there will not be any increase in list prices on current models. The prices placed on the 1916 models will remain unchanged until the 1917 models are announced.

The following list gives the price increases and decreases made during 1916:

INCREASE

Company	New Price	Old Price
Chalmers	$1,450	$1,350
Dort	665	650
Studebaker—		
Roadster Four	850	825
Seven-Passenger Four	875	845
Landau Roadster Four	1,150	1,145
Three-Passenger Six	1,060	1,025
Seven-Passenger Six	1,085	1,050
Saxon Six	815	785
Marmon—		
Five-Passenger	2,900	2,700
Seven-Passenger	2,950	2,750
Three & Four Passenger	2,950	2,750
Buick Six—		
Roadster	985	950
Touring	1,020	985
Empire Four	935	895
Scripps-Booth Four—		
Roadster	825	775

DECREASE

Company	New Price	Old Price
Maxwell of Canada—		
Touring Car	$850	$925
Roadster	830	900
Cole	1,595	1,785
Overland	695	750

Napoleon Car on Market

Napoleon, Ohio, March 24—Beginning April 1, a light four-cylinder 25-hp. chassis will be produced by the Napoleon Auto Mfg. Co., this city. A plant has been secured and all the necessary machinery and tools and equipment have been placed and are ready for operation.

The company will capitalize for $50,000 to $75,000.

The following are a few of the features of the car: selective transmission; disk clutch; double system, starting and lighting; I-beam front axle; semi-floating axle, rear; irreversible steering gear; demountable rims; vacuum gasoline feed; gasoline tank in rear; cellular type radiator; semi-elliptic front springs, and cantilever rear springs.

The officers of the company are: President, A. O. George; vice-president, F. P. Diemer; vice-president, G. M. Donnelly, and general manager, F. M. McGrew.

Sunbeam Racers for America

Two 300-In. Sixes Built—Christiaens to Drive One—Two New Fiats

Paris, March 11—Around Brooklands track it is an open secret that the Sunbeam company has built a couple of six-cylinder 300-cu.-in. racing cars specially designed for American track conditions. The military authorities of England have given permission for one of these cars to be exported, and arrangements are well in hand for Joseph Christiaens to handle it in some of the leading American races. The new Sunbeam is a four-valve motor in which has been incorporated all the experience gained during recent months in the building of aviation engines. In trial work the car has shown a speed of 120 m.p.h. The acceleration is remarkably rapid, it being possible to get the motor to its most efficient speed of 3000 r.p.m. on one of the straightaways of Brooklands, standing start. Joseph Christiaens, who has been selected as driver of this car, is the Belgian who drove the six-cylinder Excelsior into sixth place at Indianapolis two years ago.

Two Fiat Racers

Fiat is showing interest in racing, and although no decision has yet been arrived at regarding an American campaign, two cars are in preparation at the Turin factory. These are the 1914 Grand Prix models with engines redesigned with four valves, and increased in bore so as to bring the cubical capacity to the maximum of 300 in. The engines have undergone thorough bench tests and are declared to be very satisfactory. Drivers selected for these cars are Jack Scales and Antonio Fagnano. Scales is an Englishman on the testing staff of the Fiat company at Turin, and was driver of one of these cars in the last French Grand Prix at Lyons. Fagnano is one of the old school of drivers who acted as mechanician to Felice Nazzaro during the period when the Italian crack got away with all the leading prizes in Europe.

Ort Goes to Willys-Overland

Detroit, Mich., March 27—John A. Ort, export manager of the Hudson Motor Car Co., resigned recently to join the Willys-Overland organization. Mr. Ort was formerly connected with the National Cash Register Co., Dayton, Ohio, and with the Burroughs Adding Machine Co., Detroit. He was also the chairman of the Detroit Board of Commerce export committee.

Peace No Remedy for High Prices

Purchasers Do Not Expect War's Close Will Relieve Materials Market

DETROIT, MICH., March 27.—There is no longer any tendency for the purchasing departments of car and parts manufacturing concerns to discount the present materials market conditions. Several weeks ago there were a few who held the view that conditions would improve as the spring advanced, but evidently their method of figuring was wrong, for each week sees increasingly high prices for everything that goes into a car.

Nor is there any hope that with the cessation of hostilities abroad there would be any betterment of price. On the contrary, all now believe that with a great foreign demand opening up when industries of Europe again take up peaceful pursuits, the exportation of iron and steel and other materials will be enormous for the next two or three years, at least, and that any hopes for lessening of prices on the declaration of peace is indeed a forlorn affair.

Some telling arguments are advanced by F. E. Watts, chief engineer of the Hupp Motor Car Co., who believes with most others that we are in for high prices for some time to come. He says in part:

"At the present time the steel companies are contracting for the third and fourth quarters of this year at the present market prices, which are high. In order to protect themselves on the raw material, the steel companies are now contracting for their pig iron, coke, steel scrap and alloying elements, the prices of which are extremely high. Practically all of the ferro-manganese used in the manufacture of steel is imported from England. The latest quotation made on this product was $225 per ton, in comparison with $40 per ton before the war started. The last week the British government declared an embargo on the exportation of ferro-manganese, and it will have to be obtained from some source, as yet undeveloped.

Railroads Buy Heavily

"The railroad companies are ordering very heavily to keep their rolling stock and rails in condition. In the first two months of this year 641 locomotives were ordered, approximately 10,000 freight cars of various types, and the rail tonnage will be over 150,000 tons.

"The Russian government, last week contracted for 60,000 tons of rails. The locomotives will have the tendency to keep the price of tubing up, as there is approximately 10,000 ft. of this material used in every locomotive.

"The shipbuilding companies are busier than at any previous time, and the contracts held by the American shipyards will keep them busy throughout 1916, part of 1917, and some boats are being contracted for with delivery specified in 1918. The engines in these boats will also require an immense amount of tubing, and the decks and plates for the hulls will require a large tonnage of cheap steel.

"At the present time there is very little steel being produced in Europe, and with the destruction of railroads and railroad equipment, and bridges, there is going to be an immense demand for steel after peace is declared. Steel men estimate that the exportation of steel will be very large for at least two or three years after the war is over.

"We cannot possibly escape the effects of this general increase. What we gain in one place by purchasing, manufacturing, or designing skill, or by getting parts from companies which have raw materials in stock, we lose elsewhere."

Ford Excluded from California Interstate Business

SACRAMENTO, CAL., March 28—Failure to pay the State franchise tax of last year has caused a proclamation to be issued by Governor H. W. Johnson, excluding from interstate business in California about 5500 corporations, including the Ford Motor Co. In the case of the Ford company, the tax amounted to $24,000, which the company refused to pay on the ground that it was excessive. A penalty of $100 a day is fixed for violation of the proclamation which declares the franchise forfeited. The company, however, can pay up and revive itself at an expense of $51,000 besides the tax. It was stated that the courts would probably be asked to enjoin the enforcement of the Governor's proclamation.

Belmont Electric Announced

WYANDOTTE, MICH., March 28—The Belmont Electric Auto Co. will shortly start the production of an electric delivery car selling at $985, a four-passenger car at $1,400, and a six-passenger limousine for $1,600. The concern will occupy the Murphy Machine Shop on Biddle Avenue, this city. The company plans to produce 250 cars the first year.

The car, it is stated, is capable of 75 miles on one charge of the battery. The company is also planning to provide a charging plant, patents applied for, for $150, which will make the electric car owner entirely independent of charging stations. J. H. Bishop of Wyandotte is president of the company. Temporary offices are at 410 Scherer Building, Detroit, Mich.

Car Production Breaks Records

Ford Sure to Build 500,000—Other Concerns Surpass Previous Outputs

DETROIT, MICH., March 28—Although prices of materials continue to advance and factory officials see no hope of relief in the near future, production of cars continues to make record-breaking strides here and in the surrounding automobile manufacturing centers. With the freight car situation also adding to the troubles of the factories, it is surprising that shipments continue to increase as the days go by. Many prominent manufacturers have increased the prices on their cars to take care of the added cost of materials, but all reports seem to indicate that even the increased amounts which the customers have to pay for their cars are not in any way affecting the enormous demand, which continues to be much greater than the most optimistic would have cared to predict some months ago.

Information received from the Ford company indicates that there is no longer any doubt of 500,000 Fords being built for the present fiscal year. Plans have already been laid for 1,000,000 Fords for 1917.

So far as the 1916 outputs are concerned, it may be said that not one of the factories now has any doubt of its ability to market as many, or even more cars than were called for in the original monthly production schedules.

As an instance of present manufacturing conditions, Studebaker reports that the daily production will soon be raised from 300 to 400 cars. Reo is turning out about 125 cars per day, Chevrolet is increasing its production as predicted some months ago, so as to be producing over 300 cars per day next month, with the ultimate idea of turning out 460 per day in August. Cadillac will ship more eights this year than ever before and Dodge's production is now running about 300 per day. Maxwell will soon have its second assembly conveyer system in operation, which will allow of a possible production of about 500 cars per day. At its present pace Saxon will easily turn out the 30,000 cars which are planned for the present year. Similar stories emanate from practically every factory in the big production area.

Tracy Is Premier Purchasing Agent

DETROIT, MICH., March 29—P. W. Tracy, purchasing agent of the Paige Motor Car Co., has signed to go with the Premier Motor Corp., Indianapolis, Ind., in a similar capacity.

To Show Cars in Paris

Automobiles and Trucks Will Play Important Part in Reconstruction

PARIS, March 27—Motor vehicles will play an important part in the great work of reconstruction which must follow the declaration of peace in Europe. Preparations for undertaking this tremendous task are already well under way and include expositions such as the Reconstruction Exposition, to be held during the latter part of May and through June and July, and the fair and market now being held in Agricultural Hall, London.

The Reconstruction Exposition, which will be held on the terraces of the Tuileries Gardens and the Halls of the "Jeu de Paume," will be very broad in scope and will be open to exhibits of automobiles, motor trucks, parts, accessories, etc., in fact anything which is admitted to an automobile show in the United States. The exposition is semi-official in character and all goods destined for the display have preference over all others on the French lines to Bordeaux and on the railroad to Paris. Fifteen days notice to the general agent in New York is necessary, however, to secure this preference. The same applies to New Orleans, where the same preference is given. The secretary of the exposition suggests that it would be advantageous for automobile concerns desirous of sending exhibits to co-operate with the chambers of commerce in their respective cities and group their shipments in order to have them arrive at New York or New Orleans at about the same time.

Big Sales Expected

The secretary also declares that those exhibiting will do a larger business than at most of the American shows, for not France alone but many other European countries, such as Spain, Portugal, Egypt, Italy, Greece, etc., will be represented by people anxious to buy cars and to secure agencies. He points out that reconstruction in Europe will bring American manufacturers many times more business than the war orders, but that buyers here will not purchase unless they can see a sample. Hence the reason for the exposition.

The demand for American automobiles selling under $1,000 is entirely beyond the belief of Americans. They are wanted all over Europe by the thousands. Many people are endeavoring to secure parts to assemble them here to meet the demand for cheap cars.

Farm Possibilities

Europeans do not realize the wide use American farmers make of their cars as farm implements, for sawing wood, pumping water, using them as tractors, etc., and if they could be shown some of these possibilities the market would be correspondingly widened. Farm tractors will be in immense demand in Europe after the war, and American manufacturers will have enormous opportunities in introducing their machines if they make the direct effort necessary to bring them before the European farmers.

40-Cent Gasoline Not Expected

NEW YORK CITY, March 27—The price of gasoline in the East remains unchanged. All four of the principal companies—Standard Oil, Crew-Levick, Gulf Refining and Texas—are quoting 24 cents to garages in New York and 23 cents in New Jersey. Prices in Connecticut are at the same level as for New York. Of the Western cities Minneapolis alone has a higher price, Independents advancing low grade gasoline, tank wagon basis, to 20½ cents, medium 24½ cents and high 26 cents. The Standard Oil prices in Minneapolis are one cent lower for the lower and medium grades.

In view of the fact that the higher prices now prevailing have served to stimulate production, conservative oil men are beginning to question the probability of further increase. It is generally conceeded that the present supply and demand situation justifies current prices. Oil men, therefore, are inclined to look askance at predictions of 40-cent fuel.

The following table gives prices of fuel at present obtaining and those for August, 1915. Prices for March, 1915, were at their lowest, which was 2 to 3 cents below the August price.

	Current Price, Cents	August Price, Cents	Advance, Cents
Boston, Mass.	25.0	15.0	10.0
Buffalo, N. Y.	23.0	12.0	11.0
Chicago, Ill.	18.5	10.5	8.0
Cincinnati, O.	23.0	12.0	11.0
Denver, Col.	22.0	12.0	10.0
Detroit, Mich.	19.0	11.0	8.0
Hartford, Conn.	24.0	14.0	10.0
Houston, Tex.	20.0	12.0	8.0
Kansas City, Mo.	16.8	9.8	7.0
Louisville, Ky.	21.0	12.0	9.0
Minneapolis, Minn.	19.5	11.5	8.0
New York City	24.0	14.0	10.0
Newark, N. J.	22.0	11.0	11.0
Philadelphia, Pa	25.0	13.0	12.0
Pittsburgh, Pa.	25.0	14.0	11.0
Portland, Me.	25.0	16.0	10.0
Raleigh, N. C.	24.0	15.0	9.0
St. Louis, Mo.	17.9	10.9	7.0
San Francisco, Cal	18.0	11.5	6.5
Seattle, Wash.	18.5	12.0	6.5

Wallman Co. Is Now Inglis

MILWAUKEE, WIS., March 27—The Wallman Mfg. Co., maker of gasoline and oil storage systems, tanks and pumps, has been succeeded by the Inglis Mfg. Co., newly organized, of which C. W. Inglis, of the Milwaukee Steel Foundry Co., is president and treasurer. Charles Inglis, for twenty-eight years past with the International Harvester Co.'s Milwaukee branch, is secretary and manager. It is the intention of the new concern to improve and increase the production of garage systems.

Another Gasoline Resolution

Massachusetts Congressman Calls on Attorney General To Cite Prosecutions

WASHINGTON, D. C., March 27—Another legislative attempt to find out why the price of gasoline is now so high has just been made by Congressman Treadway of Massachusetts, who has introduced a resolution in the House calling on the attorney general to furnish data to Congress showing what prosecutions have been inaugurated.

The resolution provides, in effect, that the attorney general transmit to the House of Representatives full information relative to prosecutions, if any, that have been inaugurated by the Department of Justice against any person, firm or corporation for violation of the Sherman anti-trust act and amendments thereto in relation to the production, transportation and sale of gasoline, and especially with relation to the increase in price in certain localities of the United States and the variation in price between certain sections of the United States. It is further provided that in case the attorney general has not instituted prosecutions on this subject he is directed to transmit to the House his reasons for failure to bring such prosecution.

House Names Sub-committee to Decide on Relief Plan

WASHINGTON, D. C., March 28—The various resolutions proposing an inquiry into the rising price of gasoline were placed in the hands of a sub-committee to-day by the House Committee on Mines and Mining. Representatives James of Michigan, Van Dyke of Minnesota and Garland of Pennsylvania were appointed to decide what course should be pursued.

There are two resolutions before the sub-committee. One, by Representative Randall of California, proposes that the Federal Government take over the oil output of the country and operate wells and refineries. Another, offered by Representative Carter of California, calls for an investigation by the Bureau of Mines.

The sub-committee will examine documentary evidence and also consider a report soon to be made by the Federal Trade Commission on the subject.

Wondertone Opens Chicago Office

NEW YORK CITY, March 28—The Motor Appurtenances Corp. of this city has opened a branch in Chicago at 1469 South Michigan Avenue. The company manufactures the Wondertone horn and other motor car equipment.

N. G. E. A. Adopts Standards

Approves Magneto and Carbureter Flange Standards —Tractor Suggestions

CHICAGO, ILL., March 25—The Society of Automobile Engineers standard magneto practice was adopted by the National Gas Engine Assn. Standards Committee at a meeting held at the Sherman Hotel here to-day. Another S. A. E. standard to be adopted was that for carbureter flanges. The ⅞-in. eighteen-thread spark plug was recommended for adoption.

A large number of tractor men attended the meeting and a section of the Standards Committee was formed to take up this work. This section will consider the subject of wheel sections, plow hitches, engine mountings, etc. They will hold several meetings between now and the time of the annual convention in Chicago June 27, 28 and 29, at which time they will report.

Among the points discussed for standardization were magneto mounting dimensions and couplings, spark plugs, screw threads, cap and die limits, carbureter fittings, fan belt speed, clutch pulley spiders and horsepower rating. The only special tractor feature taken up was that of draw bars for wagons and other trailers.

More Study Required

As this was the first regular meeting of the Tractor Section no definite recommendations were made of standards in most instances, as it was felt that in the majority of cases further study was required before a recommendation could be made.

Export Trade Problems

The export trade in tractor engines which is anticipated necessitated the consideration of whether or not the spark plug adopted should be of metric thread instead of U. S. standard, and a very lively discussion arose on this score. One suggestion was that arrangements be made by which spark plugs of any pitch thread and of any diameter from any predetermined maximum could be used. This, it was suggested, could be accomplished by making the spark plug hole considerably larger than the ⅞-in., and put in a bushing which in America could take a ⅞ or ½-in. U. S. standard thread plug, and for foreign use it will be necessary only to change the bushing for one which would take a metric plug. The discussion of this subject brought up a number of interesting points. George A. Schwer, of the Dauch Mfg. Co., insisted that a bushing of liberal diameter be used, as the original suggestion of a shell which replaced the ⅞-in. plug, and that the ½-in. plug would not be safe, as it would not stand up. Chairman Charles Kratch of the Sumpter Electric Co. suggested that all holes be tapped for bushings so that any plugs to answer the foreign or domestic be used. S. M. Walker, head of the gas engine department of Montgomery Ward & Co., suggested that inasmuch as the trade would be called upon to supply large quantities of engines for foreign shipment, the trade should be prepared to meet this demand as well, and that the bushing should have a metric thread, which he believed was the U. S. Government as well as the foreign standard. Mr. Walker felt that it was the best policy in catering to the foreign trade, as well as the domestic, not to try to make the market buy what manufacturers were selling so much as it is to sell them what they want to buy.

Putting in Bushings

Fred Glover of the Emerson-Brantingham Co., Rockford, Ill., voiced an opinion which was generally diffused that the method of putting in a bushing in every engine made in order to take care of the comparatively small proportion of the output for foreign trade would be uneconomical. Further, that the use of a bushing would put the plugs too far away from the water space. H. T. Buffington, of the Minneapolis Steel Machinery Co., concurred in this, and stated that where metric threads were needed it would not be difficult to tap out the holes for them. The bushing idea finally was dropped, and the S. A. E. standard plug recommended.

For standard magneto dimensions the S. A. E. standards were recommended for adoption. However, it was felt that there was one feature in tractor practice which was not cared for by the S. A. E. standards, and this was the case of impulse starting, which has been developed for use in tractor engines. There are four or five magneto concerns offering these impulse starters and all of them differ from ⅛ to ¾ in. in the dimension from the first holes in the base to the face of the coupling, and it also was brought out that the length of magneto shaft end to the first holes in the base varied among the magneto makers.

Magneto Couplings Discussed

This brought up the point of magneto couplings, which was discussed by Mr. Williams, who developed the conditions necessary for flexible couplings for tractor magneto drive, and illustrated his points with samples of a number of different types. The question of the standardization of couplings was referred back to a sub-committee for a later report.

The standards of the Society of Automobile Engineers were used as a basis to a great extent in the discussion of the standards for tractors, and this section of the standards committee of the N. G. E. A. realized the value of working in harmony with the S. A. E. By special request the standards committee of the Society of Automobile Engineers was represented by Mr. Herman, of the Chicago Screw Co. There were in all twenty-five representatives of the tractor and allied interests present, and it is to be expected that the next meeting of this section will see even closer co-operation with the S. A. E.

To Build Lane Worm-Driven Light Truck In Kalamazoo

KALAMAZOO, MICH., March 25—The Lane Motor Truck Co. of Kalamazoo, Mich., has been recently organized with a cash capital of $25,000, M. H. Lane being president and general manager, and G. E. Bardeen, secretary and treasurer. The directors are M. H. Lane, G. E. Bardeen and F. G. Gilsky. The company will build a factory at once and expects to begin manufacturing about May 1.

The company will bring out a light worm-driven truck with a wheelbase of 120 in. and pneumatic, solid and cushion tires. The unit power plant will be 3¼ by 5 in., with a three-speed transmission and multiple-disk clutch. The radiator will be a fin and tube type. Semi-elliptic springs 2½ in. front and rear will be used with Hotchkiss drive. Both service and emergency brakes will be internal expanding on the rear wheels. Front axle will be an I-beam with roller bearing, rear axle Sheldon worm drive with a gear ratio of 6.2 to 1. Wheels will be artillery types with square spokes. Tires will be 34 by 4 pneumatic front and rear. There will be four body styles.

Suggests Headlight Ordinance

ST. PAUL, MINN., March 25—Secretary T. M. Johnson of the automobile club has drawn an ordinance for approval by the club and city council covering dimming of headlights of automobiles. The present ordinance leaves it to the discretion of each policeman to decide whether the particular lights are too bright. The proposed law requires a lamp shedding a ray of light 75 ft. to be adjusted so the beam will not be higher than 3 ft. above the ground.

Turney Radiator a M. A. M. Member

NEW YORK CITY, March 25—At a meeting of the executive committee of the Motor and Accessory Manufacturers held in the association's offices, New York City, recently the following concern was admitted to membership:

Turney Radiator Co., manufacturer of radiators for passenger cars, trucks, tractors, and aeroplanes, Canal Street, Rome, N. Y.

Car Shortage Still Serious

Situation Is Practically Unchanged—Railroads Are Doing Their Best

DETROIT, MICH., March 28—The freight car shortage situation remains practically unchanged. It has not become worse during the past week. Traffic managers of automobile manufacturing concerns agree that the railroads are doing all they can do to remedy the situation, but there is no question that with the congestion in the East persisting, with the bad weather continuing, little headway is possible.

There are also a number of things which happen, and which according to railroad men show that manufacturers are also to be educated along lines about which little is said. A railroad freight manager said that he had received a report from the freight agent in one of the cities along his road, advising him that a certain dealer in that city will not take delivery of two carloads of automobiles now there until April 5. The reason given is that these cars were ordered shipped to arrive on a certain day, but not before April 5. The manufacturer thought it just as well to ship a week earlier, but the dealer has made his financial arrangements to take delivery of the shipment April 5, and not March 25. Consequently in this case the dealer is not to blame, it is all the fault of the manufacturer if the cars are not taken out promptly. This happens quite frequently among manufacturers of automobiles, said the railroad man, more so than among any other manufacturers.

Railroads Losing Thousands

Another railroad man said that the railroads are losing thousands of dollars because of the freight car shortage and that they are doing their utmost to have as few idle cars as possible. However many roads keep cars from other roads on their tracks too long instead of reshipping them promptly from where they came from. Thus, it is claimed that there are a large number of Coast cars in the Detroit territory which should have been on the way to the Coast a long time ago.

At Dodge Bros. plant it was stated that no matter what is being done, not enough railroad cars can be had. The concern lacks 35 to 40 per cent, and this means all kinds of freight cars fit to be used for shipping automobiles. As far as regular automobile equipment is concerned the roads furnish only one-fifth or one-sixth of what Dodge needs. However it is felt that the railroads are doing what they can.

Fully 50 per cent of all outgoing carloads from Detroit contain automobiles or automobile parts, according to the manager of the freight division of one railroad. Whether the freight cars contain complete cars or only parts, makes no difference in the billing, and thus this road cannot tell, it is claimed, how many carloads of automobiles and how many carloads of parts, it is handling. This information could only be obtained from the shipper.

Standard Truck Plant Plans

DETROIT, MICH., March 25—The plans for the new three-story plant of the Standard Motor Truck Co., show that the structure will be 130 by 160 ft., between Lafayette and St. Paul Avenues, adjoining the Michigan Central belt line. The ground floor will be occupied by the assembling, blacksmith, shipping and receiving departments besides a day and night service department. The front part of the second floor will be occupied by the general offices and its sub-offices, while the rear part will have the machine shop, stock room and the woodworking department. On the third floor, the fore part will be used as display rooms and the rear portions will be occupied by the painting, varnishing and trimming departments.

It is estimated that the cost of this building will be in the vicinity of $100,000, and the new machinery which will be installed after the building is completed will cost approximately $100,000.

10 per Cent Increase in Pierce-Arrow Wages

BUFFALO, N. Y., March 23—An increase of 10 per cent in wages for its employees has been made by the Pierce-Arrow Motor Car Co., this city. The increase dates back to March 3 and includes daily, weekly, monthly and piece-work rates in all departments.

Walz Resigns from Johns-Manville

NEW YORK CITY, March 28—C. H. Walz has resigned his position as manager of H. W. Johns-Manville Co.'s local automobile accessory department to take effect March 31. He will return to Philadelphia to engage in the automobile accessory specialty line. He has taken quarters at 1335 Mount Vernon Street, where he will handle the Genemotor system for Ford cars.

Overland Will Employ 18,000

TOLEDO, OHIO, March 27—As soon as the office building in this city of the Willys-Overland Co. is completed, the office force will be increased to 2000, making the total number of employees 18,000.

Test Cotton Tire Fabric

Bureau of Standards Aims To Aid Mill Operators in Uniform Testing

WASHINGTON, D. C., March 27.—The Bureau of Standards, Department of Commerce, has just completed a paper entitled "Standardization of Automobile Tire Fabric Testing." The paper is the result of a study of the causes of variation and confusion in the interpretation of results of commercial tests on tire fabrics by various mills. The work was carried out particularly with a view toward getting some standard method as regards test piece and machine for testing 17¼-oz. cotton tire fabric.

The chief causes of variation in test results were found to be due to different varieties of testing machines, sizes of test specimens, difference in quantity of moisture of the fabric at time of test and in methods of selecting samples and differences in the fabric.

Machines Differ Widely

The difference in strength of the same fabric found between results obtained upon two testing machines was often large. In one case the difference was 40 lb. on tensile tests where the strength of the fabric was about 225 lb. Variations caused by different sorts of test pieces led to the belief that a test specimen 1 in. wide and 3 in. long is as satisfactory as any other. The reason for the difference in results from two testing machines, the bureau states, is probably due to two causes; first lack of calibration of the instruments and second, some inherent defect in the mechanism. It is strongly recommended, therefore, that testing machines be calibrated at frequent and regular intervals. In general, tests on bone dry samples give more uniform results and for this reason this method has been tentatively accepted for tire fabric testing.

The report touches on the hygroscopic quality of cotton fiber. It states that automobile tire fabrics are generally sold in rolls of from 100 to 500 yd. each and in some instances moisture is added to the cloth when it is rolled for shipment. Cotton tire fabric under such conditions may contain from 3.5 to 10.5 per cent of moisture, or 100 parts of dry material. Preliminary tests show that for each 1 per cent increase moisture upon the basis of 100 parts dry material there is an increase in tensile strength of approximately 7 per cent.

Knapp Completes Plant Additions

DETROIT, MICH., March 27—The A. C. Knapp Co., which makes tops and does a general car trimming, finishing and painting business, recently completed additions to its plant which give it a total of 100,000 sq. ft. of floorspace, not including the factory buildings of the former Benham Mfg. Co., and of the former Eby Auto Parts Co. Production will be doubled and it is probable that several novelties in the top line will be brought out soon. The company has a large number of orders on the books and expects this to be its banner year. A. F. Smith has been made general superintendent of the top department. He was formerly superintendent of the body department of the Studebaker Corp.

Hoover Ball Doubles Plant

ANN ARBOR, MICH., March 27—The Hoover Steel Ball Co. will double its plant this year, adding 42,000 ft. of floor. The entire new addition will be in operation by Oct. 1.

The company will increase its issued capital stock from $300,000 to $450,000, leaving $100,000 still unissued. Stockholders have been notified that 15,000 shares of a par value of $10 each will be offered for sale and that each stockholder will be permitted to purchase up to 50 per cent of his present holdings. The stock is said to have been selling at $125 and it stated that $75 a share has been offered for the rights.

R. C. H. Corp. to Furnish Parts

DETROIT, MICH., March 25—Having temporarily discontinued the manufacturing of automobiles, the R. C. H. Corp. will devote its attention to the continuation of the repair parts business for R. C. H. cars. Quarters have been secured at 31-33 Woodbridge Street, East Detroit, Mich., and the entire stock of parts, jigs, tools, dyes, patterns, etc., has been moved to this location.

The personnel and management of the company remain the same, Charles P. Sieder being president and general manager and Ted F. Drews assistant general manager.

Work Starts on Buick Foundry

FLINT, MICH., March 25—Work on the new foundry plant of the Buick Motor Co., is progressing, but not as fast as desirable. This is due partly to the lack of laborers, carpenters and other workers. The structural work has been started.

Alloy Steel Plant in Hartford

HARTFORD, CONN., March 25—Peter A. Frasse & Co., Inc., will shortly erect a factory in Hartford, having purchased a site 320 ft. facing on the Boulevard. The building will be a saw-tooth type 320 by 100 ft. It will be used for rolling and heat treating high grade alloy steels.

Bad Truck Bill in Maryland

Would Tax Commercial Vehicles on Ton-Mile Basis and Restrict Load

BALTIMORE, MD., March 24—Perhaps the most drastic and unreasonable motor truck taxation bill ever read has just been introduced into the Maryland Legislature by Senator Bennett of Wicomico County. The bill would tax motor trucks which are operated over State or State-aid roads for the carrying of freight on regularly-constituted time schedules, in Maryland according to the ton-mileage they make and also by the mile and would restrict the load per inch width of tire to 500 lb.

A $4,000 Yearly Tax

The real meaning of the proposed legislation is apparent when by computation it is ascertained that a 5-ton truck making 50 miles a day and delivering 25 tons would be charged $4,124.99½ per year for the privilege of operating over the roads for which privilege the truck owner already pays in his general taxes.

The moneys so raised are to be applied to the roads, according to the plan of the genius from Wicomico County.

The fees called for are as follows:

> "Trucks weighing less than 3 tons, carrying capacity included, 1/10 cent per ton-mile, multiplied by the total number of miles which the application for the license shows will be traveled by the truck during the year for which the license is issued.
>
> "Trucks weighing over 3 tons and not more than 6 tons, 1/8 cent per ton-mile, multiplied by the total number of miles to be traveled by the truck during the year for which the license is issued.
>
> "Trucks weighing over 6 tons and not more than 12 tons, 1/6 cent per ton-mile, multiplied by the total number of miles to be traveled during the year for which the license is issued."

A 5-ton truck, with its load, would certainly weigh more than 6 tons. Five trips, with 5 tons each, 5 load miles each, would equal 125 ton-miles per day. At the rate given, 1/6 cent per ton-mile, the tax would be $0.208333 multiplied by the yearly mileage. Assuming 300 days of operation at 50 miles each, this would be 15,000 miles per year, and $0.208333 × 15,000 = $4,124.99½.

Bill Is Discriminatory

Needless to state, the passage of this law would be tantamount to prohibiting the operation of trucks in the State of Maryland, in such service, which includes not only inter-city express trucks, but also trucks and delivery vehicles making interurban or suburban deliveries. Furthermore the income which would otherwise be derived from taxation of these vehicles would be forfeited. Besides this the bill is obviously discriminatory against a class of vehicle, inasmuch as a tire width of 1 in. per 500 lb. of weight is unreasonable. Other states have laws prescribing 750 lb. per inch of width; others 800 lb.; still others 1000 lb. The ordinary wagon tire, besides greatly exceeding these figures, is composed of steel and is therefore still more injurious to the road.

Hydraulic Steel Cuts Melon

CLEVELAND, OHIO, March 25—The directors of the Hydraulic Pressed Steel Co., this city, recently decided to issue the remaining $155,000 capital of its total authorized issue of $1,000,000 to present holders of the common stock at $150 per share.

Action was also taken to increase the capital stock of the company, from which a 50-per cent dividend will be declared.

The present outstanding common stock amounts to $845,000. Shareholders of record as of the close of business March 7 will have the right to subscribe pro rata to the 15,500 shares now in the treasury. This will represent an allotment of 18.34 per cent at $150 a share. Subscriptions are made payable March 20.

The company will realize $232,500 from the paid-in stock, which will partly reimburse the treasury for an outlay of $600,000 which has been made in the way of extensions of plants during the past six months.

The gross business for the year 1916, exclusive of the output of munitions, will amount to between $3,000,000 and $4,000,000.

Hupp Declares Regular Dividend

DETROIT, March 25—The Hupp Motor Car Corp. has declared its regular quarterly dividend of 1¾ per cent on the $1,500,000 of 7 per cent preferred stock, issued last Fall. The dividend is payable April 1 to stockholders of record March 20.

$200,000 for Old Lozier Co. Creditors

DETROIT, MICH., March 25—A dividend of 7½ per cent, representing about $200,000, has been mailed from the offices of referee in bankruptcy, Lee E. Joslyn, to creditors of the former Lozier Motor Co., which has no connection whatever with the present new Lozier organization in this city.

Thus far four dividends have been declared, two of 5 per cent each, one of 2½ per cent and the present one of 7½ per cent, and the total paid to creditors is about $700,000.

Saxon Ships 179 in 1 Day

DETROIT, MICH., March 27—The Saxon Motor Car Co., broke its former record for one-day shipments on March 16, when 179 Saxons were shipped.

Manitoba Car Market Booming

Dealers Report Unprecedented Sales—Consignments May Total $1,000,000

WINNIPEG, MAN., March 27—A big trade is being done among the car dealers in Manitoba this spring, especially in medium-priced cars. All the dealers report unprecedented sales, one shipment from the East the other day representing over $200,000. The cars were sold in the provinces of Manitoba and Saskatchewan. This was only about one-third of the consignment which is to follow later.

There are at present 9206 cars in use in Manitoba. Placing an average price on these of $1,000 it represents a capital of nearly $10,000,000 in the single province of Manitoba. There is, in addition to this, probably two-thirds as many in Saskatchewan and about the same number in Alberta. The prairie provinces, therefore, represent probably the biggest market for motor cars in Canada, if not in America.

There are 4201 cars owned in the city of Winnipeg, the balance being distributed in various points in Manitoba as follows: Brandon, 371; Portage La Prairie, 149; Neepawa, 81; Carberry, 65; Deloraine, 53; Minnedosa, 60; Virden, 47; Melita, 45; Stonewall, 33; Morris, 20; Emerson, 29; Carman, 65; Cartwright, 22; Gladstone, 32; Glenboro, 26; various municipalities, 3487; by dealers, numbers set apart, 400; by Manitoba Government telephones, 20. Total, 9206.

Hartford Auto Parts Doubles Capital

HARTFORD, CONN., March 25—The Hartford Auto Parts Company, Hartford, Conn., has decided to remain in Hartford and will make use of the New Britain location as a branch. The company is now quartered in the old Cheney silk mill, where the Kelsey motorette was formerly made. The stockholders of the company have decided to double the capital, increasing the stock from $300,000 to $600,000. This concern has come along well within the past year and is now operating 24 hours a day. It is expected that the New Britain branch will be in operation by the first of July.

New Plant for Laporte

SOUTH BEND, IND., March 25—The Portable Power Mfg. Co., Chicago, has decided to move its plant to Laporte, Ind., it will occupy a part of the building of the Laporte Carriage Co. The concern makes a specialty of light and low-priced gasoline engines, such as a motor adapted for use on a grain binder or mounted on a light base and used for any sort of work the gasoline engine is adapted to on the farm.

The contractor is putting the concrete roof on the building just east of the main office at the plant of S. F. Bowser & Company, Fort Wayne, Ind., and it is expected to complete the building and have it ready for occupancy by April 1. This building which is absolutely fireproof is 40 by 60 ft. in dimensions and five stories high. The lower floor will be used for a dead storage vault and the upper floors will be used for offices.

Better Business Dept. for Chalmers

DETROIT, MICH., March 27—For the betterment of its dealers the Chalmers Motor Co. has instituted a Better Business Department and has promulgated an accounting and business system for dealers. The operation of the system is backed up by the Chalmers company, which proposes to stand behind it and assure its satisfactory operation in the places of business of those dealers and distributors who install it.

The system comprises a complete set of forms, including such details as inventory cards, shop work order tickets, material requisitions and providing also ledger forms, a check register and everything required for an extensive system.

With the system goes a book in which are described all the different accounts and operations. It cites the operations in daily routine, weekly routine and monthly routine. There are forms for balances and profit and loss accounts.

Chalmers Factory Men Dine

DETROIT, MICH., March 25—The Chalmers Motor Co. entertained at a banquet to-night a number of superintendents, foremen, inspectors and other factory employees connected with the motor assembly, block test, tuning and repair departments. As in the case of similar banquets where the men higher up from other Chalmers departments are invited, the object is to bring about closer fellowship and discuss matters of general interest relative to the particular departments. Vice-president and general works manager S. H. Humphrey presided at the banquet.

Receiver for Toledo-Findlay Tire

FINDLAY, OHIO, March 25—The Toledo-Findlay Tire & Rubber Co., a concern having a capital of $300,000, has been placed in the hands of a receiver upon the application of A. O. Hamilton, Charles Reick, V. T. Spitler and Henry Hard, directors. The concern was previously known as the Toledo Ford Tire Co., and makes tires especially for Ford cars.

50 Per Cent Gain In Southwest

Cadillac Representatives in That Section Meet at Dallas—Predict Boom

DALLAS, TEX., March 27—The sale of motor cars in the Southwest during the 1916 season will be 50 per cent greater than last year, according to the sentiment expressed at the first annual conference of Cadillac southwestern representatives in this city, March 20 and 21. The dealers came from Missouri, Kansas, Oklahoma, Texas, and parts of Louisiana and Arkansas. They were guests of R. L. Munger, the company's representative in this city.

The increasing prosperity in the South and the optimistic reports from the various commercial centers in Texas, Missouri, Kansas, Oklahoma and parts of Arkansas and Louisiana were among the topics discussed during Tuesday afternoon. Wednesday the discussion of these conditions continued and the salesmen and dealers concluded their meeting more optimistic than when they came.

Those attending the meeting were: E. C. Howard, sales manager, and L. M. McNaughton, assistant sales manager, both of Detroit; George H. Gaston, Detroit; R. C. Greenlease and H. H. Pierce, Kansas City; F. B. Callender, Wichita, Kan.; M. E. Swinney and W. W. Tillman, Springfield, Mo.; H. Perry, Detroit; D. D. Wetzberger, Tulsa, Okla.; J. D. Burrows and C. C. Jones, Oklahoma City, Okla.; Joseph H. Roberts, Enid, Okla.; P. P. Kearney, Ardmore, Okla.; Miles G. Bivens and W. Crossett, Amarillo, Tex.; J. G. Spaulding, Abilene, Tex.; Ed G. Hall, Brownwood, Tex.; H. G. Staacke, San Antonio, Tex.; C. F. Gydeson, Houston, Tex., and J. W. Sanders, Shreveport, La.

Union Tire and Rubber Co. Incorporated for $500,000

ST. LOUIS, MO., March 25—The Union Tire and Rubber Co., recently incorporated in Delaware with a capital of $500,000 to manufacture automobile tires, has acquired the former plant of the Banner Rubber Co., at Kenrick and Bittner Streets, this city. The plant has a frontage of 252 ft. on Kenrick Street.

Fried Joins Premier

INDIANAPOLIS, IND., March 28.—E. R. Fried, at one time connected with the engineering department of the General Motors Co. and the Ferro Foundry and Machine Co., having more recently acted as assistant chief engineer of the F. I. A. T. Co., has been appointed assistant to C. S. Crawford in the engineering department of the Premier Motor Mfg. Co., this city.

Kemco Electrical Co. Reorganized

Entirely New Ownership and Personnel—Officers and Board of Directors Elected

CLEVELAND, OHIO, March 27—The Kemco Electrical Mfg. Co. has been reorganized with an entirely new ownership and personnel. C. A. Burrell, for a number of years credit and advertising manager of the Willard Storage Battery Co., has been made secretary and general manager. The other officers are: President, Frank W. Glass; vice-president, E. M. Silver; treasurer, A. O. Silver. The three latter are from Salem, Ohio. The Silver brothers practically own the Silver Mfg.. Co. of Salem. The directors will be the four officers and H. E. Silver, also of Salem. Under the reorganization none of the old Kemco officers or directors remain. The company will specialize in the manufacture of starting and lighting equipment for Ford cars, which it has been making for some time.

Splitdorf Co. Pays Back Dividend of 7 per Cent

NEWARK, N. J., March 27—The Splitdorf Electrical Co. has declared a dividend of 7 per cent, which represents dividends in arrears. This leaves 19 per cent in back dividends remaining to be paid off. It is expected that the remaining back dividends will be paid off within the next four months.

Market Prices Steady

NEW YORK CITY, March 28—With the exception of a large rise in lead, market prices last week were on the whole very steady. Bessemer and open-hearth steel remained constant at $45 per 100 lb. Lead, however, continued on its record-breaking rise, reaching $8.18 yesterday, recording a jump of 30½ cents per 100 lb. for the week. This metal rose 12½ cents the previous week. Copper is holding firm with fair buying at 28½ cents a pound. Aluminum and antimony were slightly firmer yesterday with a large demand. Aluminum is now selling at 65 cents a pound, while antimony is quoting at 44½ cents.

A somewhat firmer tone developed in the market for crude rubber yesterday, although prices did not show much change. Business in the local market was more active. Mail advices from London state that the market for crude rubber has fluctuated moderately, but that its undertone has been on the whole good. The quantities actually available or left unsold are rather light, and there is a nervous feeling among those who have to secure deliveries against outstanding contracts, while importers maintain a reserved attitude, being apparently inclined to hold back a little stock pending developments. The price of hard Para is at present comparatively low, and therefore should tend to attract a better demand. Up-river Para is now quoting at 75 cents, while Ceylon first latex is steady at 91 cents.

The oils and lubricants prices were for the most part very steady with few changes. Linseed oil dropped 1 cent a gallon to 77 and cottonseed oil declined 25 cents a barrel to $10.70. Gasoline is still quoting at 24 cents wholesale with threats of a further rise to about 30 cents. No credence is given to the reports of 40-cent gasoline.

Firestone and United States Tire Companies Out of Tire Suit

CLEVELAND, OHIO, March 24—Holding that there was not sufficient evidence to support a charge of conspiracy against them, United States District Judge Killitz, sitting here, released the Firestone Tire & Rubber Co., Akron, and the United States Tire Co., New York, as defendants in a suit involving $1,000,000 alleged damages sought by the Automobile Co-Operative Association of America, which claimed to have been put out of business and its capital dissipated.

The suit against the B. F. Goodrich Co. and the Diamond Rubber Co., Akron, and the Republic Rubber Co., Youngstown, which were alleged to have been in the conspiracy charged, was proceeded with.

Flint Varnish & Color Works of Canada Formed with Capital of $250,000

FLINT, MICH., March 23—Officials of the Flint Varnish & Color Works announce the formation of the Flint Varnish & Color Works, Ltd., of Canada, capitalized at $250,000. The Canadian plant will be located in Toronto, in the factory buildings formerly occupied by the Dominion Carriage Co., and which consist of a three-story building, 250 by 82 ft., and a one-story building, 250 by 60 ft. A one-story structure, 120 by 120 ft., will be erected for melting, thinning and treating gums used in the manufacture of varnish.

Gilbert Mfg. Co. Winner in Tire Cover Suit

NEW HAVEN, CONN., March 25—Editor THE AUTOMOBILE:—There is some confusion in the trade concerning the decision of the United States circuit court of appeals in a suit of the Allen Auto Specialty Co., against our former New York representative, E. G. Baker. Your news item in THE AUTOMOBILE for Dec. 23 seems unfair to us in that it implies further proceedings in this matter and makes no mention of our connection with this suit.

We wish to make it clear that the decision was in favor of the Gilbert Mfg. Co., Mr. Baker merely figuring in the suit as our New York representative.—E. B. Spaulding, Gilbert Mfg. Co.

U. S. Rubber Officers Re-elected

NEW YORK CITY, March 23—The newly elected board of directors of the United States Rubber Co. met to-day for organization and elected the following officers: President, S. P. Colt; vice-presidents, J. B. Ford and Lester Leland; vice-president in charge of development work, R. B. Price; vice-president in charge of mechanical department, E. S. Williams; assistant to president, J. N. Gunn; secretary, Samuel Norris; assistant secretary, J. D. Carberry; treasurer, W. G. Parsons; assistant treasurer, E. J. Hathorne.

Winding Up Streator Affairs

STREATOR, ILL., March 27—Sidney C. Eastman, referee in bankruptcy, is making an effort to wind up the affairs of the Streator Motor Car Co., a number of modern buildings suitable for a manufacturing plant, and seven acres of land contiguous being included. Bids were received by the referee at his office, 907 Monadnock Block, Chicago, March 28. All creditors have received notice of the proposed sale and that they will be per-

mitted to file objections at a hearing before E. U. Henry, referee in bankruptcy, at his office in Peoria, Ill., on March 31. The plant is now occupied by A. C. Barley, who has formed a new company for the manufacture of automobiles. He has a lease and owns the equipment but not the buildings. It is presumed that Barley will be one of the bidders.

—

Twin City Four Wheel Drive Mfg. Co. Incorporated

ST. PAUL., MINN., March 25—The Twin City Four Wheel Drive Mfg. Co., which is completing a plant at University and Cromwell Avenues, has filed incorporation papers, putting capital at $1,000,000. Officers are: President, D. W. Henry; vice-president, J. E. Hayes; secretary, J. R. Hayes. Other incorporators are C. W. Kelly and C. W. Guilder. The first meeting will be April 4. The company makes the Ware truck.

—

United Truck Sales 50 per Cent Better

GRAND RAPIDS, MICH., March 25—During the first half of March the sales of the United Motor Truck Co. were 50 per cent in excess of the sales of the month of February, which was itself 119 per cent better than January.

—

Frost and Merriman on Jackson Board

JACKSON, MICH., March 24—At the annual election of directors for the Jackson Chamber of Commerce, E. J. Frost of the Frost Gear & Machine Co. and Mark Merriman of the Hayes Wheel Co. were elected to the board of directors.

Security Prices Lower

—

Overland, Studebaker, and Maxwell Common Issues Show Decline

NEW YORK CITY, March 28—Automobile issues were erratic last week and prices were much lower. Up to the previous week prices were generally steady and higher. Chevrolet and Chalmers this week continued their rise of last week, while those stocks which have shown strength throughout this month suddenly dropped from 1 to 10 points. Chevrolet closed on Saturday at 164, a record price, while Chalmers closed at 158, having risen 8 points during the week.

Though Maxwell common dropped 3½ points, the stock has shown much strength, due to expectation of larger earnings after April 1. During the early part of last week Maxwell issues were very prominent in the market.

There was little activity in General Motors stocks, the common remaining unchanged and the preferred going down ½ point. It is expected that the directors of that company will meet to take action on the dividend during the first week of April.

Studebaker common and preferred dropped 5 and 2 points, respectively. It is believed that net earnings of this corporation for the quarter ending March 31 will be around $3,000,000. It will be recalled that on March 1 Studebaker paid off from the treasury resources the last of its notes amounting to $2,305,000, so that this year all profits accrue directly to the preferred and common stocks. The preferred dividend takes less than $770,000 yearly.

Detroit issues were steady, with a few substantial gains. Canadian Ford and Paige-Detroit featured with rises of 45 and 10 points, respectively. Maxwell common and second preferred were also strong, with 6 and 6½-point rises. The rise in Canadian Ford may be attributed somewhat to the report that the Canadian government will not make the special war tax as drastic as it was first announced, and that the Ford company will thus not have to pay $2,000,000 or more. Reports also have it that the business of the company has been much better than was anticipated and the demand in that country continues to be such a very good fiscal year is assured.

There has been quite a bit of trading in Maxwell stocks, brokers having received reports indicating that the concern is doing exceptionally well. There were some transactions in Kelsey Wheel stock, which caused this stock to rise 15 points, bid, and nearly 100 points asked. There were a few sales of Paige-Detroit stock at 725, or 35 points better than the previous sale of the stock. General Motors shares were sold at 485.

—

Dividends Declared

Gray & Davis; quarterly of 1¾ per cent on preferred, payable April 1 to stock of record March 2.

Kelly-Springfield Tire Co.; quarterly of 1½ per cent on 6 per cent preferred, payable April 1 to stock of record at close of business March 18.

Burman Wins at San Diego

Peugeot Covers Freakish 50-Mile Course at 52.14 M.P.H. —38,000 Spectators

Exposition Grounds, San Diego, Cal., March 25—Bob Burman in the Peugeot won the freakiest race of his career today when he captured the Exposition cup race before a crowd estimated at 38,000.

The race on the Exposition Grounds this afternoon was the first boulevard race ever run under the sanction of the A. A. A. and it will probably be recognized as a world's boulevard race record, at least until the Corona classic is run, April 8.

Considering the nature of the course, the time made was remarkable. Burman covered the 50 miles at a speed of 52.14 m.p.h., in 57 min., 30 4/5 sec. Teddy Tetzlaff, on the Los Angeles-built Milac, was second to get to the checkered flag, his time being 58 min., 20 2/5 sec., or 51.42 m.p.h. Barney Oldfield on the Delage finished third, doing the distance in 59 min., 15 sec., or at 50.58 m.p.h., and Cliff Durant on the Durant Special crossed the line after driving 1 hr., 2/5 sec.

An Early Mix-up

On account of the many turns and the narrowness of the course only four cars were allowed to start. On the opening lap, Durant, Tetzlaff and Burman overran a turn and tangled up in the safety zone. Durant's car suffered the most damage. He broke several spokes out of a rear wheel and bent his frame; but after changing the wheel and incidentally losing two laps, he continued in the race and made up a lap before the end of the 50 miles.

Oldfield jumped out in the lead on the first lap and while the drivers were getting back on the course after the near-disastrous affair on the curve, Barney stepped half a lap to the good on Burman and Tetzlaff. On the third lap Barney jarred his oil line loose and for the rest of the race he and his mechanic had to ride through a spray of lubricating fluid. The leaky oil line spoiled Barney's chances for first money and had not Durant lost two entire laps, Barney would have been the last to get to the checkered flag. He knew that he could not stop and repair the damage without losing at least two laps and, therefore, kept up at the best speed possible and gradually dropped back as Burman and Tetzlaff forged ahead.

The arrangements for the race were as novel as the course was freaky. The home of Bosco the snake-eater was used as the judges' stand. The pits were located in an animal cage, vacated for the afternoon on account of the races, and the official grandstand consisted of several hundred benches placed on the main street of Grizzly Gulch, the famous '49 camp.

After Burman passed Oldfield in the fourth lap he held the lead all the way to the finish, although Tetzlaff threatened to overtake him several times on the curves.

Four Entries for Sheepshead Bay May 23 Races

New York City, March 28—Ralph Mulford has entered his Peugeot in the 150-mile Metropolitan Trophy race to be run at the Sheepshead Bay Speedway on May 23. Three Crawford specials have also been entered. These will be campaigned this year by William Chandler. The cars are equipped with sixteen-valve Duesenberg four-cylinder motors. The dimensions are 3¾ by 6¾ in. Chandler will drive one and the others will be handled by Dave Lewis and Art Johnson.

N. G. N. Y. Motor Battery Ready in September

New York City, March 28—Although the first armored motor battery in service in this country was mustered into the service of the National Guard of New York recently at the armory of the Twenty-second Engineers, here, the vehicles will not be completed until next fall, probably next September. Two of the vehicles have already been completed, these being the Jeffery four-wheel-driven service truck and one of the armored Locomobile chassis.

The equipment for the battery will cost in the neighborhood of $100,000, and is in charge of A. F. Masury, chief engineer of the International Motor Co., at whose Metropolitan service station the work is being carried on. The funds have been donated by Elbert H. Gary, Henry C. Frick, James N. Wallace, Dudley Olcott II, Col. William F. Thompson and Lieut. Harry G. Montgomery who will command the outfit.

The company will be mustered into service by Lieut.-Col. N. B. Thurston, chief ordnance officer of the National Guard of New York, and will consist of college men of the type who attended the Plattsburgh encampment last summer. There will be 162 men in the company, commanded by Lieutenant Montgomery, who will be commissioned as Captain, two first lieutenants, three second lieutenants, twenty sergeants, thirty-six corporals and 100 privates.

Inter-State Has a Drive-away

Muncie, Ind., March 25—One hundred and seventy-six distributors, dealers and buyers from Indiana and Ohio drove away from the Inter-State factory last week with 150 new cars. The drive-a-way was originated by George Kanouse, Indiana distributor. A banquet was given Wednesday evening, at which the principal address was made by General Manager B. W. Twyman of the Inter-State company.

Funston Asks for More Trucks

Washington, D. C., March 27—General Funston has sent a hurry call to the War Department for two additional motor trains. This is due to the extension of the line of communication a distance of over 200 miles below the border. The Fifth Cavalry which was ordered to the border a week ago has been sent into Mexico to protect the lines of communication. It is stated that General Funston's request was based upon the excellent work being done by the trucks in Mexico at the present time and that he asked for Jeffery trucks, their four-wheel drive adapting them to the road conditions, which are bad and getting worse.

It is stated that these two companies have already been purchased by the War Department.

De facto President Carranza of Mexico is showing a strong disposition to delay the granting to the American forces of the right to use the Mexican railroads and in some quarters it is thought the permission will not be granted at all. At all events the expedition cannot wait for the negotiations to be completed, as some of the cavalry regiments are stated to be on short rations now. For this reason General Funston will be supplied with sufficient motor transportation equipment to make him independent of the railroads in Mexico.

Packard Preparedness Proved

Detroit, Mich., March 23—Readiness to aid the government in time of need was demonstrated by the Packard Motor Car Co. in filling a special order for a motor truck transport company similar in organization to those recently filled by the White and Jeffery companies. In less than 22 hr. after the receipt of the order, Monday night, March 20, for twenty-seven trucks for the use of the Quartermaster Corps in Mexico, a special train of fourteen steel freight cars and one Pullman left the factory with the right of way to Columbus, N. M. The train carried the complete company of the trucks and thirty-three recruits for the service.

The train was scheduled to make the trip to the Mexican border in 51 hr. The recruits were secured by calling a mass meeting in the Packard shops. It is said that 1000 men volunteered. When the thirty-three were selected, they were given 6 hr. to pack their belongings into small handbags, settle their business affairs and report at the train.

A special night shift was put onto the job of constructing the trucks 2 hr. after the order was received.

50,000 at Pittsburgh Show

Steel and Munitions Boom Renders Territory Prosperous —Expect Big Sales

PITTSBURGH, March 28—The twelfth annual show of the Automobile Dealers' Association of Pittsburgh in Motor Square Garden, East End, which closed March 25, has been an exceptional exhibit in several ways. First, the attendance has broken all previous show records. It is estimated that during the seven nights and six afternoons of the show more than 50,000 different people visited Motor Square Garden.

In the matter of displays this show also took a front rank. Over 300 cars were on exhibit, representing seventy-one different makes. Chief interest centered in the twelves and eights. A considerable number of these were sold right from the Garden. The display of accessories was larger than for several years. Accessory manufacturers have been a little shy the past two years about investing their money, but this year they came forward strongly and there was a large number of exhibits.

Friction Avoided

The management of this show succeeded in putting in a show without any friction such as has characterized the show situation in this city for the past few years. Letters were sent out to more than 1200 dealers in tri-State territory, and a very large proportion of these dealers attended the show. In fact, the interest shown by dealers this week has been far and away the most encouraging feature of the show. It was reported to-day that nearly 100 cars had been sold up to this date, and it is expected that with to-day's sales this number will be considerably increased. Many dealers from outlying points have picked out their favorite cars at the show and have arranged for an allotment of from four to six cars.

The 1200 dealers in tri-State territory, most of them located within 40 miles of Pittsburgh, are looking for very much the best season that they have had for years. The reasons for this are not hard to find. Last year Pennsylvania had very abundant crops, and farmers have been prospering beyond the average on account of this fact and the higher prices which they are receiving for their products. This makes it certain that sales by country dealers will be very much larger than for a long time.

Steel Boom Means Sales

Coming nearer to the city, there is the unprecedented activity in the steel business as a sure forerunner of big sales this year. All steel records have been broken during the past few months. The total number of men employed in the steel mills in the immediate Pittsburgh district would probably be at the present time between 55,000 and 60,000. This is exclusive of all other manufacturing plants which are allied with the steel interests, and shows why the payrolls in this district are now running at a total of more than $1,3000,000 per day, according to bank statements.

Wages are being raised in all the big plants throughout this section.

Bank clearances in this district are running from $1,000,000 to $1,500,000 per day more than the corresponding days of 1915. Added to this is the still more encouraging fact that activity in the steel industry is assured for the entire year. Bookings are now being made in many lines for 1917 delivery. A few of the big concerns in the Pittsburgh district are sold up to late in the fall, and many of them to Jan. 1, 1917. It is to be noted, also, that the average price of steel products, taking the entire list, is $20 per ton higher now than the average of the past ten years.

In the coal and coke industry there is also enormous activity. Coke ovens are running at about 96 per cent or 98 per cent capacity. Coal mines throughout the tri-State territory are doing nearly as well. The question of getting labor is becoming a very serious one, owing to the large number of foreigners who went back to Europe to fight.

In all machinery plants and munition factories it is a hard problem to get enough men to equip the plants. The Westinghouse Electric & Manufacturing Co. is employing by far the largest total of men in its history. Other smaller concerns have similar reports to make. The scarcity of labor in this territory has not been so great for ten years as now.

Hills No Handicap

All this means that there is an enormous amount of money in circulation in the Pittsburgh district and throughout western Pennsylvania, eastern Ohio and West Virginia. Dealers are going to get a large amount of it. The popularity of the motor car was never so great as it is to-day. The feeling that Pennsylvania hills were not made for automobiles has been entirely dissipated.

Dealers report that sales since Jan. 1 are more than double what they were for the first three months of last year. Some agencies have a much better gain than this to report. One organization, for instance, sold four cars in January of 1915 and twenty-six in January of this year. The February and March totals will be in about the same ratio, and the company announces that its sales for three months will be at least four times as large as in 1915. Not only the high-priced cars, but especially the low- and medium-priced cars, are going to make enormous gains in their sales this spring.

The total number of owners in Allegheny County is estimated at 14,000, and in tri-State territory this number would probably come up to over 20,000. There is only one consideration that is going to cut down the sales of cars this year. This is the high price of gasoline. This, according to well-posted dealers, is not likely to affect seriously buyers of cars costing from $3,000 up. It will, however, make a considerable difference probably in the sales of cars ranging in price from $500 to $1,500, and already this factor has spoiled many sales.

May Abandon Danville Show

DANVILLE, ILL., March 27—Being unable to find a building in Danville large enough to accommodate the proposed automobile show of the Automobile Dealers' Association of Danville and eastern Illinois, it was found necessary to ask the City Council to permit the use of Van Buren Street between Hazel and Jackson Streets. The Council, after long debate, denied the petition on the ground that the city would be responsible for any damage that might accrue from the blocking of the thoroughfare. The dealers are now trying to find a lot suitable. If unsuccessful, the show will be abandoned.

Motor-Power Show Soon

SAN FRANCISCO, CAL., March 28—The first annual Pacific Coast Motor Power Show has been scheduled to take place April 26 to May 6 in the new $1,000,000 municipal auditorium of Oakland, Cal. Some 50,000 sq. ft. of floorspace will be occupied by the exhibition. The Lincoln Highway Assn. is interested in the enterprise and L. E. Warford, Pacific Coast representative of the association, is acting as secretary of the show. All types of gasoline-propelled vehicles will be exhibited, including motor trucks and tractors.

Ninth Market Report Coming

CHICAGO, ILL., March 27—In its ninth edition of the National Used Car Market Report the Chicago Automobile Trade Association plans to make the issue more comprehensive than any that has previously appeared. Letters are now being sent to subscribers and also to non-subscribers, urging that the used car prices be placed in the hands of Assistant Secretary T. D. Beard by April 1. The sales asked for are those occurring between Dec. 21 and March 21.

Originally the secretaries of local associations were requested to collect the reports of sales in their cities, but it has been found facilitating to have the information sent by the individual dealers, and this plan is now being followed.

South American Market Needs Delicate Handling

Great Care with Exports Reason of European Success in Southern Continent

UNLESS American manufacturers are willing to transact business with the South American countries on a credit basis, unless they are willing to ship goods as ordered, so that they will reach their destination in good condition, and unless an American merchant marine is established, there is little prospect that after the European war the United States will receive the large business that it could get from South America.

This is the opinion of Peter S. Steenstrup, South American sales representative of the Hupp Motor Car Corp., who returned recently from his third trip to South American ports, during which he investigated present conditions and the future trade possibilities in Argentina, Brazil, Peru, Chile and the West Indies.

Speaking from the point of view of the automobile business, Mr. Steenstrup believes that there will be an increasing demand for American-made cars, especially of medium price. The wealthy class will continue to purchase expensive European cars, to a limited extent, even used cars of European origin in preference to the American car.

Credit Is Essential

The most serious obstacle in connection with our trade expansion in South America is the matter of credit, says Mr. Steenstrup. The merchants, manufacturers, and in fact everybody doing an import and export business, have been and are still operating on a credit basis with Europe. Just now some do business on a cash basis with America because they cannot help themselves, for otherwise they could not get the goods they need. However, as soon as the war is over these importers will again renew their commercial relations with Europe, especially with the German concerns with which they have done business formerly.

This is because they have the assurance that they will continue to be given credit by these German concerns and because that is the only way they want to do business. Practically ever since there has been business intercourse between South America and Europe, it has been on a credit basis and this custom is now national and will not be changed.

Another reason why Europe will most likely again receive the bulk of the South American trade after the war is that the manufacturers of Europe, and especially of Germany, have always been most careful in sending the goods ordered the way they were wanted, that is, packing them carefully and seeing to it that shipments are handled with great care.

Careless Shipping Does Harm

Mr. Steenstrup further complains that American manufacturers do not seem to be willing to follow either the wishes of the South American firms as to what they want, but also are careless in shipping goods. Thus shipments coming from the United States very often arrive in a most unsatisfactory condition, sometimes broken up, sometimes with part of the contents missing, because of the poor and insufficient packing material used. In many instances, also the shipping documents are faulty or incomplete, which often causes long delays and extra expense. But above these great mistakes and evidence of carelessness, is the fact that often the goods shipped are not what was ordered, but something "just about" what was wanted.

European concerns do not do this, and in case they would have to make a substitution, they either write or cable the fact and await instructions. "In a word," says Mr. Steenstrup, "from what I saw and heard, it seems that the American manufacturer really does not want to go to the trouble to take care of his export business in the right way. He often has not the kind of competent men needed to attend to the export end of the business and does not seem to think seriously enough about the matter."

The lack of direct American shipping facilities, in other words, the fact that the United States has no merchant marine, has always been and will continue to be one of the greatest obstacles in the way of the trade expansion of this country with South America.

Business men and government officials find it extraordinarily strange that the United States, with its tremendous export business, is unwilling to provide itself with American-built ships, for direct trade connection with South America. The fact that most goods exported from the United States come in either British or German bottoms instead of American ships, has been and will be exploited to good advantage by the European manufacturers and exporters, with their customers in South America and, as long as this condition prevails the importers in those countries will continue giving their business to Europe.

Money Values Fall

Conditions at the present time are not any too good in South America, except in Argentina. This is the only country where money exchange has not fluctuated and where the national finances are in good shape. All other countries are deeply in debt, owe much money abroad and must keep on borrowing due to the shortage in revenues.

In Brazil, for instance, the value of the milreis, which before the war was 32 cents in American money, has dropped to 24 cents. This means that everything costs one-third more in our money; that an automobile, for instance, which could be purchased for $1,000 before the war, now costs at least $1,300, although identical in construction and equipment. In Chile the peso was worth 18 cents gold before the war. Now it is worth 15 cents gold, and this may drop to 14 cents.

There are at the present time probably about 40,000 automobiles in all South America, and a large percentage of them are in Argentina. In this country touring is enjoyed to a small extent, while in the other countries the roads are generally impossible beyond 10 or 20 miles from the larger cities.

A feature which has impressed Mr. Steenstrup is that nearly all South American countries have excellent trade promotion systems and many very competent trade advisers. The governments spend much money for extensive investigations in foreign countries for the purpose of learning where products of South America can best be sold and where it is best to purchase goods needed. Close business relations are established with Europe and there is a constant interchange with a view to a better understanding and improving trade. Competent men are sent to Europe and they make thorough investigations on the ground, and usually obtain good results.

The History of the American Automobile Industry—23

(*Continued from page* 593)

four cycles of operation. His conception of the different operations is clearly set forth in his patent. Here is how he expressed it:

"It will be seen that there are four strokes of the piston required for one complete operation, namely: an outstroke for drawing in the charge of combustible mixture and air, an instroke for compressing the gases, a second stroke when the piston is propelled on the ignition of the gases, and a second instroke for expelling the products of combustion. The slide valve *V* consequently has to perform one to-and-fro motion while the piston is performing these four operations."

Otto Type Supersedes Brayton

If we compare the Otto engine with the Brayton two-cycle engine of last week, which was its great predecessor, it will be readily seen that the compressed air in the Brayton engine lost heat in the compressing cylinder and in the storage tank or reservoir, and also in the pipes and valves leading to the cylinder in which it was exploded. Higher crankshaft speeds were also possible with the Otto type as constructed with the knowledge of that day, and therefore the Brayton engine not only disappeared from the market within the next ten years but air engines generally ceased to be a factor in motor vehicle work, although continued for many stationary purposes where small power was required, such as pumping water, until after the end of the century. That this disappearance is due to one of those waves of public opinion which we have seen so frequently recurring is more probable than that the air engine has been finally and fully superseded. They had many points of merit which may some day restore them to public favor, a fact to be noted in these days of multiple-cylinder engines.

The modern gas turbine is beginning to look very simple compared with modern automobile power plants, and some forms of it closely resemble the internal combustion idea introduced by Cayley more than 100 years ago and they show efficiencies nearly as high as did Lenoir's engines at the time of the Civil War.

Increasing the Thermal Efficiency of the Engine

(*Continued from page* 579)

50 per cent further than the induction stroke, but cutting off earlier as the load gets lighter, is shown at *GH*, while *IH* is theoretically the efficiency curve of a complete expansion engine, in which the compression is increased inversely, and the fuel directly as the load.

In solving the mechanical problem provision is made for retarding the beginning of compression when cranking, thereby introducing with the normal high compression no starting difficulties. A standard carbureter would require no change in adjustment for full load, but would require a fuel opening which would vary inversely with the amount of air induced. The fuel valve and cut-off lever would be connected together and operated by the accelerator pedal or hand lever on steering wheel. The rarefaction of the mixture in cylinder at full load induces expansion, gasification and a thorough commingling of the combustible molecules before compression, a condition which insures rapid ignition and perfect combustion.

While the thermal efficiency of complete expansion engines has been excelled only by engines of the Diesel type, there may arise unforeseen difficulties in increasing the compression inversely as the load, yet the possibility of developing an automobile motor whose thermal efficiency is at least 15 to 20 per cent higher than the best engines extant, and one in which the efficiency is as high at the partial load at which it is usually run as at full power, should be of vital interest.

Two of Several Chalmers Dealers' Meetings Last Week

Colorado Chalmers Dealers Hold Get-Together Meeting in Denver

DENVER, COLO., March 24—A bigger-and-better-business dinner for Colorado Chalmers dealers was held last night in the Savoy Hotel and attended by about thirty dealers from the State. The affair was arranged by E. J. Johnson, Chalmers distributor for Colorado and adjacent mountain territory, and by Frank B. Willis, general sales manager from the Chalmers factory. The dinner followed an afternoon meeting, conducted by the Chalmers representatives, but attended also by many local distributors and dealers handling other cars, the earlier meeting being for the purpose of promoting greater co-operation in the motor car industry throughout the Rocky Mountain district, improving efficiency of selling methods, display plans and general management of the business. Speeches were made by Mr. Willis, President W. W. Barnett of the Automobile Trades Assn. of Colorado, E. E. Sommers, president of the Colorado Good Roads Assn. and director of the Denver Motor Club; Frank M. Cochran of the Denver Maxwell agency, and President Thomas B. Stearns of the Chamber of Commerce. Visiting dealers reported favorable prospects for increased sales and for extensive road improvements and other community developments.

200 Chalmers Northwest Co. Representatives Meet in Minneapolis

MINNEAPOLIS, MINN., March 25—More that 200 representatives of the Chalmers Northwest Co. of Minneapolis attended a sales convention March 30-April 1 at the West Hotel. It was the last of a series by the factory company in the United States. Dealers were from Minnesota and the Dakotas. Paul Smith, vice-president, from Detroit, presided. Among the speakers were L. A. Van Patten, advertising counsel; F. B. Willis, sales manager, and Harry Miller, service manager. A banquet and a luncheon and motion pictures of the factory were on the entertainment list.

Factory Miscellany

Meteor Car Co. to Add—The Meteor Motor Car Co., Piqua, Ohio, will soon fit up part of its plant for the manufacture of automobile bodies.

Cowan Truck Increases Space—The Cowan Truck Co., Holyoke, Mass., has let a contract for the erection of a two-story 100 by 200-ft. factory.

North Dakota Co. Builds—The Missouri Valley Motor Co. is planning a three-story reinforced concrete plant. The estimated cost is $30,000.

Oklahoma Body Co. to Build—The Sharpe Motor Car & Body Co., Oklahoma City, Okla., will equip a plant for the manufacture of automobile bodies.

Niles Car to Make Trucks—The Niles Car Mfg. Co., Niles, Ohio, will add to its present line of products the manufacture of trucks and accessories.

Anderson Co. Taking Body Orders—The Anderson Motor Co., Rock Hill, S. C., in addition to manufacturing automobiles, is also making bodies for other concerns.

Stutz Begins Erection of New Addition—The Stutz Motor Car Co., Indianapolis, Ind., has begun the erection of a four-story addition, 70 by 204 ft., to cost $100,000.

Marion Tire Increases—The Marion Tire & Rubber Co., Marion, Ohio, will shortly begin the erection of a new plant which will include two concrete buildings, each 50 by 100 ft.

Warner Trailer Leases Plant—The Warner Auto Trailer Co., Beloit, Wis., has leased the J. Thompson's Sons Mfg. Co. plant and will begin operations as soon as equipment is installed.

Muskegon Concern to Enlarge—Additions necessitating an expenditure of $200,000, it is said, will be made to the foundry works of Campbell, Wyant & Cannon, Muskegon, Mich. This concern started in a very small way in 1909 with only a few employees. Today there are over 1100 men on its payroll.

Babcock Spring Co. Formed—The Babcock Automobile Spring Co., Milwaukee, Wis., has been incorporated with a capital of $15,000. The incorporators are C. Babcock, R. S. Babcock and W. J. McElroy. The plant is located at 192-194 Milwaukee Street, and specializes in the manufacture of automobile and other vehicle springs.

Polson Rubber Building Cleveland Plant—The Polson Rubber Co., Kansas City, Mo., maker of automobile tire accessories, on account of increase in business, is erecting a factory in Cleveland, Ohio, where it will make blowout patches, hook-on boots, reliners, etc. The new plant is under the personal supervision of H. B. Polson, and will be making shipments by Feb. 1. C. A. Polson will continue in charge of the Kansas City plant.

Victor Rubber Adds—Brick and concrete additions will be started in the near future at the Victor Rubber Co., Springfield, Ohio. The additions, five in number, will be one story high. They will practically double the production of the plant. The company employs about 400 persons at present. The new additions will make possible an increase of about 50 per cent in the working force.

Takes Over Superior Auto Parts Co.—The entire business, stock and good will of the Superior Auto Parts Co., Indianapolis, sole distributor of the R & M conform piston ring, has been taken over by the Modern Electric & Machine Co., that city. During the past year the Modern Electric company has added to its line the R & M aluminum piston and has enlarged its plant. T. A. Meyer is president and general manager of the company.

The Automobile Calendar

March 25-April 1	Wheeling, W. Va., Show, Market Auditorium.
March 27-April 1	Danville, Ill., Show, Eastern Illinois Dealers.
March 27-April 1	Johnstown, Pa., Show, Auditorium; Johnstown Auto Show Promoters. A. E. Oldham, manager.
March 27-April 1	Zanesville, Ohio, First Annual Southeastern Show, Airdome.
March 28-April 3	Manchester, N. H., Show, Under Auspices Couture Bros. Academy.
April 1-8	Butte, Mont., Home Industry Electric & Auto Show, Holland Arena, H. W. West, Mgr.
April 3-8	Twin Falls, Idaho, Show, Oliver Tabernacle, B. H. Fuller, Mgr.
April 8	Corona, Cal., 300-Mile Boulevard Race, Citrus Belt Racing Assn.
April 10-15	Seattle, Wash., Show, Arena.
April 12-15	Champaign, Ill., Show, Gymnasium Bldg., University, Ill.
April 14-16	Milwaukee, Wis., Garage-Circuit Exposition, Milwaukee Automobile Dealers.
April 15	Altoona, Pa., Pennsylvania State Motor Federation.
April 26-May 6	Oakland, Cal., First Annual Pacific Coast Motor Power and Automobile Show, Automobile Industries Assn.
May 6	Sioux City, Ia., Speedway Race, Sioux City Speedway Assn.
May 9-12	Hot Springs, Va., N. A. A. A. J. Meeting, The Homestead.
May 13	New York City, Sheepshead Bay Speedway Race. Metropolitan Trophy, 150 miles; Queens Cup, 50 miles; Coney Island Cup, 20 miles, and Brooklyn handicap for non-winners, 10 miles.
May 20	Chicago Non-Professional Speedway Race, Western Interclub Speedway Park.
May 26-27	Del Monte, Cal., Meeting, Three Divisions of National Assn. of Automobile Accessory Jobbers.
May 30	Des Moines, Ia., Iowa Derby, 20 Miles; Des Moines Special, 10 Miles.
May 30	Tacoma, Wash., 100-Mile Speedway Race, Tacoma Speedway Assn.
May 30	Indianapolis Speedway 300-Mile Race.
May 30	Minneapolis, Minn., Speedway Race.
June 10	Chicago Speedway Race. International 300-Mile Race, Speedway Park, Speedway Park Assn.
June 20	Galesburg, Ill., Track Race, 100 miles.
June 28	Des Moines, Iowa, Speedway Free-for-all. 300-mile race.
July 2-6	Detroit, Mich., World's Salesmanship Congress, Detroit Board of Commerce Bldg.
July 4	Coeur d'Alene, Idaho, Race Meet, Hilles-Riegel.
July 4	Tacoma, Wash., Speedway Race, Tacoma Speedway Assn.
July 4	Minneapolis 300-Mile Speedway Race.
July 4	Sioux City Speedway Race.
July 15	Omaha, Neb., Speedway Race.
July 15	North Yakima, Wash., Track Race, Riegel-Hiller Co.
Aug. 5	Tacoma Speedway Race, Tacoma Speedway Assn.
Aug. 11-12	Pikes Peak, Col., Hill Climb, Pikes Peak Auto Highway Co.
Aug. 12	Portland, Ore., Track Race, Riegel-Hiller Co.
Aug. 18-19	Elgin Road Race.
Sept. 4	Des Moines Speedway Invitation Race. Limited to six entries.
Sept. 4	Indianapolis Speedway Race.
Sept. 4-5	Spokane, Wash., Track Race, Inland Auto Assn.
Sept. 11-16	Milwaukee, Wis., Fall Show, Wisconsin State Fair, Milwaukee Automobile Dealers.
Sept. 16	Providence Speedway Race.
Sept. 29	Trenton, N. J., Inter-State Fair. H. P. Murphy, Racing Sec.
Sept. 30	New York City, Sheepshead Bay Speedway Race.
Oct. 7	Omaha Speedway Race.
Oct. 14	Chicago Speedway Race.
Oct. 19	Indianapolis, Ind., Race, Indianapolis Motor Speedway.
Nov.	Santa Monica, Cal., Vanderbilt Cup and Grand Prix Races.

The Week in the Industry

Cox Joins Overland—G. H. Cox, Kansas City district manager for Dodge Bros., has resigned to become the assistant director of branches for the Willys-Overland Co.

Welles Joins Overland—J. W. Welles has joined the Willys-Overland Co., Toledo, Ohio. He was formerly designer and general manager of the Matthews Boat Co., Port Clinton, Ohio.

Crooker Chalmers Assistant Advertising Manager—R. H. Crooker, who was advertising manager of the Regal Motor Car Co., Detroit, has been appointed assistant advertising manager of the Chalmers Motor Co.

Buller Liberty Advertising Mgr.—H. L. Buller has been appointed advertising manager of the Liberty Motor Car Co. He was formerly connected with the Oakland Motor Car Co., Pontiac, Mich., and the Apperson Bros. Co., Kokomo, Ind.

Boice Forms New Co.—W. S. Boice, formerly president of the Boice-Perrine Co., Boston, has organized the Boice Motor Equipment Co., Boston, located at 76 Brookline Avenue. This company is agent for the Vesta Accumulator Co. and the K. W. Ignition Co.

Bleiler Joins Miller Rubber—J. B. Bleiler, formerly vice-president of the Overman Cushion Tire Co. and for some years connected with the Diamond-Goodrich organization, has now joined forces with the Miller Rubber Co., Akron, Ohio, as manager of the solid truck tire department.

Lang Joins Detroit Gear—Currier Lang, who was chief of the civil engineering department of the Solvay Process Co. during the past eight years, has resigned to become assistant general manager of the Detroit Gear & Machine Co., Detroit, manufacturer of automobile transmissions and clutches.

Acton Joins Make-a-Truck—Leslie Acton, formerly treasurer of the Flanders Motor Co., has been elected vice-president of the British-American Sales Corp., 1708 Broadway, New York City. This company is engaged in the manufacture and sale of trucks and Make-a-Truck attachments for Ford cars.

Meers Goes to 'Frisco—I. B. Meers, assistant sales manager of the King Motor Car Co., Detroit, is now in the same capacity with the company's headquarters in San Francisco, for the purpose of taking charge of the King business on the Pacific Coast. R. V. Lull has taken Mr. Meers' place here at the King factory.

Motor Men in New Roles

Sohlinger Flint Varnish Sales Mgr.—W. J. Sohlinger has become sales manager of the Flint Varnish Works, Flint, Mich., succeeding A. W. Schaefer, recently resigned.

Bailey Joins Silver Staff—William Bailey, who has been connected with the automobile department of the New York Globe, will join the C. T. Silver Co., New York distributor of the Overland and Peerless.

Van Riper Joins Chalmers in Detroit—L. M. Van Riper has been appointed advertising manager and purchasing agent by the L. J. Robinson Co., Detroit, Michigan distributer for the Chalmers. Mr. Van Riper has for the last two years handled the automobile advertising for the Sprague Publishing Co.

Willard Men Move Up—S. S. Jenkins has been appointed district manager of the Willard Storage Battery Co., in the Detroit territory. He has been the manager of the Willard branch at Indianapolis ever since it was established. F. G. Tobin will be assistant district manager under Mr. Jenkins.

Join Steel Products Co.—G. V. Sevald, for fourteen years manager of the Cleveland office of the Detroit Copper & Brass Rolling Mills, and R. J. Scothorn, formerly manager of the Detroit office of the Columbus Bolt Works, have joined the Steel Products Co. selling organization in Cleveland.

Dealer

Overland Service Station in Memphis—The Memphis Overland Co., Memphis, Tenn., is planning a three-story service station and salesroom at Monroe Avenue and Lauderdale Street.

Hyatt Branch in Seattle—The Hyatt Roller Bearing Co., Detroit, Mich., will establish a direct service branch at Seattle, Wash., thus raising the number of its branches to ten. D. B. Bevier will be in charge at the starting of the new branch. Mr. Bevier was former service manager of the company's branch at Los Angeles, Cal., has been made district manager for all the Hyatt branches on the Coast. J. J. Hanrahan, formerly service manager at San Francisco, has been transferred to Los Angeles, and F. B. Brunton has been made service manager at the San Francisco branch. The Seattle branch will be formally opened about the first of April.

Caister Becomes Sales Mgr.—E. E. Caister has become sales manager for Al. C. Faulkner Co., Inc., Los Angeles, Cal., southern California distributor for Marmon cars. Mr. Caister was for nine years sales manager for the Earl C. Anthony Co. at Los Angeles.

Miller Heads Wolverine Laboratories—The Wolverine Laboratories has been formed to specialize in analysis of iron and steel, non-ferrous alloys, oils and coal. A fully equipped commercial laboratory has been opened at 445 Howard Street, Detroit, and is in charge of L. F. Miller, formerly chief chemist of the Timken-Detroit Axle Co.

Miller Goes West for Abbott—W. S. Miller, newly appointed representative of the Consolidated Car Company, maker of the Abbott-Detroit, has left for the Pacific Coast, as western manager for the firm. Mr. Miller's headquarters will be San Francisco. E. L. Sherwood, traveling representative of the firm, left on an extended trip to cover Southern territory.

Barber Stephens Six Sales Mgr.—A. C. Barber, for many years affiliated with the Moline Plow Co., trade department, has been appointed sales manager for the Stephens Six, the new car which is to be manufactured by the Moline company at the Freeport, Ill., plant. Mr. Barber will maintain offices in Moline and will make that city headquarters of the sales activities of the new motor branch.

Kesser Batavia Mgr.—Franklin Kesser has become Eastern district manager of the Batavia Rubber Co., New York City. Mr. Kesser was for ten years manager of the Hartford Rubber Works branch in Philadelphia, five years in an executive capacity at the Hartford factory, three years in executive positions with Akron tire companies, and for the past year jobbing representative of the Batavia Rubber Co. for the Philadelphia market.

Haas Monroe Sales Mgr.—L. D. Haas has been appointed sales manager of the Monroe Motor Co., Flint, Mich. He was formerly in a similar capacity with the Chevrolet Motor Co.

Schafer Joins Sterling Motor—A. E. Schafer, who was formerly vice-president and general sales manager of the Flint Varnish Works, Flint, Mich., and previous to that one of the directors and sales manager of the old Abbott-Detroit Motor Car Co., has joined the Sterling Motor Co., Detroit, Mich., in the capacity of general business manager.

Winnipeg Items—The business of the Russell Motor Co., Winnipeg, Man., has been transferred to the Western Canada Motor Car Co., and the cars manufactured by the Canadian-Overland Co. will be handled in Manitoba by this company.

S. Doupe, recently manager of the Winnipeg branch of the Russell Motor Car Co., has joined the staff of the Breen Motor Co.

The Alfred Maw Motor Co. has taken the Winnipeg and Manitoba agency for the Scripps-Booth.

The Johns-Manville Co. has opened a new accessory store on Portage Avenue West, Winnipeg, which is attracting a large volume of business.

Detroit King-Dort Co. Splits—A change in the distribution of the King and Dort cars in Detroit and part of the state has become effective today. The King Auto Sales Co. has been formed to handle the King and the George W. Franklin Co. will handle the Dort. Formerly both cars were handled by the King-Dort Sales Co., of which Mr. Franklin was general manager. The new King sales agency will have its quarters at 998 Woodward Avenue, where the King-Dort company was located. The Franklin company, which will distribute the Dort in Detroit and twenty counties of eastern Michigan, will locate at 698 Woodward Avenue.

Mountain Retail News—G. E. Turner, Fourteenth and Arapahoe Streets, Denver, has secured the Colorado distributing agency for the Smith Form-A Truck attachment for Fords.

H. I. Piatt, Grand Junction, Col., Saxon and Hupmobile agent, has sold out to go into another line of business in Michigan.

Miller & Smith, Grand Junction, Col., Ford service station proprietors, have bought H. I. Pitt's general garage business and moved their service station there.

The Fisk Rubber Co. has moved its Denver branch from 1635 Broadway into a new building at 1168 Broadway, constructed with large space for service use.

William Murr, Grand Junction, Col., has secured the agency for the Saxon, formerly handled by H. I. Piatt.

Boston Trade Notes—V. A. Charles, New England distributor of Inter-State cars, has placed a retail agency at Boston, with O. J. Vincent, formerly of the Chevrolet and Buick salesforces as manager. Salesrooms have been opened at 887 Boylston Street.

J. D. McIntyre, who was manager of the wholesale department of the Jackson Motor Car Co. of New England, for the past year, has gone into business for himself as distributor of the Denby trucks.

W. A. Frederick, who has been identified with motor and tire houses for some years, has been made assistant sales manager of the Batavia Rubber Co.

Iowa News Items—The Louis Otto Automobile Co., Davenport, Iowa, has closed the agency for the Moon car.

The Sieg Iron Co., Davenport, has put in a complete line of automobile accessories and garage equipment. A new addition to the plant houses the accessory department, which occupies 65,000 ft. of floor space.

Ohio Trade Items—J. H. Greenwald, Cleveland, Ohio, distributor of the Chalmers, has moved to a new location at 1900 East Nineteenth Street.

The Motor Equipment, Cleveland, has opened a store at 10202 Euclid Avenue, where a complete line of motor supplies will be carried. L. F. Mau is the manager.

W. A. Albaugh, Cleveland, has formed the Ohio Metz-Elcar Co., to act as distributor of the Elcar and Metz for the State of Ohio. He is president of the Albaugh Motor Sales Co.

The Perfection Spring Co., Cleveland, has purchased two more lots, making ten in all, to be used for the extension of its factory buildings on East Sixty-fifth Street, which is now under way.

C. C. Williams has been made sales manager of the Stark Auto Co., Cleveland, Ohio, distributor of the Allen car.

The Overland-Cleveland Co., Cleveland, Ohio, has taken over the ninety-nine-year lease on the buildings and grounds it occupies at 6604 Euclid Avenue. It has been decided to extend the building out to the Euclid Street line and make it three stories high, with an artistic front. At the rear the company will erect a building extending back to Carnegie Avenue, to be used as a service station. This will probably be five stories in height.

Wisconsin Trucks Being Delivered—The Myers Machine Co., Sheboygan, Wis., which took over the Wisconsin Motor Truck Co., Baraboo, Wis., early this year, is now making deliveries of its first products. A large addition which will be devoted to the motor truck works, is now being completed and will make it possible to attain a considerable production, but the company is hampered by the difficulty in getting materials. The Myers company is operating 24 hours a day and has orders ahead to make the extended schedule necessary for many months to come. The first truck, a 1-ton, was delivered to the Sheboygan Railway & Electric Co., and the second, a 3-ton, to the Konrad Schreier Brewing Co., Sheboygan. The trucks are known as the "Wisconsin."

Boston Trade News—The Fostoria Sales Co. of Massachusetts has been formed to handle that car in New England, with G. F. Lombard as manager. Salesrooms are located at 182 Columbus Avenue for the present.

The F. A. Dutton Co., agent for Abbott and Empire cars, has made Percy Reynolds manager of its sales force. He was formerly with the Bishop Motor Car Co., selling Premier and Westcott.

Sales Manager Hadley of the King Motor Car Co. has changed the branch at Boston into an agency. He has also placed an agency for the car at Providence with the Longley Motor Car Co., that has the Dort also.

Harry Fosdick of the Wentworth-Fosdick Co. has sold out his interest in the company to his partner.

W. F. Bennett, who owns the Union Square Garage, and the Ideal Supply Co., at Somerville, Mass., has taken the agency for United Trucks.

The name of the Porter Motor Sales Co., agent for the Pathfinder line, has been changed to the Cottrell Motor Co., after W. F. Cottrell, who has financed it.

The Monroe car is now represented in New England by the New England Whip Co. of Westfield, Mass., of which H. A. Cowles is the sales manager.

A. J. Wicks, former purchasing agent for the Cadillac company, of Boston, has become assistant manager of the Boice-Perrine Co., the big accessory house.

Standard Truck Buys Land—The Standard Motor Truck Co., Detroit, has purchased a tract of land 130 by 160 ft., on Bellevue Avenue, adjacent to the property purchased last year. This gives the company a frontage of 250 ft. on the avenue. A new plant is to be erected soon.

York Carbureter Corp. Formed—The incorporation of the York Carbureter Corp., Detroit, is announced, the capital stock being $60,000. The incorporators are Archibald and L. M. York and W. J. Tinney.

To Make Low-Priced Tractor—The Ohio Mfg. Co. of Upper Sandusky, Ohio, is testing out a new farm tractor in its plant. The tractor is designed to produce great efficiency, and sell cheap. It is expected that the tractor will be placed on the market in the near future.

Automobile Department Store in Peoria—The first automobile department store is to be erected at Peoria, Ill. The structure will be three stories, 150 by 200 ft., and will be located at 1701-7 Main Street. Everything pertaining to automobiles will be found in this building. It will be ready for occupancy Oct. 1.

New Co. for Davenport—The Central Auto & Tire Co., Inc., Davenport, Iowa, has recently been incorporated, with T. L. Kennedy, president and treasurer, and E. B. Kennedy, vice-president; O. R. Arnold, secretary and manager, and C. L. Cockfield, sales manager. Temporary quarters have been secured at 419 Brady Street. This company has secured the agency for the Fostoria light car and light deliveries, for four counties in Iowa and three counties in Illinois. It has also taken on the agency for the U. S. Motor Truck Co.

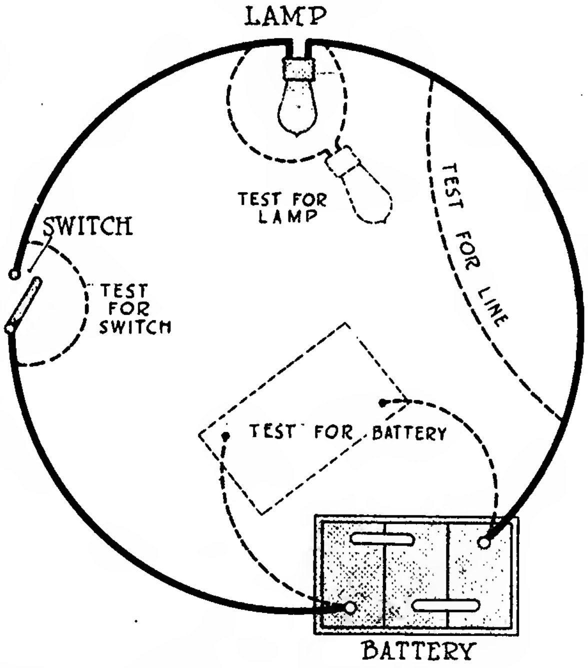
Automobile Electricity

Locating and Curing Troubles

PART I

The Electric Circle and Its Elements—Fundamental Principles of Tracing Faults—Knowledge Necessary Before Taking Steps to Cure Failures

By J. Edward Schipper



A fundamental electric circle or circuit and how it can be divided into arcs in finding trouble

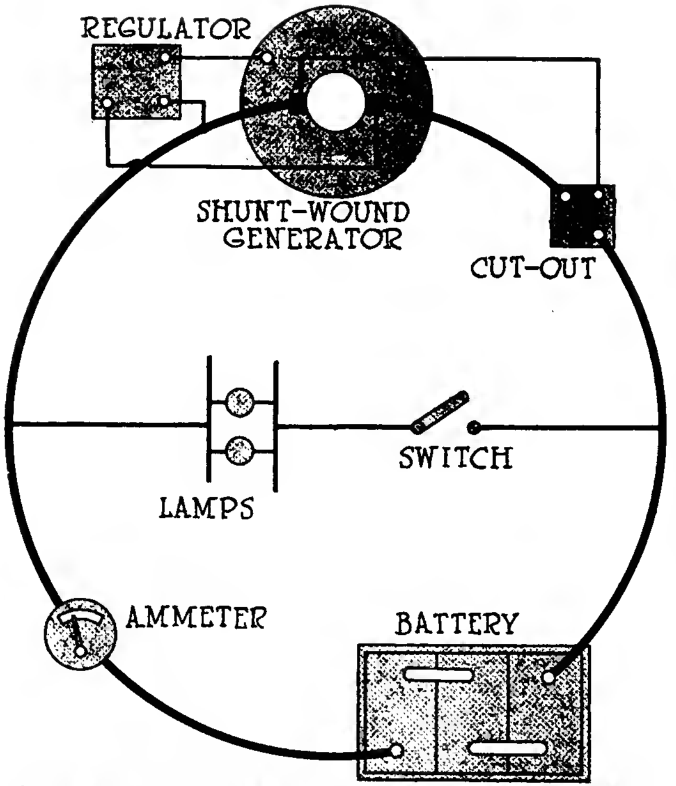
THE symbol of continuity is the circle. It begins at any point on its circumference and it ends where it begins. The flowing line which bounds the circle is complete and uninterrupted and must be so or it ceases to be a circle.

This symbol of continuity well expresses the characteristics of an electric circuit. The circle must be complete, for if it is interrupted current ceases to flow in just the same way as the circle ceases to exist as soon as the peripheral line is broken. This picture must be in the mind of anybody thinking of an electric current. He must visualize the complete circle of flow which begins and ends at the same point, or it may even be said which has no beginning and no ending. It is a continuous flow of energy harnessed to do the desired tasks by devices incorporated in the circular chain. No matter how many of these devices there may be or through how many phases of activity the circle of energy may pass, it must necessarily be complete. The electric current and the circle are synonymous.

This series of articles has to do with troubles in automobile electrical systems. These troubles are expressed and are shown by interruptions in the electric circle, call it circuit if you so desire, of which they form a part.

When a civil engineer has a surveying problem to meet he generally solves it by getting at it on three sides. It is possible to take a leaf from his book and use the same method by taking three different viewpoints from which to gain an insight into the finding and remedying of troubles on lighting and starting systems. These three viewpoints are: First, a grasp of the electric circle or circuit, as it is known in technical parlance; second, a method by symptoms in which the interpretation of visible effects of electrical irregularities is given; third, a viewpoint by units in which each individual part of the complete lighting and starting system is taken up separately and the vulnerable points indicated.

In other words to get a true perspective of the entire electrical layout on the car these three fundamental methods of approach must be consciously or unconsciously followed in order that a logical order is maintained and the process of elimination which was pointed out as the true method of search, carried to its conclusion. The broad idea of electrical flow must be first in mind; second, the symptoms which lend a



The lighting circle—Here the principal units consist of the generator, regulator, cutout, battery and ammeter on the great circle and the lamps and switch on the inner arc

helping hand in reducing the necessary area of search and third, a knowledge of the functions of each part in the system and the points at which troubles may occur.

Must Visualize the Circle

To think electrically the mind must travel in a circle. No matter at what point you start, you must travel around the circle and back to that point before you have completely covered the system or part of the system which you are studying. All through the electrical equipment of an automobile, no matter what part is taken, the mind's eye must visualize that complete circle. No electricity will flow unless the circle is complete and as soon as the circle is complete, whether it is completed wittingly or not the current will flow through the circuit.

On the car there are three great electrical circles to bear in mind. These are lighting, starting and ignition circles. In connection with these systems there may be smaller subcircles, but these are all included in these three major circuits. If the mind can visualize each of these and picture it applied practically to the car, the first great step in becoming capable of handling electrical troubles will have been accomplished.

The elementary principle is the same no matter if the circle under consideration contains the most delicate electrical apparatus. If the circle is made up of a battery, a lamp and a switch it is complete and the other additions only widen the circle without altering any of the fundamentals.

The illustration on the first page brings this out clearly. It shows the circle of flow and also shows how piece by piece this circle can be gone over to locate the trouble. If the circle were broken at any point the current could not flow. It is the function of the switch to make and break this circle and by it the electrical circuit is completed or not according to whether the operator wishes the lamp to be out or lit. This circle idea should be borne in mind when studying the laws of current flow.

First Principles of Electricity

No one knows what electricity is, but many of its qualities are so well known that they can be utilized. The laws of current flow, the methods of generation and the manifestations of electrical energy are the three main points which must be grasped before any conception can be had of the main and sub-circles of electrical flow as manifested in starting, lighting and ignition circuits.

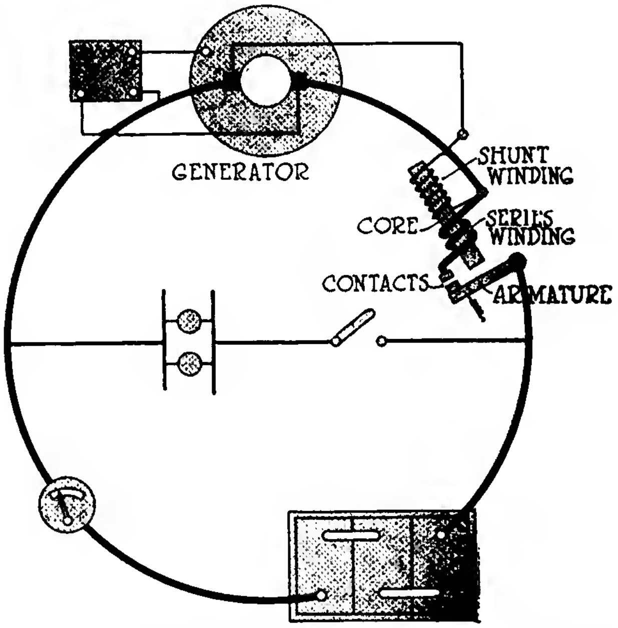
In order to make current flow through an electric circle two conditions are necessary: first, that there is sufficient pressure to force a flow of current around the circle through all the resistances of the line, and secondly, that nowhere on the line is there sufficient resistance to prevent flow. On analysis these two conditions really mean the same thing, that is, that a path is finished for the current and that there is sufficient voltage or pressure to force the current over that path.

Basic Testing Method Explained

This fundamental condition for current flow gives a basic scheme for testing electric circuits. Knowing the cycle of events it is only necessary to apply the process of elimination and to go step by step taking a definite arc of this circle at a time until finally the whole circle has been covered and the weak spot located.

Referring to the simple electrical circle which is described as a battery, switch and lamp with connecting wires, it is possible to see how this simple circle can be divided into a number of smaller arcs when testing for some trouble which causes a total or partial interruption of the current flow. In the first place to know that there was some trouble we would have to have symptoms. These might be shown in a continual leakage of the current from the battery when the switch is not on or they might be shown in a failure of the lamp to light brightly or at all when the switch is turned on. Either of the conditions outlined denotes trouble, and when we set about finding the cause of the trouble we must do so by the process of elimination. Let us say that the lamp does not light when the switch is turned off. Immediately the mind must picture an interruption in the complete circle of current flow from battery to switch, from switch to lamp, from lamp back to battery. This is the external part of the circle and the final connecting link is the internal current from the negative pole to the positive pole within the battery.

One by one we must bridge across these definite arcs of the complete circle to locate the source of trouble. Starting with the most obvious, the lamp, with the switch turned on, we might see if the lamp is tight in its socket. If it is loose

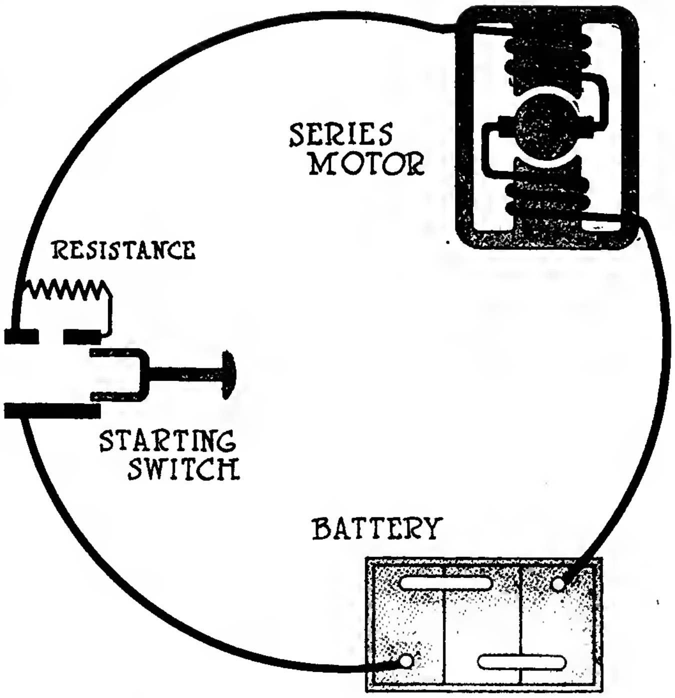


How the circle passes through the cutout unit showing the sub circles which are involved in this particular phase of proper lighting arrangements. The shunt winding is the sub circle while the series winding is a direct part of the main circle the circle is interrupted here. Next it might be found that the lamp is burnt out. This can be determined by examination of the lamp filament by eye or by the substitution of a known perfect lamp. Then the connections of the wire at the lamp are examined. If these things are all found to be perfect we move to the next point in the circle, the switch. Bridging across the terminals of the switch by another wire cuts off this part of the arc and tells us at once whether or not the trouble is at the switch. Should the lamp light when the switch is bridged it indicates a faulty switch. If bridging the switch indicates no trouble here the next move is to the battery and this part of the arc can be bridged by trying a known perfect battery or by using an electrical measuring instrument on the battery to see if the electrical pressure or voltage of the battery is sufficient to send the current over the line and to light the lamp. Should this test fail there remains going over the wire piece by piece to see that there is no break.

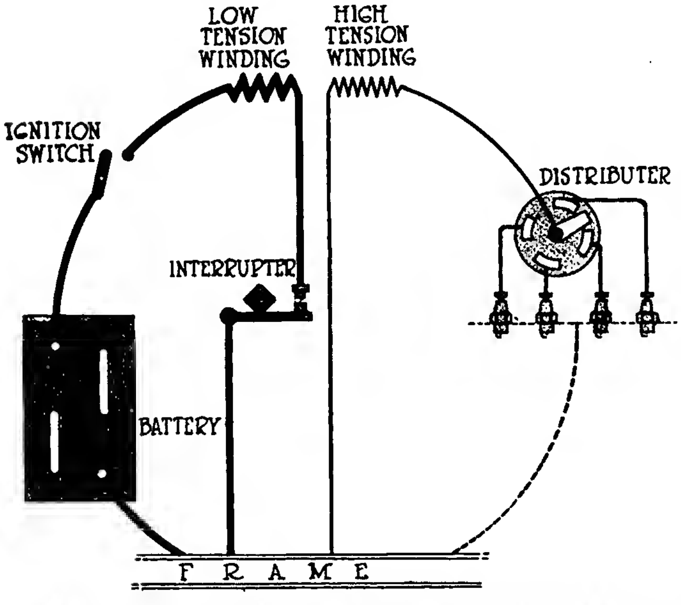
Elementary Principle Applies

In doing this work the most elementary stage of electrical trouble-finding has been accomplished. No matter how complicated the circle may be this original principle applies. The elementary methods may have to give way to more complex systems of testing on complicated electrical installations but nevertheless, the basic scheme must remain. Searching must be done by a process of elimination by gradually working through the entire circle. Of course certain obvious troubles will render unnecessary the complete search, but as soon as this occurs the trouble ceases to be electrical and requires mechanical treatment suggested by the damage. Speaking exactly, there is no such thing as electrical trouble. The imperfection is due to an interruption in the functioning of the electrical units caused by some mechanical fault. Machinery and mechanism may fail but electricity, that hidden form of energy of which no one knows the exact definition, will never fail provided the mechanical paths or circles are kept intact to allow it to perform its work.

Having grasped the elementary law of electrical current flow and the fundamental principle of searching for interruptions in electrical apparatus, the next step is to see how these rules are applied to the great circles of automobile electrical mechanism. Starting, lighting and ignition are these three circles. They can be taken independently, for although on many installations units of one will be units also of the other, still in each case the complete circle exists.



A simple circle is that of the starting motor. Here the current flows from battery to switch, then to the motor and back to the battery again. Often times there is a sub circle for the starting pinion engagement when this is accomplished magnetically



The ignition circle is made up of two parts, low tension and high tension. Nevertheless, the complete circuit idea is clearly shown as each part must be complete before the functions are correct

Simplest of all is the starting circle. Current flows from the positive side of the battery, through the wire to the motor terminal, then through the field winding passing on to the armature winding, then to the switch and back to the negative side of the battery completing the circle.

Study of the Starting Circle

Another part of this article will be devoted to symptoms of trouble. Let it be assumed that it is known that trouble lies in the starting circle. The question becomes how is it possible to apply the basic principle of testing to this more complicated circle? It can be done readily simply by following out the system of process of elimination which has already been stated to be the universal method in finding trouble.

Let the arcs into which the circle is divided be: First, the battery; second, the starting switch; third, the starting motor and fourth, the wires and connections. Let us take for our means of testing a simple test lamp consisting of an ordinary 6-volt bulb with a couple of leads, assuming this system to be a simple 6-volt arrangement. The first arc we have taken is the battery. Placing the ends of the testing lamp wire across the positive and negative poles if the lamp burns brightly it is quite evident that the battery is giving its 6 volts pressure. Remove the negative wire from the battery and put one of the test lamp terminals in contact with the negative pole of the battery and the other terminal of the lamp in contact with the end of the detached negative wire. If there is a short circuit in the system the lamp will light. In case it is a single-wire system instead of touching the terminal of the test lamp to the negative wire it will go to the car frame instead, and hereinafter when the negative wire is spoken of it will mean the car frame on single wire or grounded return systems.

The next arc of the starting circle is the switch. It is not always possible to simply bridge across the switch with a heavy piece of cable because the switch generally incorporates a number of features for the engagement of the pinion of the starting motor, etc. Therefore, it will probably be necessary to take the cover from the switch and examine it carefully, tracing the wiring and seeing that none of the parts are fused or burnt away and that all connections are firm and solid. If the switch is of the two-point type in which the first point of engagement causes the current to flow through a resistance allowing the starting motor to turn slowly while the pinion engages with the flywheel it will be possible to bridge first across the resistance and then across the entire switch. If the motor runs properly and cranks the gasoline engine when this is done the trouble is in the switch and this can be taken off and examined and the trouble corrected. If the starting switch blades do not make contact or the switch terminals are loose this can generally be found from inspection. A grounded or short-circuited starting switch will often be not so easy to locate and the insulation of this part of the circuit should be gone into very carefully before passing on to the next part of the arc.

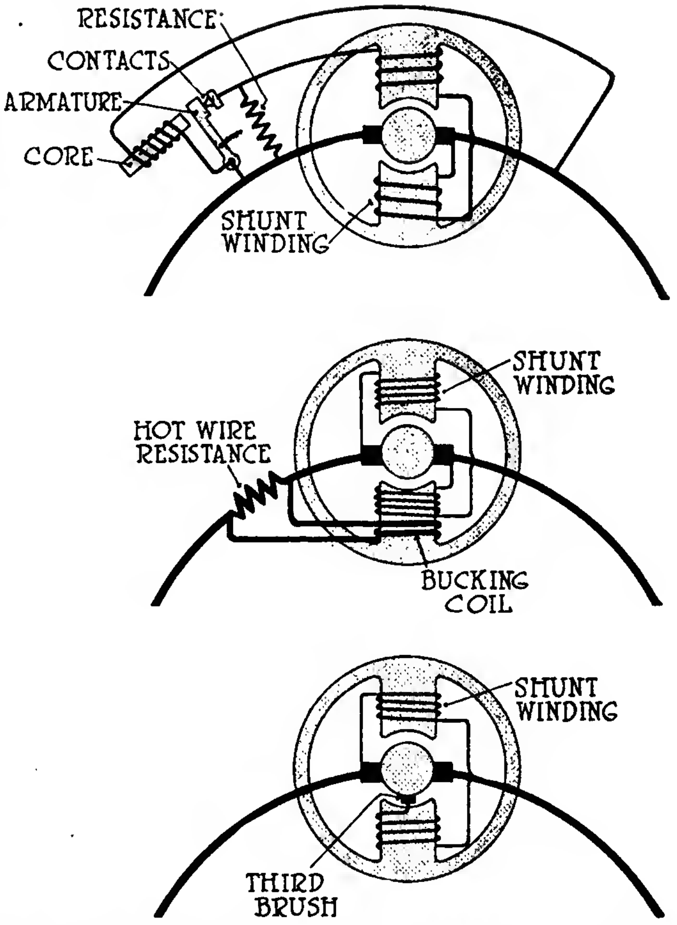
Checking the Starting Motor

After examining all the wiring and connections in the starting circle, it is necessary to come finally to the starting motor itself. The course of the windings through these motors is always the same since they are all series-wound. Current passes from the battery to one of the terminals of the motor which is connected with the winding around the magnetic field. The current passes through this field winding and thence to the commutator of the motor where it is led to the armature winding. The current passes through the armature from one brush to the other and thence back to the battery. There are only certain parts of the starting motor that are susceptible to repairs by any except the factory. The armature is rendered practically impregnable in the insulation process and cannot be generally torn down and rewound. The same applies to the field windings. The commutator, brushes, brush holders, external leads, brush pigtails as the wires to the brushes are called, and other external parts which are accessible by removing the commutator housing are generally susceptible to repair by people with a limited amount of electrical equipment or skill.

The lighting circuit is made up of two circles, one bounded by the battery lamps and control switches with the connecting wires and the other from the generator to the battery including the cutout relay mechanism, the fuse connections and the regulator.

Circle Not Always Plain

The battery lamp circuit on the whole is about the simplest electrical circle on the car. Leaving the positive terminal of the battery the current passes through an ammeter, then to the lighting switch from where wires lead to all the lamps and back to the negative side of the battery. Regardless of how the lamps are connected, whether in series or parallel, each one is a simple part of this circle. Should one lamp go out and the others act perfectly local troubles are certain to be the cause. If the circle is broken as a whole all the lights will go out and it then becomes a matter of searching for the break. Piece by piece this circle can be divided into small arcs and one by one they can be searched for the trouble. It is almost a parallel with the elementary battery switch and lamp circle first described except that here we have an ammeter and several lamps in addition. The battery can be tested with the test lamp across the terminals. The ammeter can be tested by bridging around it with a connecting wire. The switch can also be bridged as can the main leaves to the lamps and the connections to battery and other terminals. Once the trouble is located in such a definite locality as the switch, ammeter or terminal connection it can be definitely determined and the suggested remedy applied. While the battery lamp circle in itself is simple it will be oftentimes puzzling or even impossible for the layman to visualize this circle actually on the car. Some of the wiring systems carry the wires of this circle through such a course that it would be impossible to follow it and therefore it is necessary for the person working with any car to have a knowledge of its wiring diagram. This should be secured before experimenting with the wires.



The regulator sub circle varies in its arrangement. Here are three typical regulation methods, top the vibrator type; center, hot wire resistance; bottom, the third brush method

An instance of this is in a given two-wire system where the battery lamp circuit takes the following course. The positive battery lead runs directly to the starting motor field. From this lead is led the wire to the ammeter. Leaving the ammeter the course of the current is then through the lamps, then through the lighting switches passing through the series field winding of the armature and back to the motor starting switch where contact is made with the negative lead of the battery completing the circuit. This does not sound like the simple battery lamp circle and yet in effect that is all it amounts to.

The other lighting circle includes the generator. It also includes the delicate and ingenious schemes of regulation and contact breaking. Starting on the positive brush of the generator the current flows through the contact breaker and then to the positive lead of the battery. Passing through the battery the course of the current is then through the ammeter and back again to the generator. In the path of this current somewhere in the circle is inserted the regulating means. The position of this depends on the method chosen. Another circle within this greater circle is the means for exciting the generator field. Regardless of what method of regulation and what method of field excitation is used the law of continuity as expressed by the circle exists, and this circle also can be divided into smaller arcs in tracing down the troubles which are apt to occur.

Having incorporated in this circle an ammeter a great amount of assistance is given in determining where to look for the trouble. The ammeter indicates at once if current is flowing from the battery and should this be so with the switches off it immediately suggests a short or ground. Taking up the step by step bridging process a start is made as usual from the battery. The test lamp will show if this is in proper condition to light the lamps. An examination of the terminal connection will show if these are tight. If there is a breakdown in the ammeter, wire can be bridged around it immediately indicating if this is true. Coming to the generator it is a matter of going step by step over the commutator, brushes, brush holders, springs, brush connections or pigtails. Mechanical troubles of course will enter into the reckoning and a seized armature or worn or broken down armature shaft bearings must be looked for. There is very little that can be said about the wiring of the generator as when the winding is impregnated with insulating compound and baked it becomes as hard as a mass of rock. Coming to the contact breaker this can be bridged across and if generator does not charge as indicated on the ammeter it is possible to connect around the circuit breaker momentarily to see if there is a failure of operation here. The connection around the circuit breaker need not be an actual wire connection but generally only amounts to pressing the contact points together with the finger and observing if the ammeter indicates charge when the engine is running at a speed above the charging rate. Theoretically it is the same as the basic principle of testing as first laid down with the battery switch and lamp.

The ignition circuit can be tested by applying the same principle. It is only a matter of systematic step-by-step trying in using the process of elimination to get to the source of trouble. This series deals with starting and lighting but the elementary principles it brings up are applicable to all electric circuits.

Trouble Hunting Notes

In testing the battery it is well to determine if the troubles are distributed throughout the entire battery or confined to one or more cells. The bridging method of testing can be applied to the battery in order to determine this. A small voltmeter is handy as this can be placed across each cell to indicate if it is giving the 2 volts pressure that is required. One of the first places to look for trouble is in the battery electrolyte. This should be kept up to the proper level by adding distilled water frequently so that the plates are covered. The battery in which the plates are not fully covered by the electrolyte has a decreased capacity due to the fact that the active material in the upper parts of the plates becomes hardened and unfit for use. Another point to observe is the specific gravity of the electrolyte which should be between 1.275 and 1.300 when the battery is fully charged. A battery should never be discharged lower than 1.150. The instrument for making these tests is the hydrometer or hydrometer syringe which is especially adapted for storage battery testing. Keeping the electrolyte in proper condition is about all the car owner can do beyond keeping the battery clean without acid on the outside as more complicated repairs require equipment which is only in the hands of battery manufacturers.

When troubles occur, before more serious or complicated parts are disassembled examine the wiring. Two things are necessary in going over the wiring of the car. First a knowledge of the wiring diagram, and second, the application of the elementary testing principle of bridging the trouble. There is always the possibility that in the original wiring of the car an error has been made and therefore when the circumstances seem baffling it is wise to check the wiring of the car against the wiring diagram. The electric circle must always be complete and loose connections or short circuits which interrupt it must be found by going over the wire step by step.

Improper adjustment of the regulator is an example of an electrical trouble which will not be found by the primary bridging method. It is to locate such irregularities as these that the ammeter is placed on the car, or if an ammeter is not used some form of current indicator with the words Charge and Discharge in place of the indicating needle. The driver should know at what speed the battery becomes connected to the generator by the cut-in mechanism and if this does not occur until the speed is too high the battery will not receive sufficient charge in many instances to carry the lamp and starting load as it should. In many instances not every repairman is authorized to adjust the regulator and for this reason it is necessary to take the car to the service station of the starting and lighting company that has made the installation.

Some Extraordinary Conditions

There are other troubles which will not be located by the ordinary bridging method and these are particularly in and around the commutator assemblies. All generators and motors, however, are arranged to have the commutators accessible by the removal of a cover plate and all that is necessary in searching for trouble here is to know the mechanical conditions which should obtain. These are namely, a clean commutator with the mica between the segments undercut so as not to interfere with the contact of the brushes, a good brush contact given by proper spring pressure by a proper fit of the brush in its holder and by a proper engaging surface of the brush and perfect pigtail or brush wire connections. All of these can be determined by inspection.

One word of caution which cannot be expressed too strongly is not to be satisfied after having found the actual manifestation of the trouble because this may be the effect and not the cause. Until the cause is removed the effect will be bound to recur with the annoyance of having an interruption of service and a consequent expense and loss of time.

To put this in another way the circumstances which are causing the trouble may not be in the place where the manifestations of trouble are noted. One or two examples to illustrate this point will give a clear view of what is meant. A man drives his car into the repair shop with a stripped ring gear on his flywheel. Evidently nothing else is wrong. The repairman simply performing the obvious renews the ring gear, the car starts satisfactorily and the owner drives away. In a few days he returns with another stripped gear. The point is that when the repairman renewed the gear he only remedied the effects of the trouble but did not cure the cause, which was in a faulty starting switch which did not always make contact with the resistance circuit giving a slow movement of the armature of the starting motor before it went into full engagement and secured the full torque of the starting motor.

Examine Entire Circuit

No one would say that when a fuse blows or melts that the trouble is in the fuse. Before replacing the fuse it is well to look for the trouble on the circuit in which the fuse is connected. The test lamp can be employed to great advantage in doing this. For instance, if the blown fuse is in one of the lamp circuits the lighting switch can be turned so that all the lamps should light. The test lamp terminals should be put on each of the fuse clips and if the lamp lights the ground trouble is still there. Connect the test lamp to the negative wire of the battery and then with the other side go over it piece by piece until the lighting lamp indicates the position of the ground or at least what parts of the circuit are grounded. In each step that is taken remember the electric circle and bridge it arc by arc until the whole system has been covered.

Cheapening Cars by Reducing Varieties

A Scheme for Cutting Cost by Establishing Standard Engine Dimensions, Etc.—A Speculation of Standardization's Possibilities

By William Kent

IN The Automobile for Dec. 30, 1915, appeared a complete list of specifications of the 1916 cars, with their sizes and prices. They are divisible into four classes, viz.: two-, three- and four-passenger, five-passenger, seven-passenger and closed cars. The list shows a most confusing variety in size of cylinder, length of wheelbase and price.

During the experimental stage of the automobile industry such a variety was to be expected, for designers had no precedents to guide them, and it was necessary to try out a great number of proportions before standards could be determined upon. The time has now arrived, however, when the multiplicity of sizes and proportions can be considered only as a great economic waste, causing unnecessary duplication of the work of designers, draftsmen and pattern makers, and in the case of all except the largest manufacturers, a high manufacturing cost.

From the lists given, I have selected the list of the five-passenger cars as an example, and have subdivided it into four-, six-, eight- and twelve-cylinder cars, as in the accompanying Table 1. The table shows that on the average the price of a car bears some relation to the size, but individual cars of one size show extraordinary variations in price. Thus, of four-cylinder 22.5-hp. cars, the range of prices is from $440 to $2,700, and of six-cylinder 38.4-hp. cars the range is from $1,095 to $4,300. Of course, the size of an automobile is only one of the factors in its prime cost. Other important factors are quality of material, workmanship, finish, upholstering, size of tires and miscellaneous accessory equipment. The prime, or factory cost also is only one of the factors of the selling price, the margin between the two depending on the selling policy, the cost of making sales, including in many cases expensive advertising, the commissions or profits of dealers, and the manufacturer's profit per car.

High Price Causes High Cost

As a general rule, a high selling price is a cause of high factory cost, for it limits the volume of business and thus increases the overhead factory expense per car, which decreases as the volume of business increases.

Table 1 shows that seventy-seven makers are producing 103 styles of five-passenger cars, ranging from 13.2 to 60 hp. and 100 to 147-in. wheelbase, and priced from $440 to $5,900. As regards size, it would seem reasonable that ten or twelve different sizes would cover all the possible needs of the users of the cars, but the manufacturers are furnishing no less than forty-five different proportions of cylinders, including twenty different diameters from 2⅝ to 5⅛ in. and fourteen lengths of stroke from 3½ to 7 in.; thirty-three different horsepowers from 13.2 to 60, and twenty-eight different lengths of wheelbase from 100 to 147 in.

Table 2 is an attempt to show the relation of the selling price to the size of a car, arbitrarily taking the "size" as the sum of the horsepower and the wheelbase. By dividing the total range of this so-called size, from 115 to 207, into seven classes, and taking the average price for each class—after omitting from one to three cars in each class which appear to have fancy prices—we discover that, with the exception of the ten smaller and the four larger cars, the average price varies approximately as the cube of the size. The formula representing the relation of price to size is

$$\text{Price} = [0.01\ (\text{hp.} + \text{w.b.})]^3 \times C.$$

For eighty out of 102 cars averaged the value of C ranges from 354 to

429, generally increasing as the size increases.

For the ten small cars the average value of C is only 338, and for the four large cars it rises suddenly to 702.

If there were a uniform demand for all sizes of cars it would reasonably be expected that the factory cost of cars would vary, not as the cube of the size, but approximately as the square; but the fact is that there is an enormous demand for small cars, which tends to reduce both the factory cost and the cost of selling these cars, and a small demand for the large cars which increases their factory cost and greatly increases the cost of selling them. Hence the result that the price of the large car increases more rapidly than the cube of the size does not seem to be unreasonable.

Taking the Ford car, the smallest and also the lowest priced car on the list and the one for which there is the greatest demand, and applying the formula to it, we find the value of C is only 242. The low price of this car, together with its excellent quality, causes the great demand for it, reduces the expense of selling it, warrants the investment of a great amount of capital in its manufacture and the use of the best machinery in making it, making possible the smallest labor cost together with the highest wages to workmen, and produces the largest annual profit.

One of the causes which makes it possible to sell the Ford car at its low price is the fact that only one size of car is made. If the Ford factory, with its present size and its present capital, should undertake to make half a dozen different sizes of car, ranging from 22 to 60 hp., it is safe to say that the profits of the business would be greatly reduced, and that the factory cost of the present car would be increased. But if Mr. Ford or a combination of makers should with increased capital undertake to meet the demand for different sized cars from 22 to 60 hp., it is certain that not more than six or eight different sizes of cylinders would be selected within that range, instead of the forty-five different sizes that are now made by the seventy-seven makers.

Of the forty-three six-cylinder cars in Table 1, thirty are found with only six diameters of cylinder, viz.: ten 3 by 5, 21.6 hp.; five 3¼ by 4½, 25.3 hp.; six 3½ by 5 to 5¼, 29.4 hp.; three 3¾ by 5 to 5½, 33.7 hp.; and six 4 by 4½ to 6, 38.4 hp., while the other thirteen are all of different sizes, including seven different diameters of cylinder. If the makers of say ten out of these thirteen cars were to abandon their present exceptional sizes of cylinder and adopt one or other of the five sizes of the thirty cars, it would be possible for numerous economies in factory costs to be effected and considerable reduction in selling price to be made, with consequent increase of business and annual profits.. With standardization of sizes of cylinders would come standardization of pistons, piston rings, connecting-rods, crankshafts and their bearings, springs and other parts of the machine.

Possible Standard Sizes

Table 3 is a tentative list of standard sizes, thirteen in all, with five diameters of cylinders. The average price is figured from the formula, with the values of C for different sizes taken approximately as those given in Table 2, rejecting those of extreme price. Figures are

102				

Ford car, 3¾ by 4 in., four-cylinder, 22.5 hp., wheelbase 100 in. $\left(\frac{\text{HP.} + \text{W.B.}}{100}\right)^3 = 1.84$. Factor for price $\frac{440}{1.84} = 240$, or 28 per cent below the average factor for ten small sized cars given in the table.

also given for low-priced cars 30 per cent below average, and for high-priced cars 30 per cent above average. Low price and high price have no necessary relation to either the quality of the car or to the profit per car, to either the manufacturer or the dealer. If the price of a certain car is $1,000, cutting its price to $700 may increase its sales so that $100 per car may be saved in selling expense, $100 in factory cost and $100 per car taken from manufacturers' profits without reducing the annual profits of either the manufacturer or dealer.

A similar car may sell for $1,300, with a reduction in the number of sales, an increase of $100 in the selling cost, $100 in factory cost and $100 in manufacturers' profit per car, but with no increase in annual profits. The difference between the low-priced car and the high-priced car is $600, but the high-priced car may not be any more profitable as regards annual profits than the low-priced car.

The great reduction in selling prices of automobiles during the last two years has surely not yet reached its limit.

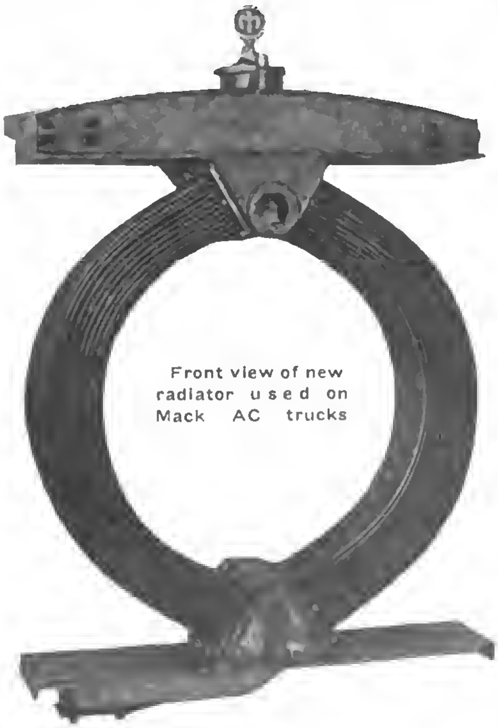
Solderless Radiator Used in Mack AC Trucks

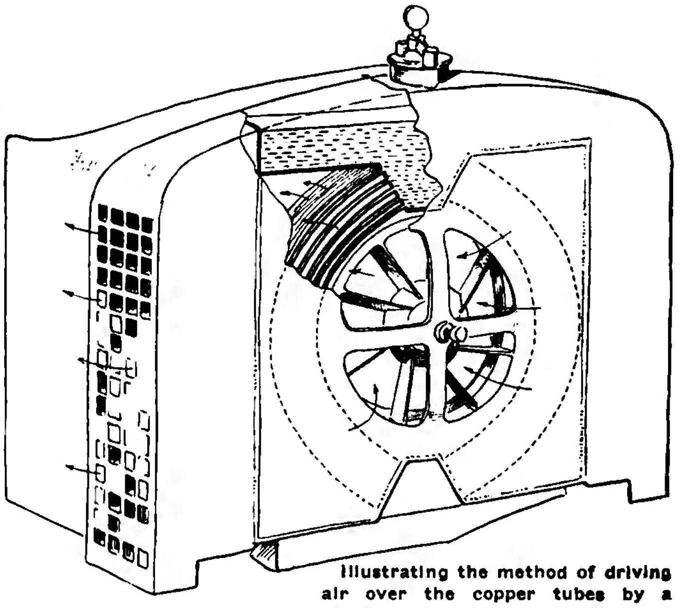
THE radiator used on the Mack model AC trucks is a new design. By the use of a large number of practically semicircular sections of copper tubes, which are expanded into plates that in turn are bolted to top and bottom headers, a solderless radiator is obtained, which expands within itself and withstands severe vibration without failure.

Both top and bottom headers are of aluminum alloy and the upper header forms part of the cowl, while the lower is part of the frame that supports the radiator. The tubes are expanded into the end plates and no solder is used in the construction. As each tube is a unit in itself, one or more of the tubes can be blocked or pinched off in case of emergency without interfering with the others.



Front view of new radiator used on Mack AC trucks

Instead of being placed in front of the engine the new radiator is installed back of it, and a centrally located fan draws air from the driver's cab as well as the motor compartment, and discharges it at the sides. Thus a constant stream of cool air is passed over the radiator tubes, and, as screens are provided on each side of the hood, cool air is also drawn past the engine.



Illustrating the method of driving air over the copper tubes by a radial fan. Arrows show air currents

Freezing Leaves Tubes Uninjured

An illustration of the way tubes of this radiator will stand expansion and contraction without leakage is shown in the case of an AC truck that was left standing outdoors on a very cold day. The water in the radiator was frozen solid, and so great was the strain upon thawing that the lower section of the bottom header burst, yet the tubes remained in perfect condition. Replacing the broken header was an easy matter. The bolts were removed from the two plates holding the tubes, after which the header was unbolted from the chassis and a new one bolted in its place.

Testing Aeroplane Motors with a Fan Dynamometer

When Testing Air-Cooled Types Allowance Must Be Made for Temperature of Air in Which Blades Rotate—If Apparatus Is Correctly Designed and Installed Results Should Be Accurate

By Lawrence Hodgson, B. Sc., A. M. Inst. C. E.

From a Paper Presented Before the Institution of Automobile Engineers

DURING the past year the author wished to use the fan brake dynamometer for accurately determining the horse-power developed by aviation engines. He had available an apparatus which he had designed for testing small propellers in water, and he decided to use this apparatus in order to obtain a better general view of the laws of resistance of fan brakes than could be obtained from the paper above referred to. All tests were carried out with the fan rotating in water, with the exception of one check test (marked A, Fig. 1) which was taken with the fan rotating in air.

In the water tests, the vertical spindle carrying the fan was rotated in a covered tank of still water, 20 ft. square and 5 ft. deep. The blades used were ½ in., 1 in., and 2 in. square, and ½ in., 1 in., and 2 in. in diameter. They were cut from smooth German silver sheet 0.012 in. thick, and the edges were left sharp and at 90 degrees to the face of the blades. The fan spindle was driven by a small air turbine attached directly to it, and the driving torque measured by means of a manometer which indicated the pressure at the turbine jet. The relation between the driving torque and the readings of the manometer was determined by a series of brake tests taken at various jet pressures and turbine speeds. The plane of the fan arms was 10 in. below the surface of the water, the coefficient of resistance having been found to be constant for the largest diameter of fan used for all depths of immersion greater than 6 in. The apparatus and the observer were carried on a platform which bridged the tank. In every case, before a reading of the speed of rotation was taken, the fan was rotated under constant torque until there was no further increase in the speed. The speed of rotation was measured by timing the revolutions of a slow-moving wheel geared to the fan spindle. The temperature of the water during the experiments was approximately 50° F.

Analyzing the Tests

In analysing the results, it was assumed that for geometrically similar fans, the resisting torque due to the blades alone varied as the fifth power of the linear dimensions, as the square of the revolutions, and as the density of the fluid in which the fan rotated. It was further assumed that the coefficient of resistance, κ, would be different for fans which were not geometrically similar. For the square and round-bladed fans which the author used in his experiments, the proportions of the fan were specified by the ratio r/s, and the values of κ in the equation

$$\mu_b = \kappa N^2 r^3 s^2 W \quad \dots\dots\dots\dots\dots\dots (1)$$

were therefore determined for various values of this ratio for each shape of blade. A separate series of tests established the fact that the torque due to the arms alone (μ_a) was given with sufficient accuracy by the formula

$$\mu_a = 0.35 \times 10^{-8} \sigma N^2 r_a^4 t W \quad \dots\dots\dots\dots (2)$$

In order to increase the accuracy of the measurement of the torque due to the blades alone, when r/s was large, μ_a was made as small as possible by using arms of steam-line form. The outside radius, r, was used in Equation (1) in preference to any other linear dimension which varied with the diameter of the fan, such as the radius of the centre of pressure or of the centre of gravity of the blades, because it was the linear dimension most easily measured.

Fig. 1 shows the values of κ for square and circular blades plotted against the ratio r/s, as determined from the author's experimental results. It will be seen that κ varies very considerably with r/s, when r/s is small, but approaches a constant value when r/s is large; further, that this constant value of κ for the circular blades is about 0.7854 times less than for the square blades.

Fig. 2 shows the author's values of κ for square blades, compared with the values deduced from Messrs. Morgan and Wood's tests when analysed on the basis of Formulæ 1—5. It will be observed that Messrs. Morgan and Wood give no tests on fans for which r/s is greater than 2.5. The point marked P in Fig. 2 corresponds to the value of the constant in Mr. Poppe's formula, Mr. Poppe's tests being made on fans for which the values of r/s varied from about 2.5 to 10.

It will be seen that there is a close agreement between the author's values of κ and those deduced from Messrs. Morgan and Wood's tests. This agreement is all the more remarkable when it is remembered that the author's experiments were made with small blades in water, and using a motor of less than one-thousandth of one horse-power. Such close agreement between tests taken in media of widely different densities appeared to indicate the probability of some error in Messrs. Morgan and Wood's observations on the barometer and temperature effects.

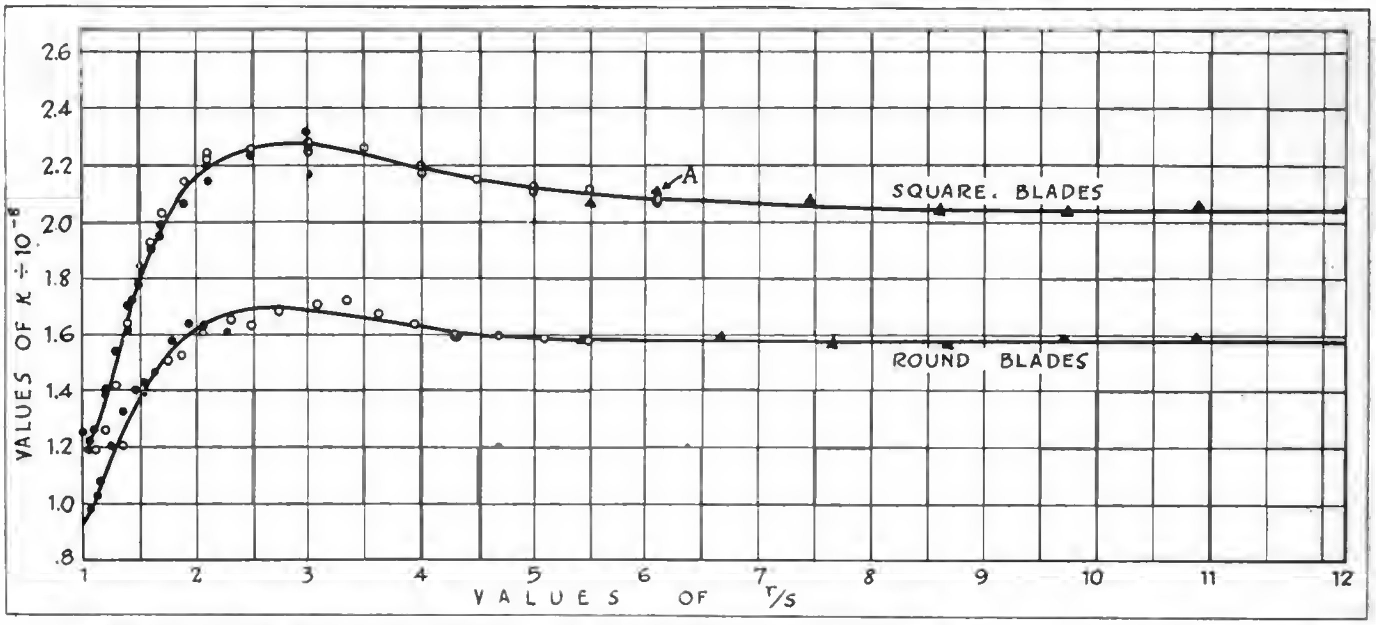
In order to investigate this point further, the author carried out a series of tests on a fan rotated in air under constant torque in a closed chamber. The density of the air in this chamber was changed by small steps from 0.076 to 0.540 lb. per cubic foot by increasing the pressure, and from 0.076 to 0.600 by increasing the temperature.

Over the whole of this range, the relation

$$N^2 W = \text{constant}$$

was found to hold. The check point, marked A in Fig. 1, which was taken with the fan rotating in air, further confirms the conclusion that the resistance to rotation varies directly as the density of the fluid in which the fan rotates.

When testing air-cooled aviation engines an error may be introduced if the temperature of the air in which the blades rotate is not allowed for. This temperature may be obtained by means of a small alcohol thermometer, some 2½ in. long encased in a perforated brass tube, and reading between 60° F. and 120° F., attached to the blades or the extremity of the fan arms. The thermometer should be fixed with its



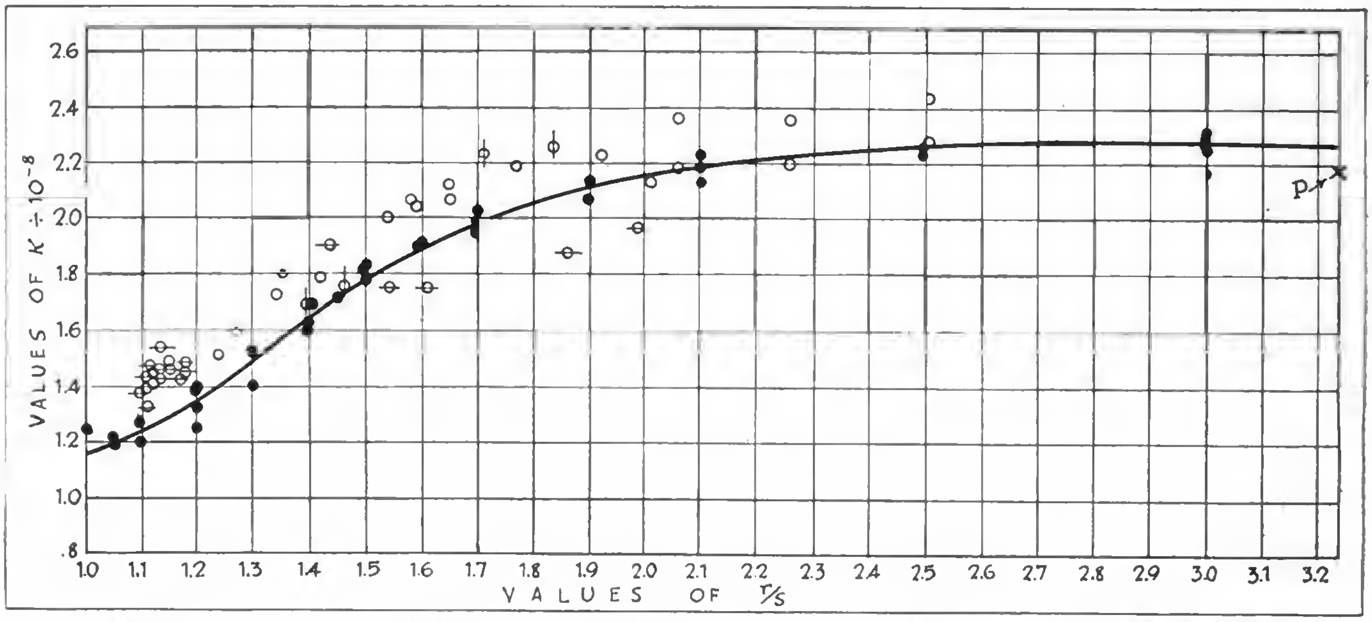


Fig. 1—Above—Curve showing the values of K for square and circular blades plotted against the ratio r/s, as determined from the author's experimental results. Fig. 2—Below—Curve showing the author's values of K for square blades, compared with the values deduced from Messrs. Morgan and Wood's tests when analyzed on the basis of Formulae 1-5

stem radial, so that it does not appreciably interfere with the stream-line flow past the arms and blades. Or, alternatively, the thermometer may be clamped to a pillar resting on the ground, so that its bulb is in the same plane as the fan arms and an inch or so beyond the tip of the blades. In the author's experiments N was varied for any one fan only over a range of 1:3; in Messrs. Morgan and Wood's experiments, over a range of 1:2. These ranges are too small to prove that the N^3 law is followed exactly.

On further reference to Fig. 2, it will be seen that a curve drawn through the mean of Messrs. Morgan and Wood's points would be 2 or 3 per cent higher than the author's curve, and it is somewhat difficult to say whether or not the higher values should be taken.* Values of κ obtained by testing the same engine successively with a fan brake and a Froude dynamometer seem to indicate that the author's values are the more correct. In any case, the discrepancy between the two sets of results is not great for commercial testing.

Resistance Coefficient Easily Affected

It will be obvious that the presence of the engine and flywheel or of a wall or floor in the vicinity of the fan will affect its coefficient or resistance. The author has found that the coefficient of resistance is affected by less than 1 per cent for fans for which r/s is greater than 3, provided that the diameter of the flywheel (to which the fan arms may be bolted) is less than r_0, that the clearance between the tip of the blades and the floor is at least one and a half times the radial width of the blade, and that there is a distance of at least one and a half fan diameters between the plane of the fan and the wall. Too small a clearance between the blade tip and the floor introduces the greatest source of error. If it is not convenient to mount the engine sufficiently high to obtain the floor clearance specified above, a shallow trough should be dug. This should not be deeper than one and a half times the radial width of the blade, and its breadth should be about four times the axial breadth of the blade.

---

*Messrs. Morgan and Wood do not say how the speed of rotation of the fan was measured in their tests. If a tachometer was used, this may have been in error.

They also do not state the temperature and pressure of the air. In analyzing their results the author has assumed that the density of the air was 0.0763, a figure which corresponds to mean atmospheric temperature and pressure.

In fan brake dynamometers as usually constructed it is customary to make the value of r/s small. It will be seen, however, on reference to Fig. 1, that the experimental accuracy is greatest for the larger values of r/s. Further, the shape of the $\kappa.r/s$ curve is more easily defined from theoretical considerations when the value of r/s is large. The curve can, therefore, be drawn with much greater certainty at these values. Then again, the influence of the engine and flywheel on the resistance coefficient of the fan used is less when r is large, and, for fans installed with similar clearances, the effect of the proximity of the floor diminishes as r/s is increased. For these reasons, it is desirable to design the fans so that the ratio r/s is not less than 2.5 or 3.

Not Highly Accurate

The author has usually found that the fan brake dynamometer is not considered capable, under the conditions of ordinary commercial testing, of giving results of any very high degree of accuracy. It would seem to him that if the above points are taken into account when designing and installing the fans, and if the speed of rotation is correctly measured, and if any variations in the temperature and pressure of the air in which the fan rotates are measured and allowed for, the accuracy of the results should compare very favorably with those obtained by much more elaborate apparatus. A summary of the equations and symbols used is given below:

$$\mu_b = \kappa N^2 r^3 s^2 W \quad \dots\dots (1)$$

$$\mu_a = 0.35 \times 10^{-8} \sigma N^2 r_a^4 t W \quad \dots\dots (2)$$

$$\mu = \mu_a + \mu_b \quad \dots\dots (3)$$

$$\text{H.P.} = \frac{\mu N}{63{,}000} \quad \dots\dots (4)$$

Where

W = Density of the fluid in which the fan rotates, in lb. per cubic foot

= 62.33 for water at 50° F.

= 1.347 × barometric pressure in inches of mercury (460 + temp. in °F.)

μ_a = Torque due to arms alone, in inch-lbs.

μ_b = Torque due to blades alone, in inch-lbs.

μ = Total torque in inch-lbs.

H.P. = Horsepower.

N = Revolutions per minute.

s = Length of side of square blade, or diameter of circular blade in inches.

r = External radius of fan in inches.

r_a = Radius of arms in inches, measured to the inside of the blades.

t = Thickness of arms in inches.

κ = A coefficient depending upon the value of r/s and the shape of the blade for fans rotating in free space.

σ = A coefficient depending on the section of the arms as given below.

It will be obvious that the relation

$$\mu_b = \kappa N^2 r^3 s b W \quad \dots\dots (5)$$

where κ is the coefficient for square blades given in Fig. 1, should be approximately correct for rectangular blades of radial width s and breadth b inches. The values of κ calculated from Messrs. Morgan and Wood's tests on rectangular blades by means of this equation are shown in Fig. 2.

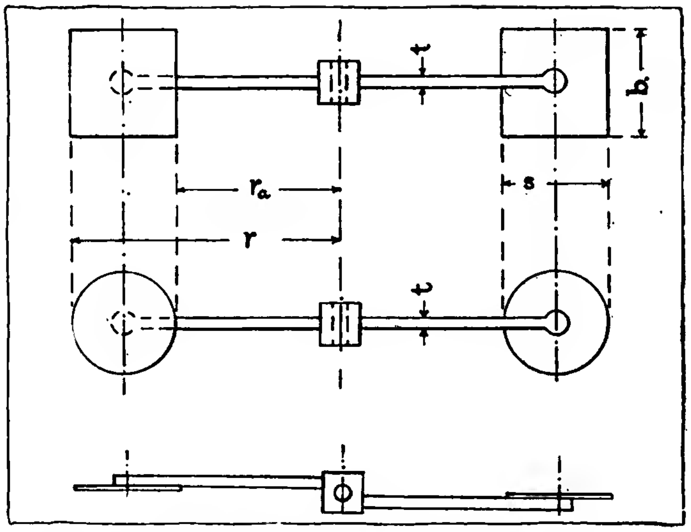

Fig. 3—Measurements of square and circular-bladed fans

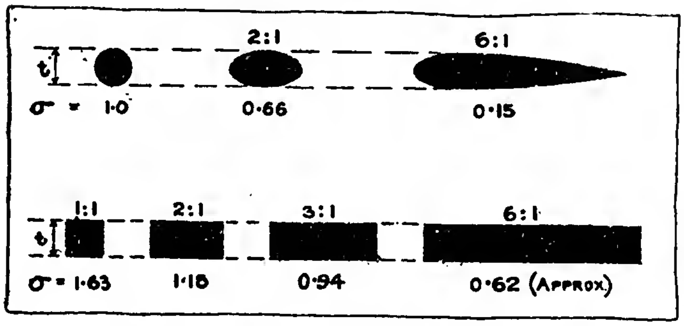

Fig. 4—Values of σ for representative fan arm sections

It is interesting to note that when *comparing* the performances of a number of petrol engines by means of the same fan, no correction need be made for variations in the temperature or barometric pressure of the air, as these factors affect the resistance of the fan and the torque of the engine at any given speed in almost exactly the same ratio. The author would like to draw attention to the theoretical interest of this investigation, in which tests made on small models in water are used directly to predict the behavior of much larger apparatus in air. The conditions under which such comparisons may be made with accuracy, and the economies which are possible by carrying out tests in a dense medium such as water, are further dealt with in a paper by the author on "The Commercial Metering of Air, Steam, and Gas," which is shortly to be read before the Institution of Civil Engineers. In conclusion, the author wishes to acknowledge his indebtedness to the careful work of Messrs. Morgan and Wood, and to thank the Aeronautical Society for permitting him to republish in this paper certain matter which he has already contributed to their journal; also his firm, Messrs. Geo. Kent, Ltd., of Luton, at whose works the tests were made, and Mr. F. Gray, who assisted in the preparation of the paper.

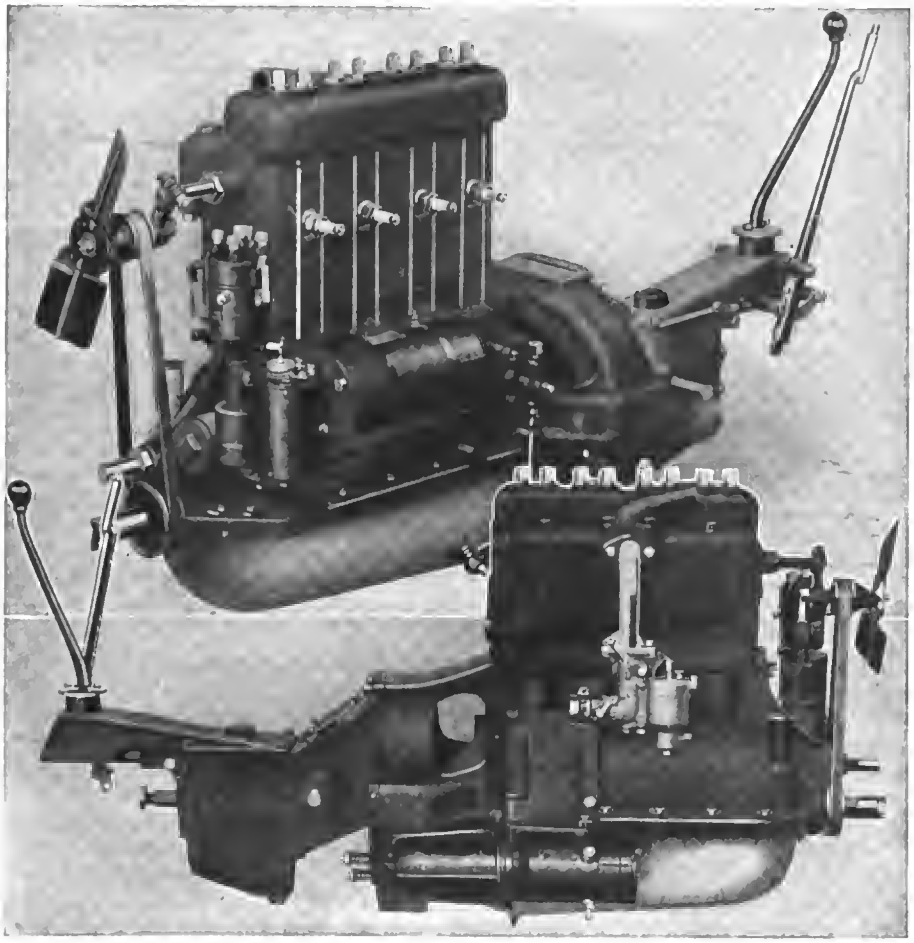
Scripps-Booth Eight Is Four-Passenger

Has Individual Front Seats—Other Models Are Four-Cylinder Roadster and Coupe—Motor More Powerful Than in 1915—Characteristic Body Lines Continued



Both sides of the 3 by 4¼-in. four-cylinder motor used in the 1916 Scripps-Booth roadster and coupé. Above is illustrated the electric generator and ignition apparatus, and below, the mounting of the starting unit

ALTHOUGH it was made known at the New York and Chicago shows that the Scripps-Booth Co., Detroit, would offer for this year a higher-powered four-cylinder model as well as an eight, and some of the details were given it was then too early to obtain complete details of the new productions of this concern, but these are now available and show the main differences are in the power plants.

Like most other automobile manufacturers, the Scripps-Booth company has been obliged to raise the prices of its models somewhat, due to the materials situation, the four-cylinder roadster now selling for $825 and the coupé which is mounted on the same chassis commanding a price of $1,450. The eight-cylinder engine is put in the four-passenger car only, and the chassis for this has a 120 in. wheelbase instead of 110 in., as is the case with the four-cylinder models. This eight is priced at $1,175.

A New Four-Passenger Body

The really new thing in the present Scripps-Booth announcement, however, is the four-passenger body, which follows closely the idea that was prevalent at the shows of making it a sociable affair. There is an aisle between the two front individual seats, this admitting to the rear seat which is 34 in. wide. Entrance to the rear compartment is through the doors at the front seats. The general body lines of this larger Scripps-Booth are the same as those which have been followed in the four-cylinder roadster ever since its inception, and which have occasioned much favorable comment from the motoring public. The radiator is of the V-type and the hood and front of the body carry out the same slope without any disturbing transitory curves. The rear deck of the new body also carries out much of the same shape as the roadster, and there is a wire wheel rakishly positioned at the end of it. The wire wheels, in fact, add a great deal to the appearance of the car.

Overhead Valves on Both

Very little has been altered in the general chassis layout of the new Scripps-Booths as compared with the earlier model, but considerable change has been brought about in the power units. In fact, the influence of the same designer is to be seen in both the new four-cylinder and the eight-cylinder engines, for they both adhere to the overhead valve construction with adjustment for the rockers outside in an exceedingly convenient position. The four has a bore of 3 in. and a stroke of 4¼ in., whereas the eight is 2⅝ by 3¾ in. Needless to say, the new four, with its larger motor, has considerably more power than the 1915 motor, and like the eight, is very accessible for various adjustments or repairs.

Two-Unit Electric System

A change of importance is the fitting of a two-unit starting and lighting system of Wagner make to replace the single-unit system that was formerly fitted to the roadster. The starting motor is placed on the right and close to the flywheel so that it can connect with the flywheel for performing its function. The popular Bendix automatic meshing and de-meshing apparatus is used, whereby the operation of throwing on the starting current by means of a switch in the footboard automatically meshes a pinion on the starter shaft with teeth in the flywheel rim, and once the speed of the engine exceeds that of the starting unit this pinion de-meshes again. The details of this starting connection have been thoroughly covered in previous issues, and are well understood by the public. The starting motor is entirely out of the way, being hung from a bracket below the upper part of the crankcase.

On the four the generator is carried on the left and is driven by the camshaft through inclosed gearing. In the case of the eight the generator is carried in the block between the cylinder castings, and is driven by a belt.

Adjust Valves While Running

One of the motor illustrations herewith indicates clearly how the overhead valves are inclosed completely at the top of the motor. Adjustment of the clearance between the end of the valve rod and the rocker which actuates the valve stem is afforded by the adjusting nut which protrudes through the top of the plate. By means of these adjustments it is possible to adjust the valve clearance while the engine is running if desired. First the cap which goes over the adjustment proper is removed and then a screwdriver may be used to turn the slotted head of the adjusting nut, the locking nut having to be loosened first. An experienced person can tell by the feeling of the valve rod just how much clearance there is. This valve adjusting scheme has been described in previous issues in connection with the Ferro eight-cylinder engines designed by the Brush Engineering Assn.

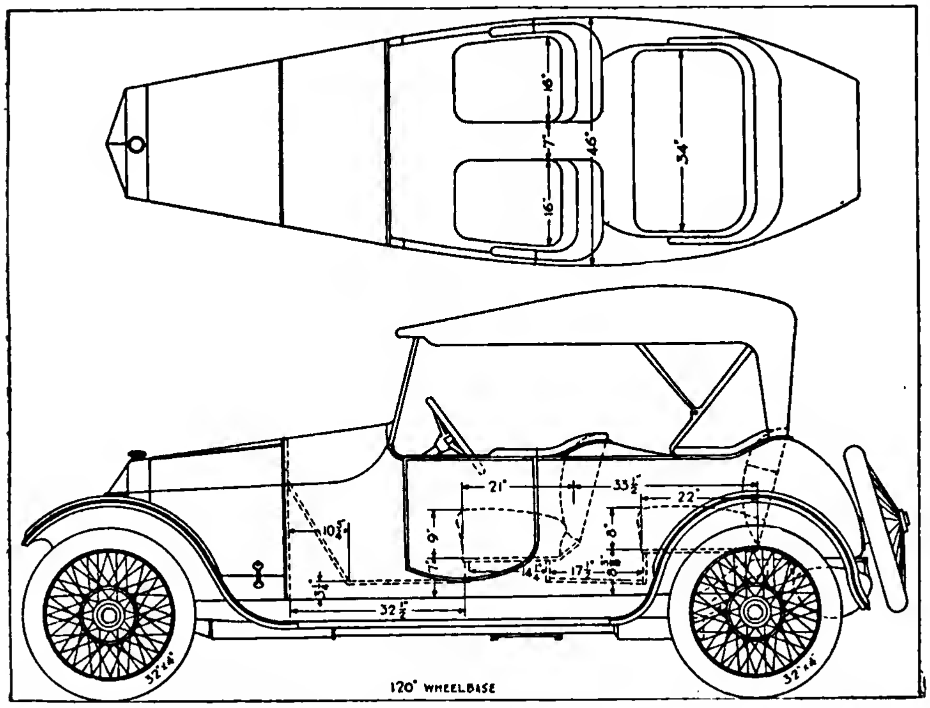
Motor Mounting More Rigid

Support of the four-cylinder motor in the chassis has also been changed. Instead of hanging the rear end from a bridge, the back part is supported directly in the frame on either side. This makes a more rigid mounting.

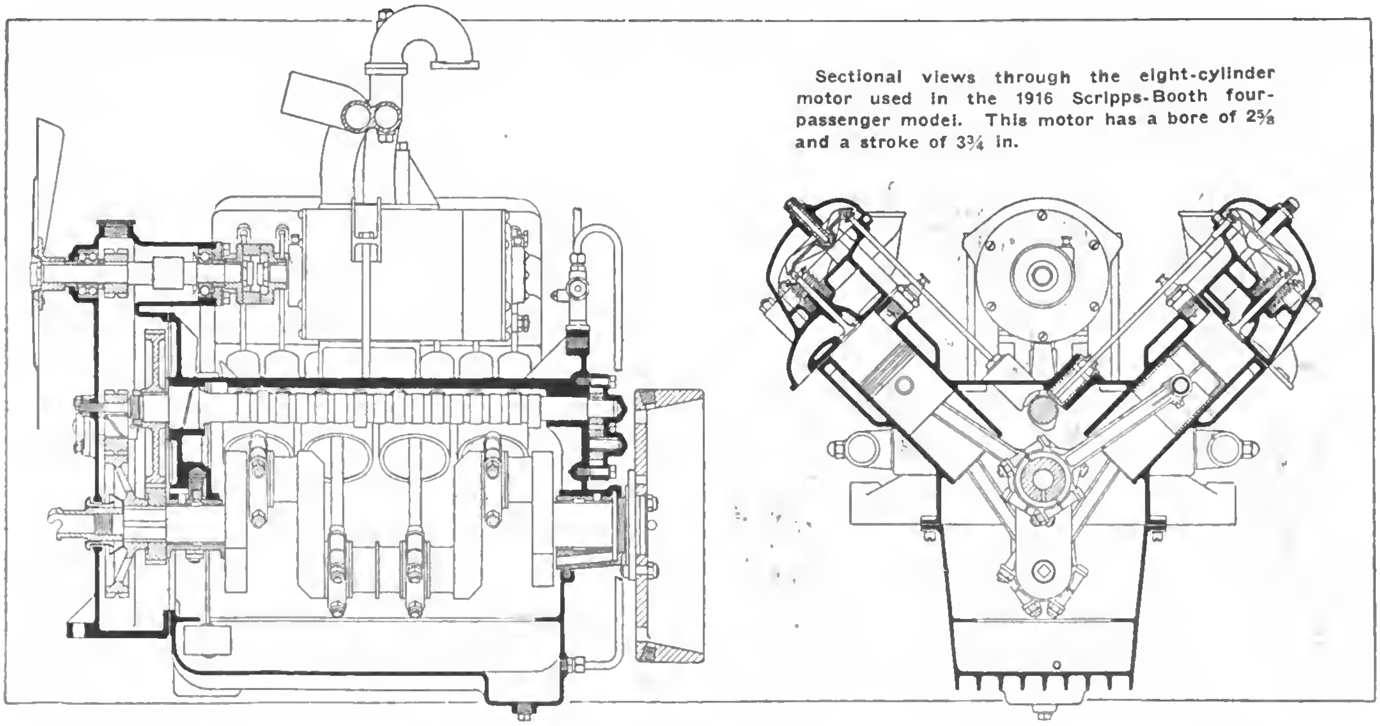
Remy ignition is fitted to the new motors and the means of attachment and drive on the four is clearly brought out in the illustrations. The distributer is vertically mounted, so as to be driven by a worm gear off the front end of the camshaft. The coil is mounted in close proximity to the distributer and both are adjacent to the generator. Centralization of the electric apparatus is the result and it tends to shorter wiring. As the spark plugs are carried in the left side of the cylinder block, it is difficult to see how they could be brought much closer to the distributer.

No External Manifolds

Simplicity has evidently been striven for in the application of other motor accessories in addition to those already mentioned, a fact which is forcibly brought out by the mounting of the carbureter on the right side and the absence of external manifolding. Distribution of the incoming gases is cared for within the cylinder casting, since there is but a single opening for connection to the carbureter. The exhaust manifold is of large proportions and therefore gives free exit for the burned gases.



Layout of the new Scripps-Booth four-passenger body which is mounted on the eight-cylinder chassis for 1916, showing some of the principal dimensions



Sectional views through the eight-cylinder motor used in the 1916 Scripps-Booth four-passenger model. This motor has a bore of 2⅝ and a stroke of 3¾ in.

The oil pan is a pressing which attaches in the usual manner to the bottom of the crankcase and is sloped to send the oil back to the reservoir at the rear, from which it is drawn by a pump and delivered to the troughs under the connecting-rods. This is what might be termed a circulating splash system and applies to the four-cylinder motor only. On the eight the lubrication system is of the pressure type, in which the oil is fed by a pump to the motor bearings, and thence through drilled passages in the shaft to the crankpins. It is not splashed.

Eight's Maximum 2500 R.P.M.

These new Scripps-Booth motors attain moderately high speed, the four having a maximum of 1800 r.p.m., and the eight running up still higher to 2500. The reciprocating parts have been designed to take care of the speed running with a marked absence from vibration. In both designs the crankshaft and camshaft are each carried on two bearings of the conventional plain type.

Back of the motor there is practically nothing new to the chassis. A multiple disk, dry plate clutch is used and a conventional form of three-speed gearset that is very compact and bolts to the semi-housing that covers the top of the flywheel and is an integral part of the cylinder casting. The rear axle is a three-quarter floating type, to which the power is conveyed by an open propeller shaft fitted with two universal joints. Front springs are semi-elliptic and the rear set are of cantilever type. In the braking system, the use of piano wire cable to connect the brake operating levers with the grounds. These cables are provided with a very easy form of adjustment to take up the slack and have the advantage of extreme simplicity along with freedom from rattles. Scripps-Booth, in fact, is the pioneer in this form of brake control.

Vacuum Fuel Feed on Four-Passenger

One other new feature of the four-passenger model is the use of the vacuum system of supplying the fuel to the carbureter, the supply tank being carried at the rear below the wire wheel deck.

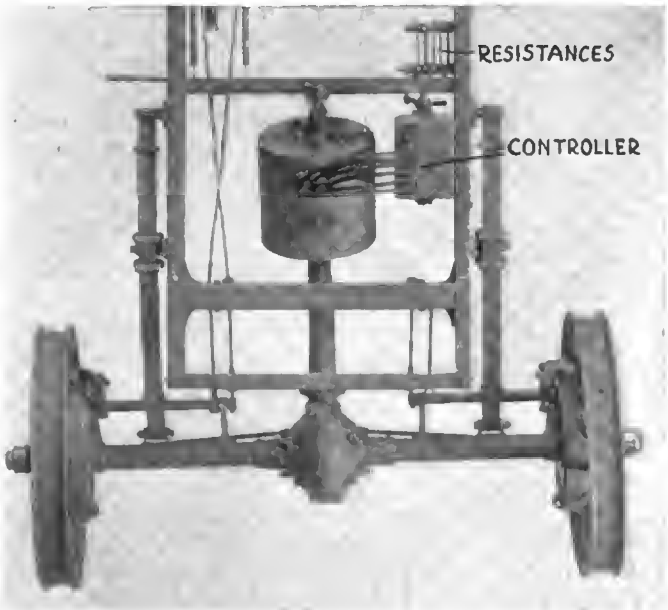
Some of the dimensions of the four-passenger body which the Scripps-Booth designers have been able to fit to the wheelbase of 120 in. will indicate the cleverness with which all of the available space in the body has been used to advantage. From the front to the back of the front seats the dimension is 21 in. and they are 16 in. wide with an isle between that is 7 in. wide. The greatest width inside the body is 46 in., and from front seat to back seat is 33½ in., the distance from the front of the front seat to the front of the dash being the same amount. Easy riding in the back seat of the new four-passenger is fostered by bringing the seat sufficiently forward so that the passengers really sit ahead of the rear axle with the obvious advantages resulting from such a position.

Tire equipment of the eight-cylinder model consists of five 32 by 4 tires carried on wire wheels. One extra tire and wheel are also supplied to the four-cylinder cars, the tires in this case being 30 by 3½.

Milburn Adds a Brougham to Its Line of Electric Cars

New Model Will Sell at $1,585 and Is Mounted on Same Chassis as the Roadster

The new Milburn electric brougham selling at $1,585



Rear of Milburn chassis which carries the new brougham

BESIDES continuing its model 15 chassis on which are mounted the coupé and roadster models, the Milburn Wagon Co., Toledo, Ohio, has added to its line of electric cars a new model. This is a brougham to be known as model 22 and sells for $1,585, being designed primarily for those who desire a larger electric than the other models.

The brougham is not unlike the coupé in appearance, but considerably larger. It measures 63½ in. from front to rear glass; its doors are 26½ in. in width and its cushions are wider and deeper than those in the other cars. The windows are raised and lowered by the Dura mechanical window lifter.

New Car Is Not Heavy

Although the new model is larger and even more luxurious than the company's former models and has a wheelbase of 105 in. as compared with 100 in., and 32-in. wheels as compared with 30-in. wheels on the coupé, it weighs but a few pounds more than the latter. Improvements in designing and the use of steel drop forgings and high grade steel have made this possible.

Cantilever Springs in Rear

Cantilever springs are used in the rear, which give the best possible riding qualities; General Electric motor and controller are used and the spring bolts are provided with self-lubricating bushings, which obviate the necessity of turning up grease cups; the standard battery consists of twenty-two cells of 17 W. T. X. I. Philadelphia diamond grid plates. For those who desire even greater speed than normally provided, a larger cell equipment is offered at a small additional expense. Edison batteries also can be obtained at extra cost.

The FORVM

KEROSENE MUST BE NATIONALLY DISTRIBUTED—NO DRAWBACK TO TRANSVERSE STEERING LINK MOUNTING—EFFICIENCY IN CAR COLORS

Difficulties To Be Met in Kerosene Carburetion

By E. H. Sherbondy

Clay & Sherbondy

IN review of the use of kerosene and heavy oils in automobiles and trucks the first matter of importance is that of distribution of kerosene. We now have nation-wide distribution of gasoline, a matter which has required a great deal of thought and effort on the part of refiners and manufacturers, and really good distributing facilities for gasoline have only been available for about four years past.

May Use Heavier Fuel Oils

If the refiners do not develop commercial methods of distillation, which very largely increases the yield of gasoline, or more properly motor fuel, it will undoubtedly be absolutely imperative to operate at least a part of the motor vehicles on the heavier fuel oils, kerosene, benzol, etc. It is therefore apparent that one of the first steps will have to be to arrange the distribution of kerosene in much the same manner as has been done with gasoline. It is not now possible to conveniently purchase kerosene in quantities for motor vehicles.

The next step of importance is to adapt that class of motor vehicles which most readily lend themselves to the use of kerosene for a fuel. Unquestionably the motor truck will come first, especially the slow-speed, heavy type truck.

There can be no doubt whatever that the cost of distribution must increase the price of kerosene, when such distribution is arranged broadcast as is now the case with gasoline.

Because the truck motor carries a very much heavier normal load (b.hp.) than the pleasure vehicle, it operates with a higher average compression, and within a narrower speed range, thus approaching conditions met with in the operation of stationary and marine engines. All of this is favorable to the use of kerosene as a fuel.

Disadvantages of Jacketing

For many years past, marine and stationary four-stroke cycle kerosene engines have used vaporizing chambers to effect the carburetion of combustible mixtures, and the general method pursued has been to jacket the vaporizing chamber and heat the liquid fuel-air mixture by means of the exhaust gases. There are a great many disadvantages to this mode of procedure, since with varying load, the heat available in the exhaust gases varies and is greatly reduced during closed throttle operation, and when operating at full load too much heat is supplied by the exhaust gases, resulting in serious decrease in the volumetric efficiency. The slow choking up of the vaporizing jacket chamber is also a problem encountered, and is caused by partially burned fuel and lubricating oil vapor being thrown into the exhaust passages when the motor is throttled close. (Poor vaporization and great depression in the cylinder during suction stroke.)

A kerosene vapor-air mixture cannot be compressed more than 47 lb. above atmosphere without encountering preignition and severe pounding, excepting when water injection is used to reduce the compression temperature. The quantity of water necessary is from two to five times the quantity of fuel supplied, depending on the homogeneity of the mixture.

When using a vaporizing chamber in connection with an ordinary metering device, such as a gasoline carbureter, the distribution of the fuel particles throughout the volume of air aspired is usually very poor, and when combustion takes place within the motor cylinders the localized oil vapor is subjected to a cracking process, in which hydrogen gas is liberated and solid carbon particles are formed, part of which adhere to the walls of the combustion chamber, and part of which are rejected with the exhaust gases. The carbon formed in this way may be of two varieties, amorphous or crystalline. Amorphous carbon will be readily consumed under full throttle conditions, and its formation is not particularly detrimental, but crystalline carbon is formed under very different conditions than the amorphous variety, and requires enormous temperatures for its combustion to be effected. Adhering to the combustion chamber walls, whose temperatures are always relatively low, crystalline carbon builds up in the manner well known to motorists in the case of gasoline engines.

The use of water is a further palliative in motors operating on kerosene, since the steam particles act as carrying agents for the carbon, and tend to prevent its formation within the motor cylinders.

Combine Carbureter and Vaporizer

The best solution for the use of kerosene in present design truck motors is to build a combined carbureter and vaporizer, in which a very thorough distribution of the fuel throughout the air is arranged for, so that a homogeneous oil-vapor-air mixture is supplied to the motor, at as low a temperature as is possible.

It is extremely important that the constant level chamber and metering orifice of such a device be not greatly heated, since the changes in viscosity in kerosene at varying temperatures will upset the mixture proportions, which may have been determined for any initial temperature and size of metering orifice.

Two Methods of Starting

Two methods of starting are available with vaporizing carbureters. One is to start the motor on a small quantity of volatile liquid fuel and then utilize the heat of the exhaust gases for vaporization of the kerosene after the motor has started. The other is to burn part of the kerosene which has passed the metering orifice, in what may be termed a producer chamber, to insure vaporization of the oil fuel required in the combustible mixture. The products of combustion, oil vapor and air may be very thoroughly intermingled and then supplied to the motor cylinders through the usual intake manifold. Ignition in the producer chamber may be started, and if necessary continued, by means of high-tension electrodes disposed within the producer chamber and

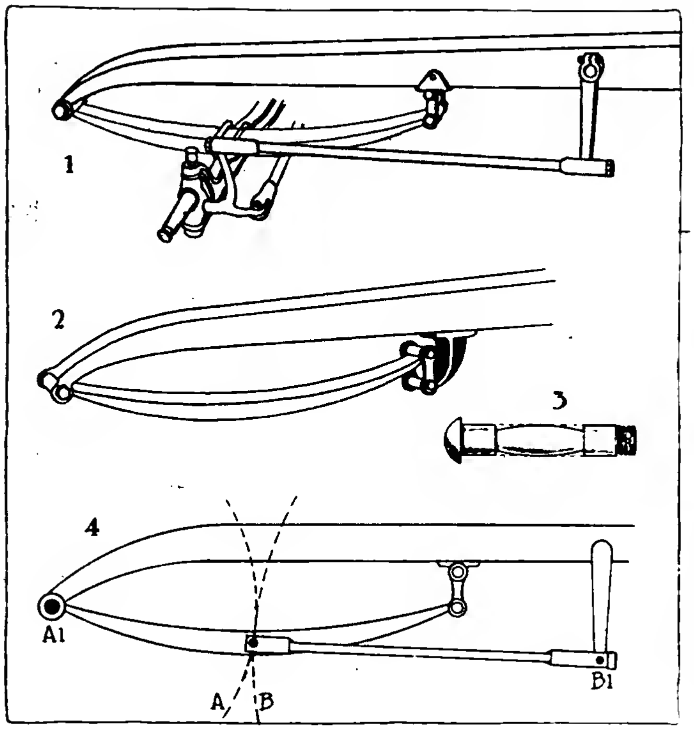


Fig. 1—Usual fore and aft type of steering link. Fig. 2—A pull shackle as an improvement on the push variety. Fig. 3—How a front spring bolt usually wears. Fig. 4—Cause of front wheels wobbling

arranged to discharge the current supplied from a high-tension vibrating coil and battery system.

Another means is to use a blast lamp for initial heating of a "hot tube" disposed within the producer chamber.

The very rich and highly heated oil vapor produced in this way must be reduced in temperature, before admixture with the main air supply, in order to prevent combustion of the entire fuel within the intake manifold.

Even with such carbureting devices as outlined, operation is not entirely satisfactory, nor is combustion complete.

A constant load, with compression in the neighborhood of the limiting values, makes possible only fair operation, with fuel consumption greatly in excess of what would be the case were gasoline used.

Further, because "localized" oil vapor in the charge is usually the rule, rather than the exception, combustion proceeds during the entire expansion stroke and sometimes during the entire exhaust stroke. Of course this results in enormously increased heat losses to the walls of the cylinder and requires more active cooling.

Temperature Changes Are Factors

Oil engines of all varieties are very sensitive in operation to temperature changes, usually because part or all of the vaporization of the fuel depends on the heat of compression to effect the vaporization. In oil-vapor-air mixture engines, low temperatures result in condensation during the suction stroke to a greater or less extent, and high temperatures cause pre-ignition, firing compression of the mixture.

The real solution of the vehicle oil motor problem lies in a rational design and construction of a motor to suit the fuel, and the future freight automobile and probably the aeroplane must have motors capable of highly efficient operation on heavy oils.

It should be the immediate business of the S. A. E. and the National Automobile Chamber of Commerce, Inc., to investigate thoroughly the possibilities of present design carbureters and vaporizors for use with kerosene. For the future necessity of the industry, a concentrated effort should be made to break away from tradition and evolve new types of internal combustion engines which will embrace the present facility of operation and reliability possessed by light fuel oil motors, together with efficient operation on heavy fuel oils.

Transverse Steering Link Not Objectionable

By Theo. D. Stanley

General Service Engineers Co.

THE article by H. H. Dyke in THE AUTOMOBILE for March 23 on "Faults in Front Spring Suspension" has come to my attention, and appears in error in one or two particulars.

In the description of the effect of up and down movement of the car as producing a movement of the axle in the arc *A*, Fig. 4, because anchored at one end *A*1, if there was no flexibility this would be true, but, owing to the spring deflection, another reverse arc is created. The increasing or straightening of the curvature of the spring produces a shortening or lengthening of the distance between the axle and the forward end pivot or anchor of the spring, producing a slight lengthening or shortening of the wheelbase of the car. This movement still further accentuates the action noted by you.

It does not appear to me there is any "obviously undesirable" reason why a steering link should not run crosswise to the car, but, on the contrary, some advantages.

In the mounting of the steering-gear, the farther forward it is placed, the less distortion by the rear wheel and spring deflection is produced to be added to the fore wheel displacements in the fore and aft steering-gear mounting.

The link connections are longer and possible of suitable curvature, for those parts in equipping by cross link method as indicated in A. L. Clayden's article on Improving the Steering in THE AUTOMOBILE for Sept. 2, 1915, create an arc of greater radius.

Since the tie rod has to cross the car, there is no reason why the link should not, and with a full irreversible steering-gear is, theoretically, the best way with present form of spring suspension.

Lighter Colors Are Most Efficient for Cars

By M. C. Hillick

THE AUTOMOBILE has consistently and with convincing logic set forth, in past issues, the drawbacks and disadvantages of the blacks and blues and greens, the two latter of the deepest shade, as colors for use upon automobiles. These pigments, it must be conceded, are, at the outset of their career on the surface of the car, and when given the full radiance of a fine fabric of varnish, exceedingly beautiful to behold, and if they could be made to wear on with the same magnificent effects, and at the minimum outlay of cleaning processes be maintained at a high rate of efficiency under the stress of everyday service, their value and usefulness would pass unquestioned. Unfortunately this is not the case, and wherever these colors are found doing service on the average American highway, there you may expect to find difficulty in keeping them clean and neat, and showing a reasonable amount of luster. Moreover, they are colors ground in japan, and therefore afflicted with a brittleness which under severe road and garage treatment is certain to suffer. They will, of course, give a better account of themselves if kept well protected under an ample supply of varnish, but in the face of all that may be done for them—speaking now of the colors used upon the cars exposed to the conditions of the average country and village highway—the tendency is to show a dingy, unkempt, and generally unsatisfactory appearance.

Must Consider Conditions

The exception to this rule is the color used upon the car employed for service upon city pavements, where the conditions of service are of a modified order, as compared to those encountered in the rural districts. These black, deep blue and green colors require a dressing-up with some of the ornamental embroidery of relief colors to take them from under the funereal aspects which such field colors always invite. In other words, they require an artificial stimulation to keep them in presentable condition for even a temporary show.

In respect to the employment of lighter colors, such, for example, as maroon, some of the browns, the grays, creams, wine and the lakes. These colors, some of them also ground in japan, have the important advantage of being comparatively easy to clean up and to be kept clean. Also, they retain their brilliancy of effect to the maximum limit. They show dirt less than darker colors, and respond to the cleaning operations quicker. They render service in proportion to the attention bestowed upon them but at the same time they flourish under neglect and display color effects that would make the darker pigments look like a vain show. The grays, and the creams, and lighter yellows, all are permanent pigments by virtue of the ingredients composing them, white lead being an important one, and a basic feature of the greatest value as a surfacing medium. Such a pigment, naturally supple and elastic, imparts to the color a surfacing property, a density of fiber and film, and an elasticity quite unsurpassed, and explains the tenacity and the durability which characterize these pigments with a pronounced lead base. Give these colors a proper fabric of varnish, and a decent measure of care taken, including proper washing processes, and the service they will render cannot fail to equal that of the very best pigments.

Stand Washing Well

Practically all these colors stand washing and cleaning operations excellently, which may be accepted as evidence of their durability and strength of film. Likewise, they show road dirt and the accumulations of the highway less than the darker colors. They require less of the ornamental effects to bring them into notice, the field color being capable of making an impression without the aid of any ornamental lines, although, of course, these lines serve to lighten the effect and bring into greater relief the true and distinctive character of the field color.

White Lead Gives Elasticity

All colors having a portion of white lead in their composition may be accepted as pigments of an elastic nature, and capable, under reasonable conditions, of giving a masterful measure of durability, at the least possible outlay on cleaning and renovating. The black and the darker colors referred to fail in the capacity to stand the renovating processes without detriment, especially when the protection of varnish has become of no effect, whereas the lighter colors bear these erosives with fewer indications of injury to their luster and general appearance. In making choice of color for the car, its class of service may well govern the selection.

Robbins & Myers Clubrooms for Employees

THE Robbins & Myers Co., Springfield, Ohio, is one of the progressive companies which have established clubrooms for their employees. About two months ago this company organized and equipped at its own expense a club which is now occupying the entire fifth floor of the Bushnell Annex, Springfield, an office building in the down-town part of that city.

The club is for the use of employees only and no charge is made for membership, all expenses being paid by the company. The membership is composed of the male employees only, and there is no separate club for female help connected with this particular club; however, at the factory building a music room, rest room, and other conveniences in the nature of a club is provided for the female employees.

The club contains a reading room and lounge, pool and billiard room, large dance hall and auditorium. These have proved popular with the employees who have made a good attendance every evening since it has been opened.

About once a month a speaker is engaged to address the club members in the auditorium and a banquet or buffet luncheon is served at these meetings. The auditorium is also used by a band composed of the company's employees.

A manager is employed by the Robbins & Myers Co. to run the club, and there are no officers other than the factory superintendent of the company, who is in charge.

Middle — Fleet of White trucks loaded and awaiting the order to go to Casas Grandes with aupplies for the American columna pursuing the Villa bandits

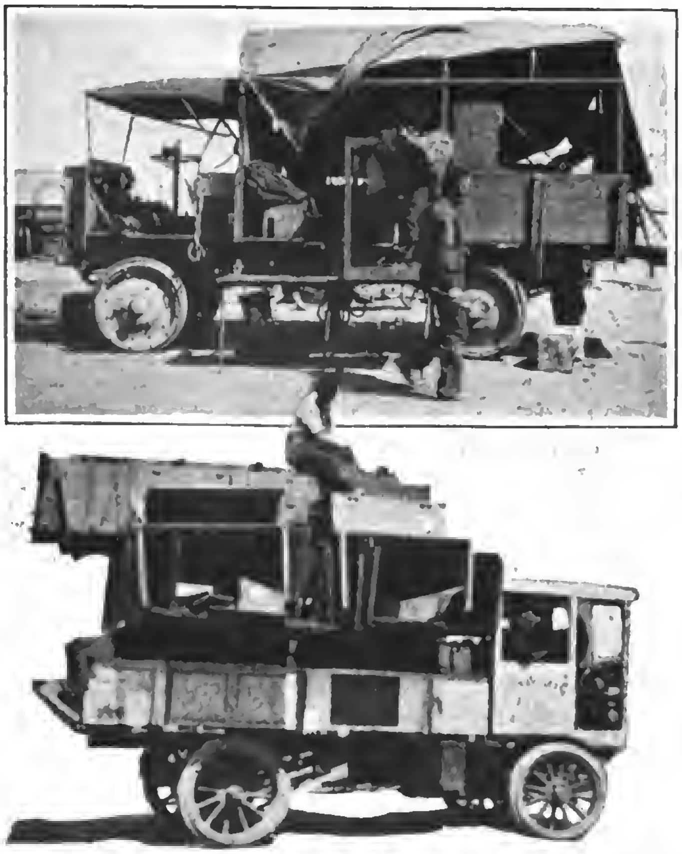
Bottom—White army trucks on the road to the field base at Casas Grandes

Pursuit of Bandits into Mexican Deserts

EL PASO, TEX., March 26—It was but a few days ago that government orders were received at the Packard and Jeffery plants for a squad of trucks for Mexican service. Day before yesterday the chassis arrived here; this morning the entire fifty-four, fitted out with regulation U. S. Army bodies, set out on their 20-mile trip over border roads to headquarters at Columbus, N. M., fully equipped, each with a full load of army supplies, and not so much as a single screw missing.

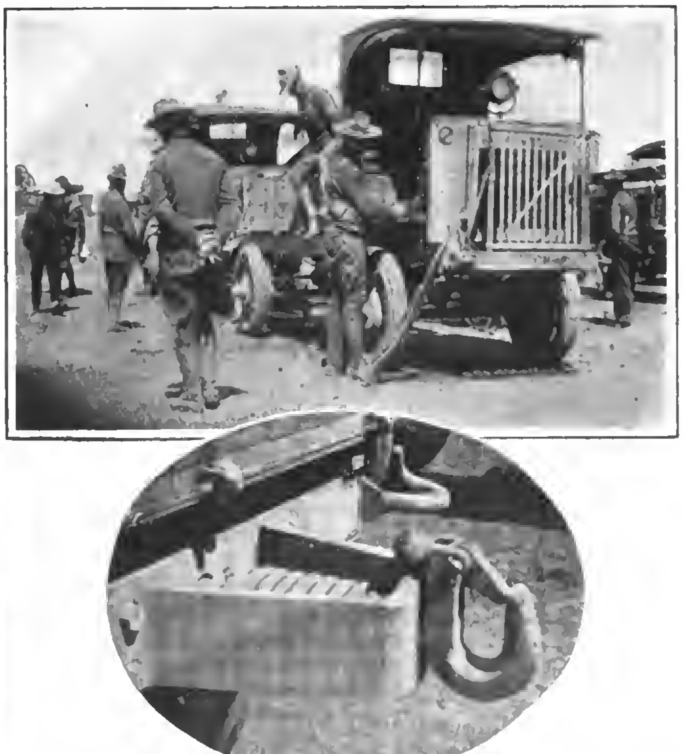
Hardly had the trucks been driven off the flat cars under their own power than a crew of carpenters went after them with hammer and saw and the regulation army bodies were fitted at the rate of one every fifteen minutes. These, bodies, taken from two-mule-team army transports, are equipped with side boards and easily hold the 2-ton capacity of the trucks, in compact army supplies.

The civilian drivers, recruited in Detroit and Kenosha, fitted out in regulation army uniform, were eager to get under way, and made a decidedly businesslike impression as they lined up for inspection before the start. Each man is equipped with a big .45 army automatic, cartridge belt, canteen, sweater jacket, knickers, canvas puttees, substantial tan army shoes, khaki shirt and the regulation U. S. sombrero. Truckmaster Carl W. Newell has been connected with the Packard service in Mexico for six and a half years and is thoroughly familiar with the territory in which his charge of twenty-seven trucks will operate. Truckmaster E. H. Mahoney of the Jeffery contingent is confident of the success of his cars in the desert country, as the squad which preceded him has demonstrated their efficiency.



Above—A Jeffery quad fitted with a completely equipped machine shop. Below—A load of bodies for the new trucks

Upper—General view of the camp at Columbus, N. M., looking toward Mexico. Middle—Jeffery quads with bodies completed. Lower—Some of the trucks loaded and waiting the word to start



In the foreground of the upper illustration is the first Jeffery quad to make the round trip to the front at Casas Grandes, Mexico. Below is shown the substantial Jeffery coupling

Mack 2-Ton Armored Truck for N.G.N.Y.

First Vehicle To Be Completed Carries Two Guns

Mack AC 2-ton armored truck for N. G. N. Y. motor battery

AN armored motor truck battery, with a quota of 160 men and six officers, has been formally mustered into the New York National Guard. For its equipment, which will probably comprise ten vehicles, four experimental armored cars are being prepared. These are to be built on the following chassis: a 2-ton worm-driven AC Mack, a White 1½-tonner, a four-wheel-drive 2-ton Jeffery, and a Locomobile six-cylinder touring car chassis; there is also a 2-ton four-wheel-driven Jeffery with a steel service body. Funds for this equipment were provided by Judge E. H. Gary, H. C. Frick, Col. R. M. Thompson, D. Olcott, J. N. Wallace and Capt. H. G. Montgomery, who will command the battery.

New Rear Drive Steering Device

A new device to provide rear-end drive has been developed and will be applied to all of the vehicles. This consists of a dummy steering wheel and an electric signal at the rear by which an indicator on top of the front steering wheel will be turned, permitting the rear steersman to direct the actual steering by the driver when running backward. This is considered superior to the dual-steering means which has been used in Belgium and experimented with in this country, owing to the concentration of the actual driving at one point and to the elimination of the lost motion which seemed inseparable from the other construction.

The Mack AC Armored Truck

The International Motor Co. has just finished the construction of the Mack armored truck. This is the heaviest of the experimental types and is fully armored. The chassis is the AC model of 2 tons' capacity and with the body and equipment weighs 9052 lb.

It is designed to carry two rapid-fire guns, ammunition and a crew of gunners. The armor is made of a special heat-treated steel of great hardness and resists regulation U. S. Army rifle or machine gun fire at 50 yd. It completely houses every portion of the chassis and practically every surface is above the wheels on such a slant that bullets will be deflected.

It consists of four sections; the hood, the cab and two body sections, each of which has its own angle-iron frame. Each unit is capable of being dismounted separately, and with the two rear sections removed, a platform truck for the transportation of supplies is formed. It stands 100 in. high overall, the armored sides extending down to within 1½ ft. of the ground and up to a height of 6½ ft. The floor is about 2¾ ft. above the ground and the sides extend 3¾ ft. above the floor, so that in a sitting, kneeling or crouching position, the men are entirely protected.

Two Rapid-Fire Guns

The armament consists of two rapid-fire guns, mounted on fixed tripods, fitted with barbettes or shields which extend above the armored sides. One of these is located in the front section of the body and on the right side and the other at the rear and to the left. For rifle fire, seven loop-holes or ports, with sliding shutters are provided, one at the rear, two on each side of the body and one on each side of the cab. The wheels are of wood with steel disk armor, the rear wheel being half covered by the armored sides.

The motor occupies the front portion of the vehicle, as usual, the radiator in front being protected by a curved steel box. This box has a large air opening at the bottom, below the bottom of the radiator, above which is a sheet of armor which effectually prevents bullets reaching the radiator, either directly or by deflection, regardless of the direction from which they come. The motor hood is hinged at the dash and may be raised entirely, or the two sides, hinged at the eaves, may be raised independently. The armor belt extends down below the crankcase, so that bullets intended for the crankcase will be stopped.

Driver's Seat Is Low

So that the driver's cab may be below the range of the guns, the driver's seat is very low, as in racing cars, and protected by a deep cowl. This cab is 4 ft. 4 in. long and 4 ft. 7 in. high. The driver sits at the left. The cowl is fitted with two ventilation doors at the top, the right one of which carries a Gray & Davis 10-in. searchlight on its bottom, so that when the door is opened, it extends upward. On the roof of the cab is a hatch, hinged at the front, which provides ventilation and may serve as an additional shield to the rear portion. At the front of the cab is a shutter hinged at the top and extending the full width, which is adjustable to provide a wide or narrow vision for the driver. Two rear-view mirrors are placed in front of each cab port-hole to give the driver a view behind.

No roof is provided, and there is only one door, which is at the rear. The rear wheels are given clearance under the low floor by steel wheel houses. All doors, hatches, etc., have either refrigerator type latches or wheel-nut hold-downs.

Electric lighting and starting are features, so that the motor may be stopped and started while under fire without exposing any of the men to fire. Besides the disappearing searchlight, there are two headlights and two tail lights. Both of these are placed very low, so as to concentrate the light on the ground and prevent its carrying any great distance.

Ignition Circuit Is Separate

The storage battery used for lighting and starting is separate from the ignition, the latter being supplied by a Bosch magneto and a dry battery. There is an electric dash light under the cowl to light the instruments and a socket for an extension light. Two fire department kerosene lanterns and two Pyrene fire extinguishers are mounted inside the body. A tool box is placed to the left of the driver's seat.

The radiator is of specially large size to insure cooling under difficult operating conditions and to compensate for the somewhat restricted air circulation. The fuel tank is located below the floor, completely protected by the armor and feeding by the Stewart vacuum system.

For towing purposes, a special spring-cushioned drawbar is provided at the rear, anchored to the rear frame cross-member and extending in a ring back of the rear armor plate.

As most of the armor slopes toward the top, the joining of the plates has been difficult. For this reason and also to prevent chipping the edges of the plates by bullets, butt straps are provided at all joints, thus making these doubly strong and preventing opening of seams.

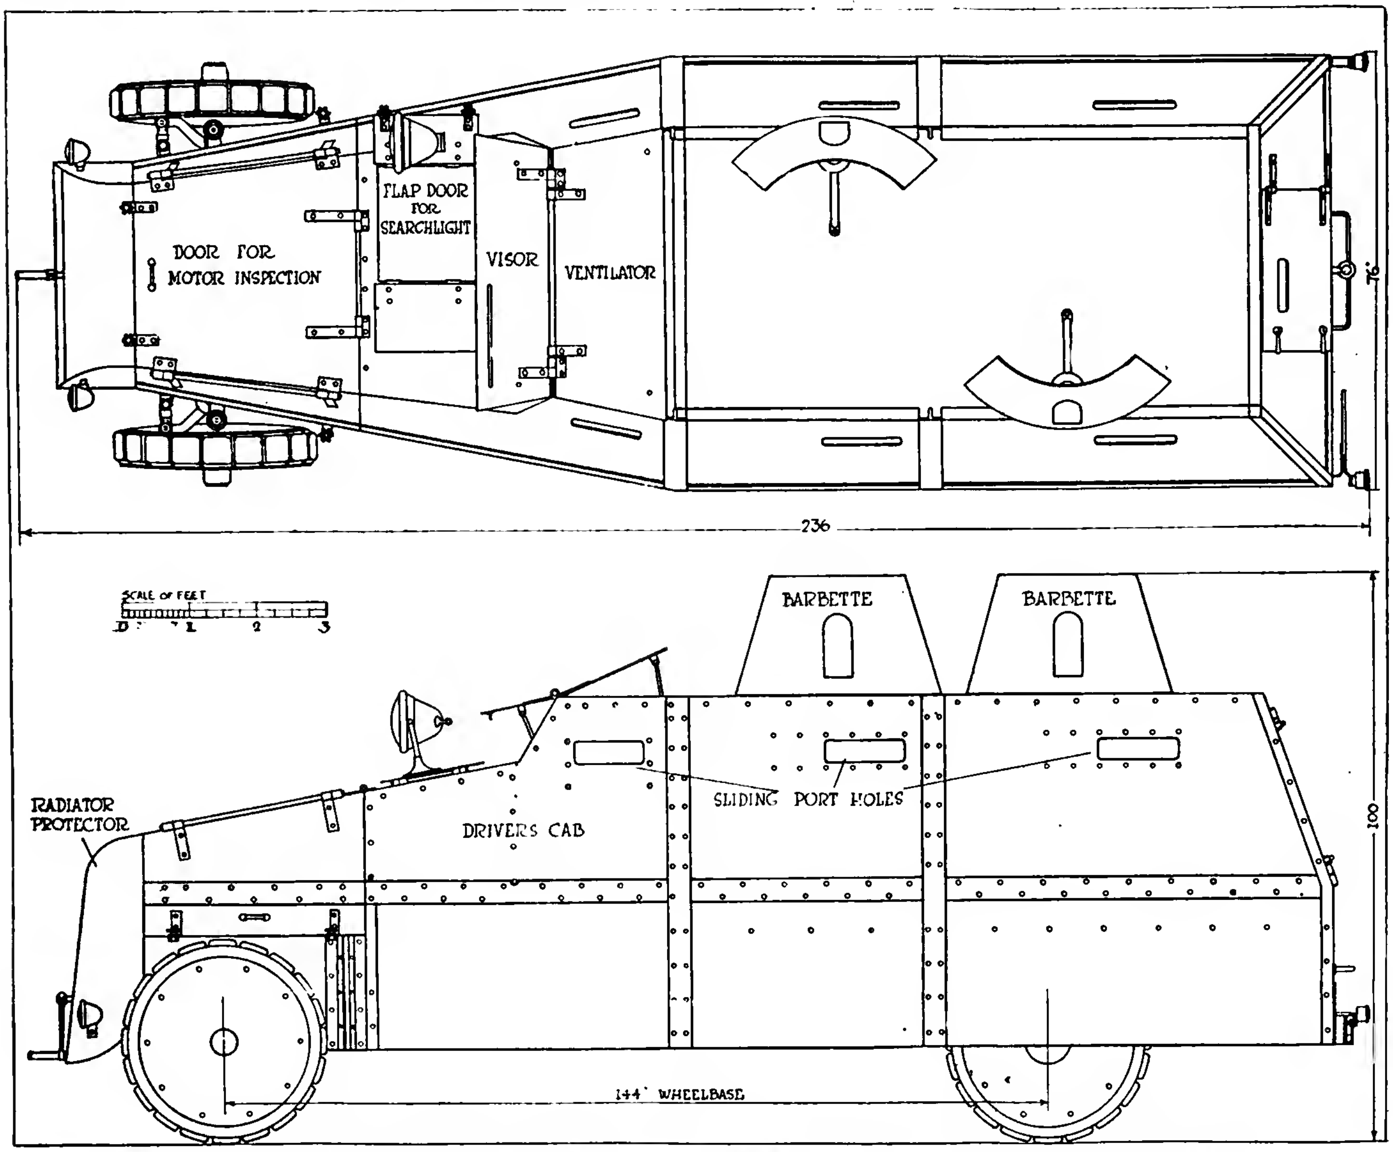
Armor Plates Heat Treated

To illustrate the painstaking care with which this armor has been constructed, the armor itself is cut and drilled at the steel mill and then the plates straightened to conform exactly with the drawings. They are then heat-treated and cannot be drilled or machined again without re-annealing. All bolts and nuts used in the construction of the armor are of special steel, heat-treated and hardened, to prevent their being shot away. There are 600 of these bolts.

Barbettes are mounted on cast bronze frames and are arranged to pivot fore and aft and to swing from side to side. Their backward slope not only provides for bullet deflection, but permits of considerable elevation of the aim, useful in case of use in anti-aircraft work.

Detail weights of the different components follow:

Part	Lb.	Part	Lb.
Chassis	5000	Extra wt. radiator	15
Armor	2400	Fuel tank, etc.	50
Frame for armor	600	Battery	67
Platform	200	Butt straps	250
Drawbar	40	Special bolts	60
Radiator guard	120	Barbettes	250
Total	9052		



Plan and elevation of the 2-ton Mack AC armored truck. Complete with body and equipment, it weighs 9052 lb.

The History of the American Automobile Industry—24

Clerk's Two-Cycle Engine First Construction to Avoid Infringement of Otto's Patent—Selden Begins Work on a Brayton-Type Engine—His Patent of 1895

By David Beecroft

AFTER Nicolaus Otto developed the first four-cycle explosion type engine in 1877, and demonstrated its practicability, it was not long before the general value of this engine was recognized, and as it was broadly covered by patents manufacturers had to pursue one of two courses, namely, pay royalty on the Otto design, or develop some different type of engine which produced fairly satisfactory results and did not infringe on the Otto patents.

Clerk's Two-Cycle Engine

A pioneer in this development of a different type of engine was Dugald Clerk, an English engineer, still living, and looked upon as one the greatest authorities to-day on the explosion engine. Clerk has a large following abroad and visited this country some years ago to give expert evidence in the famous Selden patent case. It was in 1878 that Clerk developed his first engine which did not infringe on the Otto patent. Otto developed a four-cycle engine, Clerk developed what is known to-day as the two-cycle engine. Otto had an explosion every other revolution of the crankshaft, Clerk had an explosion every revolution of the crankshaft. Thus we find Otto and Clerk the two names that stand for the two broad types of explosion engines, and even to-day the four-cycle engine is frequently referred to as the Otto cycle, and the two-cycle engine, now in very little use, as the Clerk cycle.

Clerk's engine, Fig. 1, used two cylinders, one a working cylinder C, in which the piston operated, and the other a pumping cylinder P, which was used to force a charge of explosive mixture into the working cylinder. The explosive mixture entered through a positively-controlled valve in the head of the cylinder, which was given a conical or hemispherical construction.

The Modus Operandi

The modus operandi of Clerk's engine was similar to that of the two-cycle design of later years. At the lower end of the stroke the piston uncovered an opening X through which the exhaust escaped. In the head was a rotary, slide, or other form of valve, correctly timed to admit the fresh charge from the pumping cylinder. He used a conventional type of connecting-rod used by Otto and invented by Gilles.

After Clerk started the two-cycle movement there was much general activity in the development of two-cycle engines during the life of the Otto patent which restricted the use of the four-cycle principle. Some of the keenest inventors took up the two-cycle principle because it furnished an explosion for every crankshaft revolution which was considered a more efficient type than the four-cycle Otto. Some of the other names of early inventors in the two-cycle field were Day, Robson, Stockport and others. Practically all of them employed the same mechanical arrangements for regulating the intake and the exhaust. All of them did not make use of the pumping cylinder to inject the mixture. Some used what has come to be known as the differential piston in which the piston itself served as a pump. Others used the pressure in the crankcase and took the mixture in through the crankcase so that the down-stroke of the piston served to force it into the combustion chamber.

Daimler's Compound Engine

It is not surprising that after the development of the four-cycle and two-cycle engines so close together, Otto and Clerk, that other methods of getting greater efficiency from explosion engines would be developed. Thus we find in 1879 that Gotlieb W. Daimler of Deutz-on-Rhine, Germany, and later founder of Daimler Motoren Gesellschaft, the home of the German Mercedes car, patented a compound explosion engine with the hope of getting higher

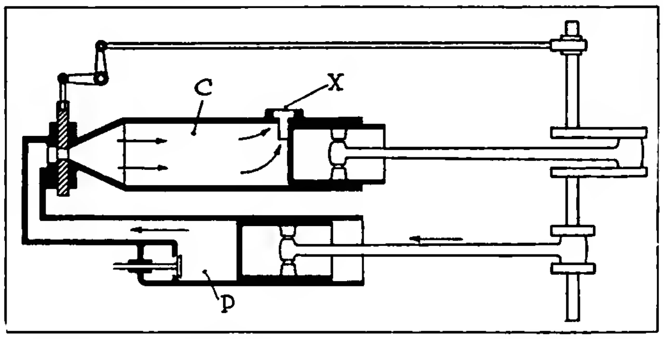


Fig. 1—Clerk's two-cylinder, two-cycle engine of 1878, which comprised a working cylinder C, in which the piston operated, and the pumping cylinder P which was used to force a charge of explosive mixture into the working cylinder. The mixture entered through a positively-controlled valve in the head of the cylinder, which was given a conical or hemispherical construction

efficiency than was obtained in the Otto type. Many to-day remember the compound explosion engine which was manufactured in this country for many years, the car being known as the Compound.

Daimler's patent on the Compound engine, dated Dec. 9, 1879, shows a design of three-cylinder engine, the cylinders arranged parallel. The two end cylinders were explosion types which received the explosive mixture and in which it was ignited. The middle cylinder was a low-pressure one, and in which no explosion occurred, but in which the expansion of the gases from the end cylinders was utilized to drive the piston downward and thus get more use from the explosion and increase the efficiency. The cycle of operations is thus described by Daimler:

"There occurs during each revolution of the crankshaft two impulses, the one being from the two high-pressure cylinders and the other from the low-pressure cylinder. The passage of the gaseous products from the high-pressure cylinders to the low-pressure cylinder can commence before the pistons and the former arrive at the extreme end of the out stroke; but the low pressure piston must at the same time have just arrived at the extreme end of its end stroke."

Not Commercially Practical

Daimler's patent contains a symptom of doubt as to the practicability of the low-pressure cylinder in that the patent sets forth that the two high-pressure cylinders can be used without the low pressure one, in which case their products of combustion are discharged direct into the atmosphere. This form of motor showed an increase of 15 per cent in efficiency but never came into successful use due to the added weight and the complications it required.

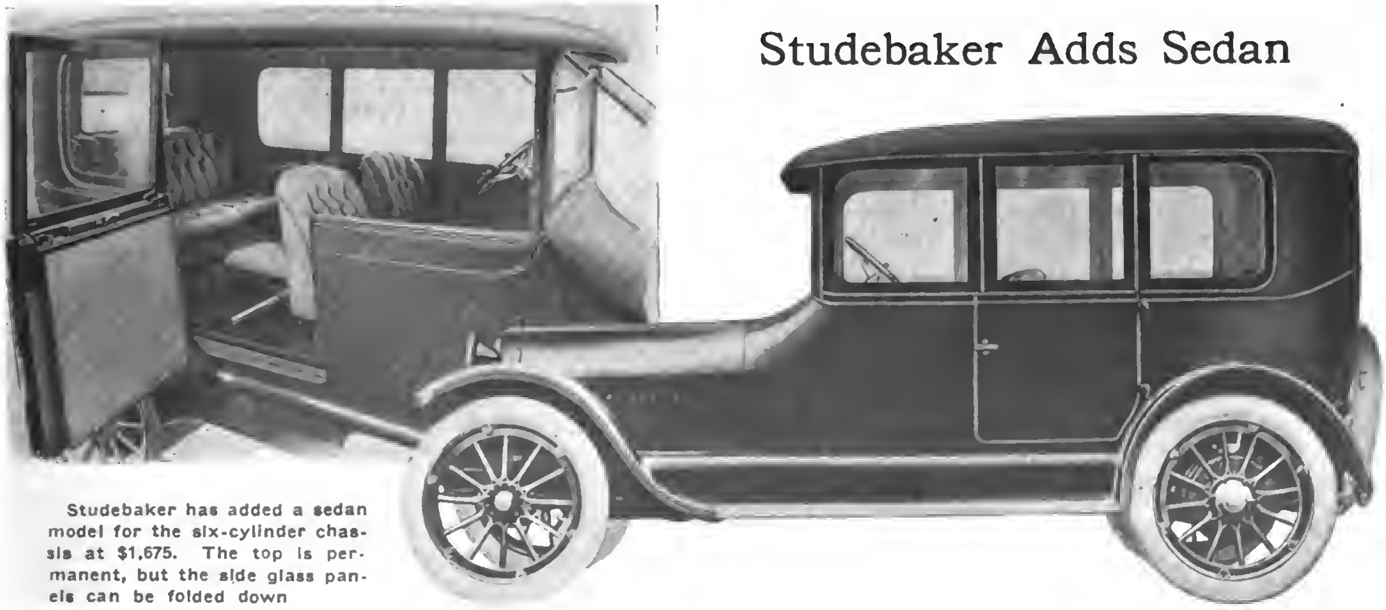
Selden Enters the Field

In America at this same time matters were developing that later were of great moment in the automobile industry. It was in May, 1879, that George B. Selden filed his application on his patent relating to an explosion engine and also an automobile which later brought about the celebrated Selden suit which was defeated by Henry Ford and others five years ago. It was the activity of Otto, Clerk, Gilles, Holton, Brayton and others that brought the importance of the explosion engine to the attention of Selden, who was a patent attorney. Selden's engine was built on the Brayton air-tank design and not on the Otto four-cycle, or the Clerk two-cycle principle.

Engine of the Brayton Type

With his brother, A. R. Selden, he had discussed horseless carriages while visiting the Centennial Exposition in 1876 at Philadelphia, at which place he saw the Brayton engine and talked with Brayton. In the latter part of 1877, he did some work on a small brass model engine and in the spring of 1878, got out drawings and had a crankshaft forged for his three-cylinder engine of the Brayton type. He seems to have recognized the necessity of light weight and compact arrangement and as compared with Brayton engines built for stationary or boat use, his conception was superior, even though in many respects faulty. He made no provision for waterjackets but claimed to cool by introducing water into the crankcase, a method that when accidentally tried by modern gas engine users has customarily caused trouble. He applied for his patent in May, 1879, and slowly fought it through the Patent Office, taking frequently the permitted two years between actions which was his legal right. When the case was finally ready for issue, he prepared a smooth copy for the office which contained some changes not properly belonging therein but which apparently passed unnoticed by the office. His patent was issued in November, 1895, after the industry had developed to a practical point without his aid, as demonstrated by the Chicago contest of that month.

Studebaker Adds Sedan



Studebaker has added a sedan model for the six-cylinder chassis at $1,675. The top is permanent, but the side glass panels can be folded down

The Rostrum

Suggests Screening Air Intake

EDITOR THE AUTOMOBILE:—I take the liberty of writing you on a subject which seems to have escaped the majority of manufacturers of carbureters. I will ask you a question and give you one answer. Although I know there may be several answers to the question, I think mine deserves consideration.

Where do scored cylinders originate?

Answer—Through the air intake of the carbureter through which is drawn all the dust and dirt which comes within the radius of the suction, and I think you will agree with me that a considerable amount of dust and dirt accumulates around the engine. I think it would be a good thing if a proper screen were provided on the air intake, to prevent the dirt from being drawn into the cylinders and made easily accessible for cleaning purposes.

Montreal, Que. J. B.

Inadvisable to Enlarge Valves

Editor THE AUTOMOBILE:—I wish to increase my compression to 100 lb. How much can I plane off my cylinder head and how much will I have to raise my pistons?

2—How much can I enlarge my valves without coming too close to the waterjacket?

Chicago, Ill. W. S.

—It is impossible to tell you how much to reduce the volume of your combustion chamber to reach 100 lb. compression without knowing what the original volume is or how much the bore of the cylinder is. The method of procedure, however, which you can follow to work out the problem for yourself is as follows: Multiply the compression pressure by the volume of your present combustion chamber and divide it by 100 to secure the total volume of the new combustion chamber.

For example: If your present compression is 70 lb. and the volume of the combustion chamber is 20 cu. in. to have a compression of 100 lb. the volume of the combustion space would have to be $\frac{70 \times 20}{100}$ or 14 cu. in.

2—It is inadvisable to enlarge them at all.

Timing Pope-Hartford for Speed

Editor THE AUTOMOBILE:—We have a model T 1909 Pope-Hartford motor which we have rebuilt. The cylinders have been rebored from 4 5/16 to 4⅝ and it has 5⅛ stroke with racing pistons. It is equipped with a Bosch magneto. Will you please tell us how to time the cams and ignition so as to get the most speed and power?

Oneonta, N. Y. ONEONTA GARAGE CO.

—To work out a racing timing is a matter of experiment as the timing not only depends on the general design of the engine itself but also on the conditions that obtain in the manifolds. It is assumed from your questions that it is your idea to have this engine operating at high speeds and in that case an early exhaust opening and a late intake closure coupled with high compression will probably be the scheme under which you will work. It might be well to start with an intake opening at top center and intake closure at about 20 deg. past lower center. Exhaust opening 45 deg. before bottom center and closing 10 deg. after top center. The ignition should be carried as far in advance as possible without having a knock. This is done by advancing the magneto one tooth on the timing gears so that your advance is carried forward as far as possible.

Diagrams of Electric Systems

Editor THE AUTOMOBILE:—Kindly publish diagrams of the North East systems for former Metz and Marmon four and six cars?

2—Are the Jesco, Adlake, and Rushmore systems being made this year?

3—Would like to see the circuit diagrams of the Owen Magnetic car and its transmission.

4—How should roller clutches be lubricated? Is any one way of lubrication better than another?

5—How many elements enter into the function of spark advance? Lag of current, combustion, etc.? Theoretically, is the position of piston exactly the same at low speeds as at high speeds after allowing for lag of current, process of combustion, etc., and is this position at or near top of center?

Weymouth, Mass. H. R. B.

—The diagrams you request of the North East systems for Metz and Marmon cars are shown in Fig. 1.

2—Yes.

3—The circuits of the Owen Magnetic car are as follows:

A—Charging position means, starting and lighting battery being charged by generator through engine running. Car stationary.

B—Starting, generator connected in series with starting and lighting battery, generator acting as a motor.

C—Neutral, car stationary with engine running. When car is coasting motor becomes an electric brake controlling car to maximum 15 m.p.h.

D—First speed. Generator and motor in series resistance shunt across generator field.

E—Second speed. Generator and motor in series. No resistance.

F—Third, fourth and fifth speed. Generator and motor in series resistance shunted across motor field.

G—Sixth speed. Generator short circuited on itself. Motor independent from generator circuits acts as a generator for charging battery.

4—The clutch must be lubricated once every week with high grade engine oil injected in the oil openings.

5—Yes. The nearer explosion occurs to top dead center position of the piston the better. It is only to allow for the relative lag that spark is advanced at higher speed.

Fuel Leak Cuts Lubricant

Editor THE AUTOMOBILE:—The discovery of a new condition in the oiling system of gasoline motors we believe is of sufficient importance to warn all users of automobiles to-day, to be on the lookout for this trouble. The existence of this condition, after careful study, has been determined to be caused by condensation of a part of the gasoline which will not explode when the motor is cold or immediately after having been started on a cold morning.

The present low gasoline contains a large amount of kerosene and less volatile oils. This passing into the motor while it is cold, passes the rings and the pistons and apparently condenses and mixes with the oil in the crankcase. Such a condition will naturally thin down the oil until it lacks all of its lubricating qualities, and if this condition is allowed to continue it will eventually ruin the motor. This is particularly noticeable in motors where the drivers are in the habit of using them for a few miles at a time, and is especially noticed in small towns in the country where it is a short distance to and from the various places of business, when the motor never gets hot enough to assist in evaporating the heavy gasoline procurable at the present time.

Oil Becomes Very Thin

The first symptom of this condition is the apparent economy of oil at the oil level, which remains at a standstill or shows a tendency to rise. In some cases it is necessary to drain the oil from time to time to keep the oil level from causing the motor to smoke. It will be found in draining this oil that it is very thin and in some places equivalent to kerosene.

Careful attention and the frequent draining of oil anywhere from 500 to 1000 miles, and replacing with fresh oil during cold weather is the only thing that will guarantee the user against an injured motor from this cause. The writer has been in the automobile business for the past fourteen years and has never known this condition to exist such as it is now, and believes that it is a public benefit to warn all motorists to be on the lookout for this trouble, which is so easily avoided.

Numerous complaints of fouled motors, even though they have been used but a few hundred miles, have come to my attention, motors which before this condition had arrived had never given any trouble in the accumulation of excessive carbon in the combustion chamber, and we have found this condition to exist in motors of practically every type.

Changing Oil in Vain

The average garage man and the average motorist immediately blames the oil. Then he tries another brand of oil and it does the same, and he shifts again and divides the responsibility between the oil and the car until the cold weather is over and things right themselves.

The reason for this I shall not pretend to determine. Possibly in the mad effort to make three gallons grow where before there was but one, may be the answer. Apparently the lower distillates are so broken up that it all passes for gasoline long enough to be sold as such; but in the engine on a cold morning, you may just as well try burning a mixture of gasoline and kerosene.

Anyway, watch your oil. Drain a half pint of oil out of the bottom of your crankcase and see for yourself.

ANDREW AUBLE, Pres. Akron Auto Garage Co.
Akron, Ohio.

Correct Timing of Chandler

Editor THE AUTOMOBILE:—What is the timing of a Chandler sixteen?

2—What are the meanings of the markings on the flywheel of the Chandler sixteen?

3—What is the price of the Landis shock absorber as illustrated in THE AUTOMOBILE, Chicago show number, and also the address of the manufacturer?

4—What is meant by a cam which is variable at different speeds? What is the profile of such a one like?

Malone, N. Y. F. J. D.

—The firing order of the Chandler motor is 1-5-3-6-2-4. The inlet valves are 2-4-6-8-10-12; the exhaust valves are 1-3-5-7-9-11. The exhaust valve closes 1⅝ in. past dead

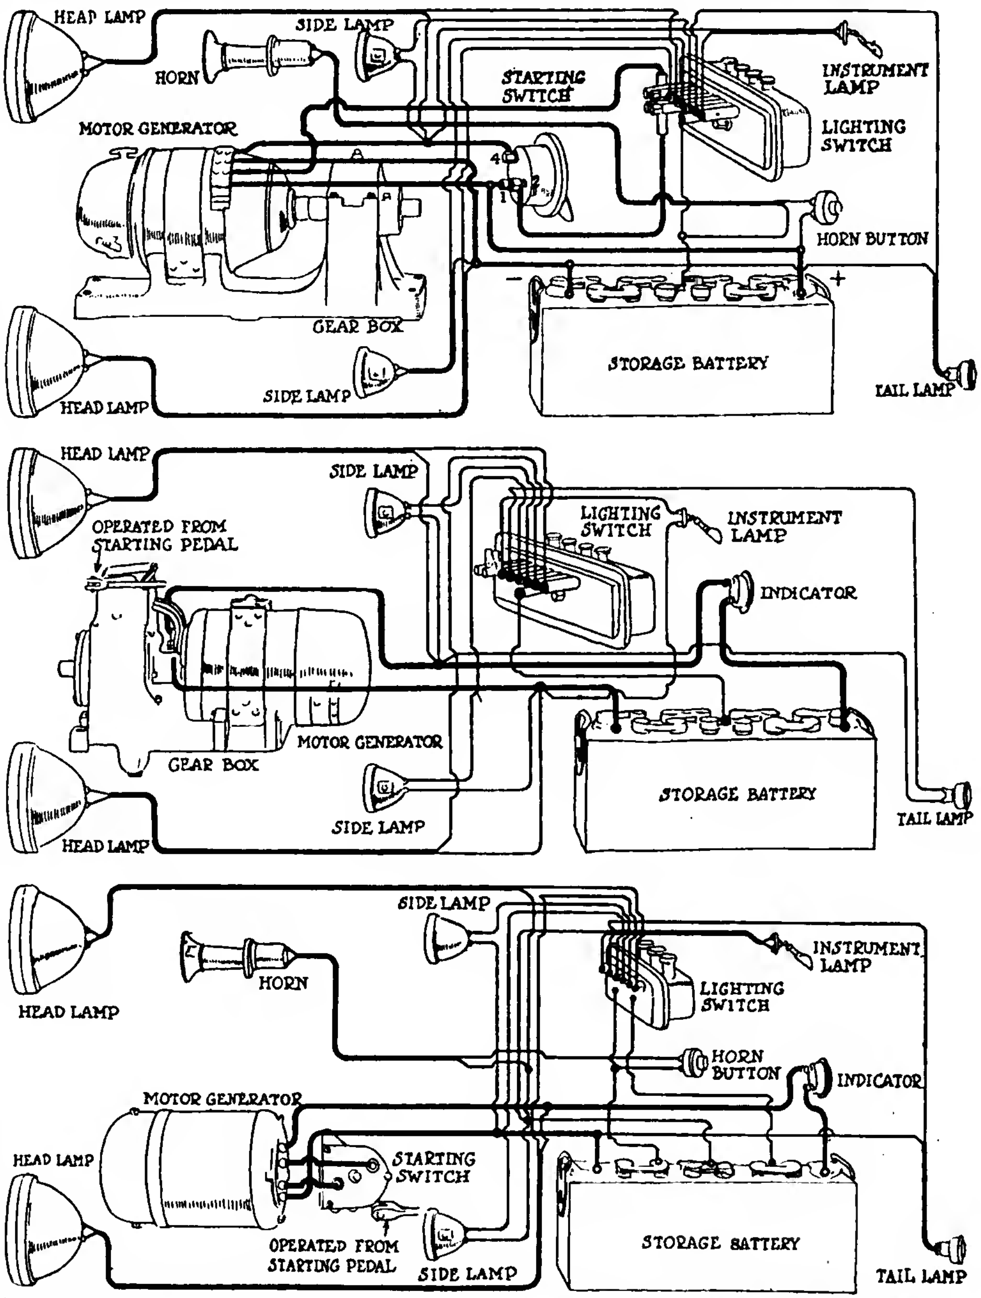


Fig. 1—Wiring diagrams of the North East electric systems used on the Metz and Marmon cars. Top—Old four-cylinder Marmon. Center—Former Marmon six. Bottom—1914 Metz

center on the suction stroke. The inlet valve opens 1⅞ in. past dead center on the suction stroke.

2—The flywheel is marked, as is the top of the flywheel housing at the filler plug. When the marks on the flywheel and case are opposite one another, No. 1 piston is at top center. With the valves closed the clearance between the valve plungers and valve stems should be 0.004 in. and for best results should be set when motor is hot.

3—The price of the Landis shock absorber is $30 a pair, or $60 for a set of four. This shock absorber is manufactured by the Landis Engineering & Mfg. Co., Waynesboro, Pa.

4—Presumably you mean a cam which can be varied by manual shifting. Such a cam has one profile at one end and another at the other, being made perhaps three or four times as wide as the roller which it operates. The profile changes slowly so that by sliding the camshaft the different portions of the cam can be brought underneath the roller and so different valve timings are obtained.

Lost Motion in Steering Gear

Editor THE AUTOMOBILE:—The steering wheel of my Chevrolet Royal Mail has about 3 in. of lost motion, and there is no reason for this, as the car is a new machine and has been run only about 2000 miles.

2—Is it practical to mix gasoline and kerosene, and burn same in a Chevrolet?

3—What are the advantages and what proportion will give the best results?

Back Bay, Va. J. L. G.

—The best way to take up the lost motion would be to remove the Pitman arm, revolve the gears one-half way around to a new position, as there are no provisions made on this steering gear for an eccentric adjustment, as is found on some types of steering gears. Again this lost motion might be helped some by adjusting the adjusting nut, which is found at the upper end of the steering gear housing to its furthest position in, without binding. This adjustment is for the up and down movement of the steering column, which would have a great deal to do with the lost motion of the wheel.

2—We would not advise mixing kerosene and gasoline, as the carbureter furnished is a strictly gasoline type, and with the low grade of gasoline now being produced with a mixture of kerosene would certainly cause a lot of carbon deposits. This is a trouble that we all like to eliminate, if possible, as it takes a motor expert to disassemble the overhead valve construction and remove the head in order to clean out this carbon which has deposited.

3—These proportions can only be settled by experiment.

Cleaning Fluid for Motor Parts

Editor THE AUTOMOBILE:—Please give me information regarding the potash kettle for cleaning motor parts on dismantling a motor for machine shop use and the proper mixture for use in the kettle. I am told sal-soda will do the same thing. I tried it without much success and it turned aluminum black. There is a demand for a cleaning mixture other than gasoline.

Harvey, N. D. R. M.

—The cleaning fluid which you desire will naturally depend upon the metal to be cleaned. Since you mention aluminum, it is probable that the information wanted covers aluminum cleaning, and a formula for making this fluid is simply a solution of 30 grams of borax in 1 liter of water containing a few drops of ammonia water. To remove discoloration use a solution of one heaping teaspoonful of oxalic acid crystals to one gallon of warm water. Leave the part standing in this solution over night and then clean it thoroughly with water.

A strong soda solution for cleaning grease from machinery and metal parts can be made by taking 10 to 15 grams of caustic soda or 100 grams of soda for each leader of water. This solution should be applied boiling hot and the parts, if not too large, should be dipped into the solution. All that has to be done after this is simply rinse and dry the parts thoroughly.

Hydrometer vs. Voltmeter

Editor THE AUTOMOBILE:—I would like to have you answer through your columns whether it is more accurate to use a hydrometer syringe or a voltmeter to get the results of the life in a storage battery. In the garage where I store and in a number of battery service stations I find that the majority use the hydrometer for testing and will say that the battery is all right. I have been troubled with my starter and the service men say that my battery is at fault, so I have taken the battery to a number of stations but they can find nothing the matter with it. An electrical man I was talking to told me to put on a voltmeter when I put the starter on. I tried this and found that the voltage dropped to about 4½ and stayed there for a few minutes and then gradually came back to the 6½ volts. Can you tell me the reason for this and also to satisfy some of my friends' curiosity as to which is the most reliable for testing the real juice in a storage battery? J. C. W.

Detroit, Mich.

—The hydrometer will tell you one thing and the voltmeter another in examining the condition of a battery. The hydrometer tells you the specific gravity of the electrolyte which must be within certain limits in order for the battery to function properly. If a hydrometer shows between 1.275 and 1.3 when the battery is fully charged the electrolyte is in proper condition. However, it is quite possible for the electrolyte to be in good condition and the battery to show a low voltage on the meter because the plates may be broken down or some other internal trouble not giving the full voltage.

Regarding the particular trouble you mention in which you applied a voltmeter and found that the voltage went to 4½ and stayed there a few minutes and then gradually came back to 6½, it looks as if the trouble were more in the voltmeter than in the battery because the potential would not increase by putting a voltmeter across the terminals. A sticking voltmeter hand was probably the cause of this apparent contradiction.

Pressure Required to Close Brakes

Editor THE AUTOMOBILE:—What is the approximate pull in pounds necessary to operate the service and emergency brakes, direct without any levers, on a medium weight touring car? Also the difference in the perimeter of the two brakes when expanded and contracted and vice versa, or otherwise the brake displacement in fully applying the brakes.

Springfield, Mass. C. M. E.

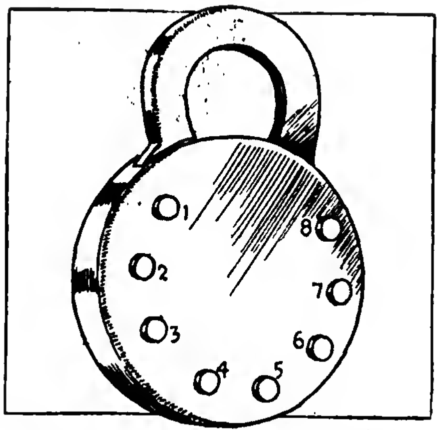
—This varies through such a range that it is impossible to give any definite figures. It is also difficult to determine whether you mean that the brake is locked on the wheel or whether just applied gently. It may be stated, however, that an application pressure of 20 lb. should firmly close the brakes.

The difference in perimeter of the two brakes when expanded and contracted and vice versa is simply the difference between the internal and external diameters of the brake drum. Since you do not mention the size drum you refer to it is again impossible to give you a definite figure, but taking a standard 14-in. drum external diameter having a thickness of ¼ in., the difference in diameter between the inner and outer circle would be ½ in. and the difference in circumference would be one-half of 3.1416 or 1.57 in.

ACCESSORIES

No-Key Auto Lock

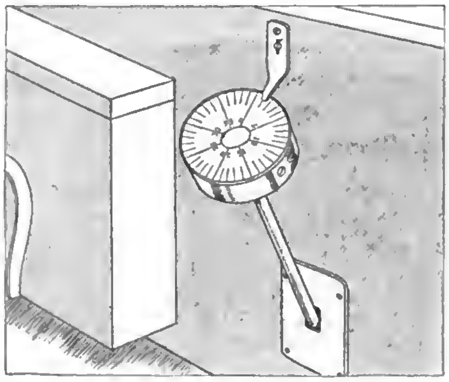
As its name implies, this lock does not require the use of a key, being constructed on the combination principle so that a gentle pressure on certain of the eight buttons shown in the illustration as called for by the combination of each particular lock opens the hasp. There are 40,000 combinations possible so that no two are alike. With this lock there is no danger of a thief picking it open, no trouble or expense due to the loss or duplication of keys, no trouble in opening it in the dark. The combination may be changed as often as desired and there is no danger of the lock getting out of order. Some of the buttons push down and some up and the lock may easily be operated with one hand. It is made of brass and bronze and is consequently very durable. There is no iron or steel about the lock to rust and impair its operation. The locks are useful for protecting garages, cars, toolboxes, spare tires, and all sorts of general purposes. Packed in an individual carton, one lock weighs 5¼ oz. Price, $1.50—Manufacturer, American Keyless Lock Co., Chicago, Ill.; Kapp Specialty Sales Co., New York City, distributor.



No-Key Lock for automobile use. It is a combination type using buttons

Schoener Carbureter Adjuster

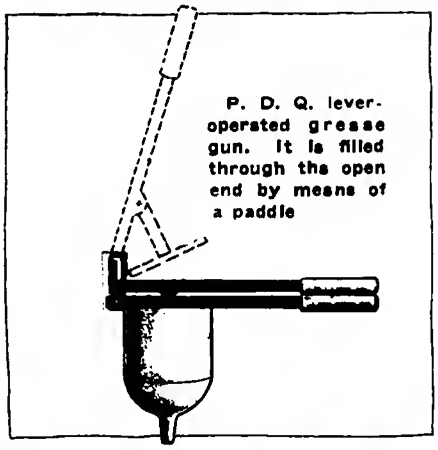
This adjustment for the Ford carbureter is connected by a rod to a dial on the dashboard. The dial is graduated and the graduations are numbered so that when the mixture is changed it can always be brought back to the original position. The device sells for 50 cents.—Schoener Mfg. Co., St. Cloud, Minn.



Schoener carbureter adjuster for Fords

P. D. Q. Grease Gun

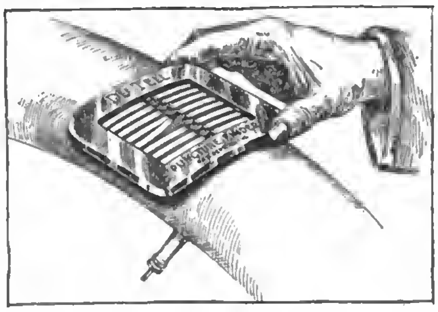
The barrel of this gun is of large diameter and has a conical end and tapered nozzle. The plunger is hinged to a handle which is jointed to swing on a link attached to the top of the gun, and a second handle is attached to the barrel. The gun is filled through the open end by means of a paddle, and the process of expelling the grease is like squeezing a lemon. The gun is quickly loaded and quickly emptied; the large open barrel makes it a simple matter to get in a full charge without smearing grease on the outside. Price, $2.50.—Star Brass Works Co., Kansas City, Mo.



P. D. Q. lever-operated grease gun. It is filled through the open end by means of a paddle

Du-Tell Puncture Finder

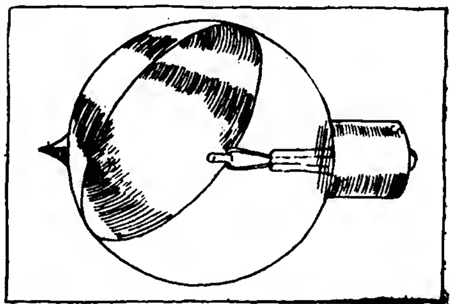
This is a light metal casing, not much larger than a good-sized cigarette-case, with a transparent window on one side and open on the other, contains a number of strips of very thin cork, arranged in two rows; the strips are free to move to a limited extent. The device is used by passing the open side over the punctured tube, close to it. When the escaping air impinges on the cork strips they are made to move, instantly locating the hole. The cork will move under a stream of air that cannot be felt by the wet hand. The device sells for 50 cents.—J. W. Anderson, New York City.



Du-Tell puncture locating device

Glargon Electric Bulb

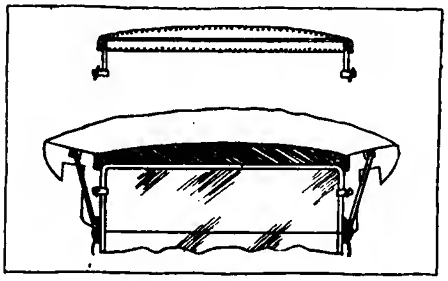
The feature of this bulb is that about one-half of the bulb surface is silvered so that the rays are reflected and thus prevent glare; no rays leave the headlight at an angle above the horizontal.—Greenwood Mfg. Co., East Templeton, Mass.



Glargon non-blinding lam

Limousette for Fords

This attachment is placed on the windshield for the purpose of closing the space between it and the top, thus excluding cold and rain. It lists at $1.50—Lion Buggy Co., Cincinnati, Ohio.



Limousette attachment for Fords

Re-Ac Auto Heater

A hot air car heater has recently been put on the market under the name of the Re-Ac. It is a simple device consisting of a stove for the exhaust pipe, a register permitting a flow of hot air into the car, a hose connecting the tube and a valve for regulating the amount of heat flow.

The hot air stove is readily clamped in position on the exhaust pipe and the register is mounted flush with the floorboards. The valve can be pushed by the toe to any degree of opening desired. The device sells for $10 complete.—The Re-Ac Co., Newcastle, Pa.

Ever-Ready Polish

The maker states that this metal polish is suitable for all finished metal surfaces, hard or soft, that it leaves no sediment, is non-greasy and requires little rubbing. It is put up in cans in the form of a cream.

The Ever-Ready carbon remover, another product, is put up in cans, each can containing sufficient liquid to decarbonize three average motors. The makers point to the fact that it is put up in sheet-iron cans, tinned, as proof of its harmlessness to iron. The polish sells for 35 cents per can and the carbon remover for $2.50 per can.—Every-Ready Mfg. Co., St. Louis, Mo.

Buckbee Self-Adjusting Bearing

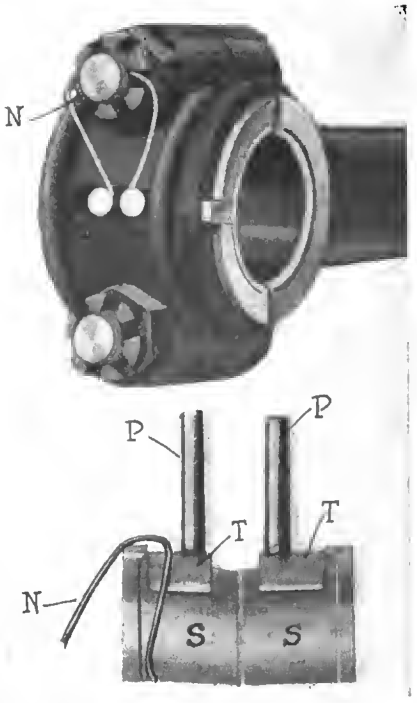
Means for automatically taking up wear are provided in the Buckbee Self-Adjusting bearing for crankshafts and connecting-rod big ends. It is particularly adapted to the connecting-rods, and utilizes the principle of contracting on the shaft as wear occurs.

One of the illustrations shows a connecting-rod fitted with this new type of plain bearing, while the other gives the details of how the outer surface of the cap bushing is inclined and fitted with wedge-shaped segments, the combination acting to automatically set up the bushing to compensate for wear.

The result is accomplished by forming the bushing of two halves, each half being slightly less than one-half the diameter of the shaft, so that they are spaced slightly apart when in place on the shaft. This is to allow for the automatic take-up as the wear occurs.

The part of the bushing carried by the cap member is provided with two cone-shaped surfaces disposed at opposite angles, as shown at *S*. Fitting these surfaces and also the inner surface of the cap member are two similar segments *T* wedge-shaped in cross section and each fitted with a pin *P*. These pins extend through a slot in the cap. A spring *N* attached in some way to the rod end is so looped that one end engages each pin and thus tends to force the wedges up the inclined faces of the bushing. This movement of the wedges forces the cap part of the bushing toward the other part and thus takes up any wear.

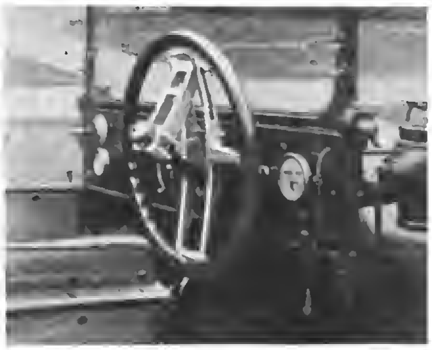
At each end the bushings are flanged to prevent any longitudinal movement in the box, and rotation is prevented by a pin in the usual way. This special type of bearing can obviously be attached to any engine having plain bearings, with very little trouble. Practically the only mechanical change is the cutting of a slot in the bearing cap.—Self-Adjusting Bearing Co., Detroit, Mich.



Buckbee self-adjusting bearing. Above—Fitted to a rod end. Below—Cap bushing

Clear-Room Steering Wheel

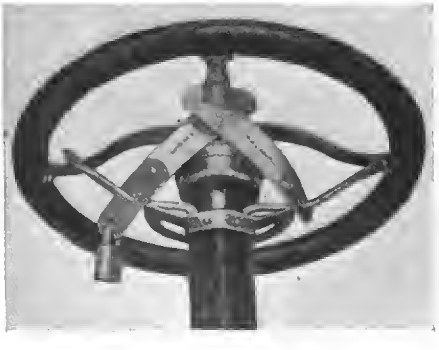
The driver has plenty of room to get in and out of his seat when this wheel is folded; a lock is provided which holds the wheel in either position. Model A is designed for cars with the spark and throttle levers under the steering wheel, and Model B is for cars with the levers over the wheel. Price, Model A, for Fords, 16 in., plain rim, ebony finish, $5.75; 17 in., for Fords, corrugated rim, walnut finish, $6; 17-in., standard type, corrugated rim, walnut finish, $6.50. Model B, corrugated rim, walnut finish, 17 in., $9; 18 in., corrugated rim, walnut finish, $9.50.—Vincent Clear-Room Steering Wheel Co., Detroit, Mich.



Clear-Room folding steering wheel

Bulldog Lever Lock

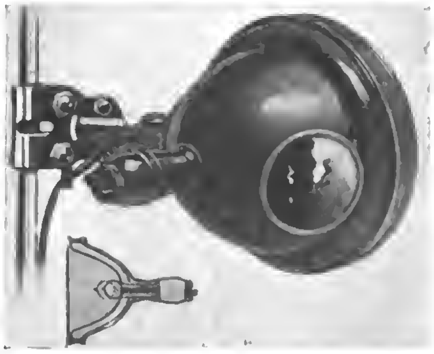
This lock for Fords consists of a set of jointed steel arms which hold the steering wheel, the throttle and the spark lever rigidly in one position when locked. A jaw is formed which grips one spoke of the wheel, while the arms extend to the two levers and are held by a padlock which is supplied with the device. Price, $1.—Koehler Mfg. Co., St. Louis, Mo.



Koehler's Bulldog lock for Fords

Old Sol Spotlight

This light is for reading road signs at night, etc., and is clamped to the side of the windshield within easy reach of the driver. It is supported on a universal joint which allows it to move in any direction. The universal is constructed so that it will not rattle. There is an on and off control on the end of the handle which is at the back of the lamp, so that the light may be used with greatest ease. A focusing device is located just forward of the control switch, where it is ready for instant manipulation. There is a mirror on the back for daytime use which shows what is behind. All models have silver-plated reflectors, 6-volt and 15-c.p. bulbs. The lamps are enameled black. Price, $4.50 for 6 in., $6 for 7 in., and $7 for same light, including pilot light. Tungsten bulbs, 25 cents extra.—Buckeye Motor & Cycle Co., Akron, Ohio.



Old Sol spotlight with mirror

Auto-Lac Top Dressing

This is a black liquid for top dressing and lining dye. It is applicable to all kinds of top fabric and will restore the silk luster and dull original mohair finish to the lining. The preparation sells for $4.50 per gallon can and $1.25 per quart can.—Auto Top Co., Portland, Ore.

Smooth-on Radiator Cement

Leaky radiators are quickly repaired by this cement. The contents of the can will mend up a radiator having a capacity of 4 gal. of water. The can of cement is mixed with sufficient water to form a thin paste and is poured into the radiator while the motor is running; the motor must run until the water is well heated before putting in the cement. The motor is allowed to run until the leak stops, when the water is drained out and the radiator allowed to stand for a short time before refilling with fresh water. If the leak is a bad one the cement is kept in the radiator for a day before draining it off. Price per can, 50 cents.—Smooth-on Mfg. Co., Jersey City, N. J.

Used Car Shows

THE thin edge of the wedge is just being entered in the solution of the used-car situation. A year ago the publication of the used-car market reports quoting actual sale prices of used cars started a movement that has gained much headway since then, the Chicago dealers fathering the movement. This spring another wedge is being entered in the used-car problem, namely, staging spring shows for used cars. One or two of these used-car shows have already been held, and now Chicago is contemplating holding one in May. The working out of these shows will be watched with particular interest, and it is hoped that by this means many of the used cars that have been reposing on upper floor storage spaces and in storage warehouses will be brought to the light of day again and perhaps pushed into the outer world. Much money has been tied up in used cars that have remained stagnant in some cases for many months, and often for more than a year. There should be no better season than the present to properly present these used cars to the public. Heretofore the used car has been considered a millstone. It should not be so. The used-car phase of the business is as legitimate as the new-car one. Chicago and other associations are to be congratulated on bringing up-to-date merchandising atmosphere into the used-car field.

Thermal Efficiency

FOR years past engineers of the older school, accustomed to the use of large engines where the work obtained from every pound of fuel has to be checked and rechecked, have regarded the automobile with some surprise. From the viewpoint of the engine builder who has to show so many horsepower hours per ton of fuel or lose his business, the automobile appears an utterly uncommercial machine.

The reason for this apparent disregard for the fuel efficiency of self-propelled vehicles has been that it has taken years of development to combine the requisite power with the desirable weight. Fuel cost has been so small a proportion of the total maintenance that weight and power became considerations of far greater importance. We have been wasteful of fuel in order to obtain other advantages gained by a rather prodigal expenditure of gasoline.

The use of a cheaper fuel has been an ideal; and it is a curiously happy coincidence that engines designed to give a better thermal efficiency with gasoline are, in general, much more adaptable to the use of kerosene, so in developing a kerosene engine it is more than probable that an engine of better efficiency will be discovered.

Thinking Electrically

IT is essential to-day to think electrically. This is particularly true with garagemen, with those operating machine shops and all other forms of repair depots where diseased electric starting, lighting and ignition systems are repaired. A few years ago, in diagnosing troubles in the automobile, it was primarily essential to think mechanically—that is, to visualize the mechanics of the machine. To-day we have to go a step further and, in addition to visualizing the mechanical systems of the car, also visualize the electrical systems. This latter stage means ability to think electrically.

Thinking electrically presupposes a clear conception of the elementary or first principles of electricity. It is impossible to think electrically without such knowledge. You cannot diagnose electrical troubles unless you know the alphabet of electricity. Perhaps one of the first letters in the electrical alphabet is the circle, the circuit as termed in electrical parlance. Electrical thinking must operate in the circle, starting at a point and coming back to that point. The physical path traveled may not be circular; it may be rectangular—in fact, everything except circular; yet the circular concept is there—you start at a point and you must come back to that point. There must be a complete physical path. That path cannot be broken in a single place without trouble. To detect the trouble you must follow the circular concept. It is the first stage in thinking electrically.

THE AUTOMOBILE starts this week a series on electric units in the car. This series includes an analysis of such systems. It takes up the ills and diseases that beset and tells how they can be corrected.

Automobile Manufacturers Form Co. To Produce Gasoline at Lower Prices

United Motor Fuel Corp. of Manhattan Will Also Supply Information Regarding Cost of Production—Will Safeguard Stock Against Anyone Securing Control

NEW YORK CITY, April 5—The most important result of the increasing agitation against excessive gasoline prices is the organization of automobile manufacturers into a company for the production of gasoline and also to supply complete cost information on gasoline production with a view to protecting the makers and users of automobiles, motor trucks and other users of the fuel. It is the United Motor Fuel Corp. of Manhattan which was formally incorporated at Albany yesterday with $25,000 capital. The company will distribute its stock throughout the whole country in such a way that it cannot possibly pass into the control of any competitive interest. The capital will eventually be increased from $5,000,000 to $10,000,000.

The directors of the United Motor Fuel Corp. of Manhattan are: S. A. Miles, manager of the New York and Chicago Automobile Shows; J. A. Royall, for many years identified with the production of gasoline; A. L. Prindle, C. H. Mapledoram, a lawyer with offices at 100 Broadway; E. L. Gluck, T. R. V. Fiske, E. W. Stettit, C. H. Adams, C. J. Elias, W. Sterin, A. T. Swords, W. Little, New York; H. Fobes, Ridgewood, N. J.; H. Carter, Plainfield, N. J., and J. C. Barr of Brooklyn.

Offers of Land, etc.

The new company will prospect, produce, act as jobber in crude oil, build refineries and develop a large selling organization. Alfred Reeves, general manager of the National Automobile Chamber of Commerce, Inc., who is in close touch with the promoters, states that they have received numerous offers of oil land, refineries, equipment, etc.

Before any active steps were taken exhaustive reports of the conditions surrounding the oil business were quietly prepared, with the result that the manufacturers evinced their willingness to test the theories advanced by the oil companies concerning the reasons for the high prices now prevailing and the further advances so frequently threatened. It was during the lengthy conferences held within the past few days between representative automobile manufacturers, officers of the N. A. C. C. and men of experience in the oil industry that the plan to form an organization which would produce results in the way of reducing the price of gasoline to the automobile and truck user was decided upon.

The purpose of the new company will be to produce gasoline, kerosene, lubricating oil and other products of petroleum, not necessarily for the purpose of injuring any business at present in operation but to demonstrate that gasoline can be profitably produced and sold at a price lower than that now prevailing.

"This," said Mr. Royall, "we regard as the only real remedy for existing conditions. We shall, at the very least, demonstrate that no further increase is necessary, and so protect the business of the automobile makers and their hundreds of millions of invested capital.

"From 1859, when Drake discovered oil in Pennsylvania, down to the present day, the oil business has been one of constant agitation and concern to people.

"Yet in all these years, with Government, State and other investigations actively concerned in providing a remedy to deal with it, none has been found.

Two Possible Remedies

"So the only remedy to apply is actual Government control, which is neither feasible nor desirable at this time, or the formation of a company owned, managed and operated in the interests of the whole people.

"This corporation, when it is finally launched, will include all interests outside of the oil interests; and in this latter designation I include the so-called 'competitive oil interests,' from which no relief can be expected. They are all founded upon the same selfish interest, and maintain prices rather than provide real competition to the business.

Other Industries Included

"This company," continued Mr. Royall, "will have upon its board of directors a large representation of the automobile and other allied industries, which, despite their hundreds of millions of invested capital, are now wholly without representation in business so vital to their present and future welfare. In addition to its board and managing directors it has been suggested that the company have an advisory board of at least 250 non-resident advisors, elected pro rata according to the population of the various States, who will act without compensation. In applying the remedy it is not the purpose to disturb the great oil industry by resorting to destructive methods of competition, nor to single it out for attack by any other method, but only to create a highly organized competitive company, operating for profit, with the highest ideals of business integrity in all of its dealings with the people and, further, to open the book of knowledge concerning the oil business."

Life Insurance for Makers

Mr. Miles, who has been in consultation with manufacturers and others, stated that in connecting himself with the new company he felt assured of their hearty co-operation. Declaring that the new company will really attempt to provide life insurance for the builders of automobiles, motor trucks, etc., Mr. Miles pointed to the fact that the consumers' cost is now at the rate of $157,248,000 per year more than in August, 1915. Supporting this contention, Mr. Miles pointed out that the production of gasoline last year, as reported by the Department of the Interior, was 41,600,000 barrels of 42 gal. each, or 1,747,200,000 gal. The price has gone up in some places 100 per cent and in few places less than 40 per cent. In twenty of the principal cities of the United States the average price of gasoline in August of last year was 12.46 cents per gallon. The latest reports indicate that the price in the same twenty cities is now 21.56. Calling the increase 9 cents per gallon, the above figure of $157,248,000 increase is obtained.

Perlman Buys Jackson Rim Co.—To Boost Output

NEW YORK CITY, April 5—The Perlman Rim Corp. has purchased the entire capital stock of the Jackson Rim Co., Jackson, Mich., and the transfer of the property will take place on April 10, after which date it will be called the Perlman Rim Corp. Jackson plant. The Perlman corporation will erect additional factory buildings and will increase the equipment to such an extent that within three months the plant will be producing 4000 sets of demountable rims per day, or at the rate of over 1,000,000 sets a year.

The Perlman organization is also concluding contracts with other rim manufacturers for quantities of rims which will be ample to meet the requirements of the car manufacturers, so that there should be no delay in production because of lack of demountable rims. Rims are also being made at the Mott Wheel Works, Utica, N. Y., the Perlman corporation controlling the rim plant of the Mott works.

Contract has been closed by the Perlman interests with the Willys-Overland Co., the largest user of demountable rims in the world, for its requirements during the remainder of the season, and contracts with other car manufacturers are being arranged on a satisfactory basis.

Used Car Show for Chicago

Trade Assn. To Hold First Exhibition in Coliseum May 8-15

NEW YORK CITY, April 5—The Chicago Automobile Trade Assn. has gone one step farther in solving the used car situation. On May 8 to 15, it will hold a used car show in the Coliseum in Chicago, sanction for which has just been given by the National Automobile Chamber of Commerce. This is the first used car show that has been staged on a large scale in this country.

E. G. Westlake, Henry Paulman and Edwin Grier compose the show committee. Mr. Westlake, who has been in New York, to-day has requested sanction from the N. A. C. C. and has returned to Chicago, where he is going ahead with the plans of the show.

About eighty dealers will be represented at the exhibition, which will be purely a Chicago affair. These will represent about 95 per cent of the dealers in that territory. According to plans no trucks, accessories or 1916 cars will be on exhibition. All cars that are sold may be taken out at night and other cars put in their places.

A public drawing for space will take place in the near future and the dealers will be charged 25 cents a square foot for space. Each dealer is expected to take 800 sq. ft. of space, thus bringing the charge to $200. This amount, however, is expected to be made up in rebates.

Admission will be either 50 or 25 cents. The dealers will receive their tickets at half rates. The building will be decorated with flags, and will be opened from 10 a. m. to 10 p. m.

Freight Car Situation Improves But Shortage Continues

DETROIT, MICH., April 4—For the first time in several months, automobile traffic managers, railroad officials and others having something to do with the traffic matters in this city, reported a slight improvement in the freight car situation. Some say that this is due to better weather in the East, others claim that the publicity given to the matter of increasing demurrage rates from $1 to $2 has brought about quick action by many consignees and shippers in taking prompt delivery of shipments, thus releasing a large number of freight cars for further use. Still there are others who say that in New York, Boston, Philadelphia and other Eastern cities more actual activity has been shown during the past week in relieving the congested roads, than in many weeks.

Whatever the reasons for the better conditions are, the fact that several railroads have lifted existing embargoes is sufficient evidence that there has been a betterment.

During March, 75 per cent more freight cars entered and left Detroit than during the corresponding month in 1915. It is estimated that fully 40 per cent of all the carloads which left the city contained automobiles or automobile parts. Of the 75 per cent increase, more than 50 per cent is credited to the automobile industry.

Automobile manufacturers are reported to be offering high premiums for regular automobile freight cars.

28,600 Carloads of Automobiles Shipped During March

NEW YORK CITY, April 5—Shipments of automobiles during March, 1916, were the biggest for that month that the automobile industry has ever known, amounting to 28,600, as compared with 17,192 in March, 1915 and 23,809 in February, 1916, the best previous record. Six thousand of these carloads were made in box cars, by taking off the fenders and covering with tarpaulin.

The shortage of freight cars is reported just as bad as ever by the National Automobile Chamber of Commerce, which held its monthly meeting to-day. At this meeting the Chamber voted the indorsement of the action taken by the New York Automobile Dealers' Assn. against examining and licensing all owners of automobiles, believing this measure would fall short of accomplishing what its advocates claimed it would do.

The Chamber also voted that the automobile industry should co-operate with H. E. Coffin, Chairman of the Production and Standardization Committee of the Naval Consulting Board, and with the U. S. Government, on a plan for mobilization of trucks for preparedness.

After the monthly meeting of the directors, the members present met to consider reports of the proceedings in the matter of the United Motor Fuel Corp. The manufacturers gave tangible evidence of enthusiastic co-operation and pledged additional financial support to the preliminary work of the company.

58,329 Fords Built in March

DETROIT, MICH., April 4—In March, the Ford Motor Co., made 58,329 Ford cars. This is 14,450 more than in March, 1915, which was the record thus far for a month's output at the Ford. The total value of this year's March production was $24,176,535. The average daily output was 2243 cars. On March 25, the record for a day's output was established when 2768 cars were completed.

Three Makers Raise Car Prices

Anderson Electric, Chalmers and Pathfinder Announce Price Increases

NEW YORK CITY, April 3—Three more automobile makers announced price increases this week, making a total of eleven which have done so; three have made reductions.

The Chalmers Motor Car Co. has advanced the prices of the three models built on the new 6-30 chassis, effective April 15. The touring car and cabriolet will each be increased $40, making the former $1,090 and the latter $1,440; the price of the roadster will be raised $20 to $1,070. All of these figures are f.o.b. Detroit. The increased cost of materials is responsible for the higher prices.

The Pathfinder Co., Indianapolis, has raised the price of its twelve touring car, $275, effective April 15. The cloverleaf roadster is $425 higher.

The Anderson Electric Car Co., Detroit, is the first among the electric vehicle makers to announce an increase in the price of its cars. This increase will be $100 for each of the five models made by the company and will go into effect April 8.

A summary of the price changes since Jan. 1, 1916, follows:

INCREASE

Co.	New	Old
Chalmers 32B	$1,450	$1,350
35 roadster	1,070	1,050
35 touring	1,090	1,050
35 cabriolet	1,440	1,400
Anderson Electric cabriolet, 3-pass.	2,175	2,075
Brougham, 5-pass., front drive	2,350	2,250
Inclosed type, 4-pass	2,275	2,175
Brougham, 5-pass., rear drive	2,325	2,225
Brougham, 5-pass., double drive.	2,375	2,275
Dort	665	650
Studebaker:		
Roadster four	850	825
7-pass. four	875	845
Landau roadster four	1,150	1,145
3-pass. six	1,060	1,025
7-pass. six.	1,085	1,050
Saxon six	815	785
Marmon:		
5-pass.	2,900	2,700
7-pass.	2,950	2,750
3- and 4-pass	2,950	2,750
Buick six:		
Roadster	985	950
Touring	1,020	985
Empire four	935	895
Scripps-Booth four:		
Roadster	825	775
Stearns-Knight:		
L4 5-pass	1,445	1,395
Eight, touring	2,100	2,050
Pathfinder Twelve:		
Touring	2,750	2,475
Roadster	2,900	2,475
Joliet Tractor:		
Bates Steel Mule	895	865
Avery Tractors:		
5-10 hp.	365	295
12-14 hp.	1,195	1,125
18-36 hp.	1,775	1,680
25-50 hp.	2,190	2,145
40-80 hp.	2,625	2,475

DECREASE

Cole	1,595	1,785
Overland	695	750

Seven Divisions of S. A. E. Standards Committee Report Rapid Progress

Nomenclature, Miscellaneous, Engine and Transmission, Research Discuss Many Subjects—Many Important Topics Scheduled for General Meeting in Cleveland

NEW YORK, April 3—Last week was a busy one for the standardization work of the S. A. E., seven division meetings taking place in New York, Detroit and Buffalo. The main points in the work of the Electrical Equipment division which met on March 28 were dealt with in the last issue of THE AUTOMOBILE, and mention was also made of the proceedings of the nomenclature division. The truly immense task of finding names capable of universal application, for all the parts of a chassis is nearing conclusion, and it is practically certain that a complete dictionary of terms will be ready for presentation to the Society in June. There are now only quite a few portions to be completed, and it is judged that two more meetings of the division will be sufficient. Since active work was started only last summer the progress has been very rapid indeed, for the difficulty of the work is quite great.

Fuel-Economy Test Specification

At the meeting of the Research division held in Buffalo April 1, some eight hours were spent in working out a specification for testing automobiles for fuel economy. This division had previously prepared such a form and presented it to the last meeting of the Society in January, 1916, but it was then voted that the restrictions were insufficiently rigid and the matter was referred back for further consideration.

The idea of this work is to provide full instructions for testing and checking tests so that manufacturers or others can make fuel economy demonstrations on a standard basis, so that the results will be directly comparable. It was felt that the motorist desires to know as closely as possible what his own car may be expected to do rather than what can be done with a car of that make when economy is everything.

Must Be Speedway Test

Thus the division is going to recommend a very rigid test indeed. The specification will be discussed at the next general meeting of the whole standards committee which takes place on April 21, and will then come before the whole society on the summer trip in June. It is possible that the present recommendations may be modified, but there is little doubt that a test carried out along their lines would be conclusive.

After much discussion it was agreed that the test to have any standard value must be made upon a speedway, where conditions vary less than on any road. Next that it was not fair to allow just one speed to be chosen, as that would allow the carbureter to be adjusted for that particular speed. The following schedule is suggested:

M.p.h.	Distance	Time
10	10	1.00
15	10	0.40
20	10	0.30
25	10	0.24
30	10	0.20
40	10	0.15
50	10	0.12
Total	70	2.41

Each run is to be repeated in the opposite direction, that is, two runs at 10 m.p.h. will be made, then two at 15 m.p.h. and so on.

When all the gasoline consumption runs have been made there must be an acceleration test, the results of which must be entered on the test form together with the consumption figures; this being to guard against the use of phenomenally weak mixture.

There are many other restrictions. For instance, it is laid down that the cooling system must be fully operative, meaning that the radiator must be full, that the fan must be running and no blanketing of the radiator will be allowed. Once set, the mixture must not be altered throughout the whole test, including the test for acceleration.

Fuel Tank Arrangement

The division recommends a particular arrangement of fuel tanks for the test, consisting of two special tanks carried on the back of the windshield. Of these one is weighed before the start of each stage of the test and the other is used for intermediate running, an arrangement of two cocks, allowing the switch from one to another to be made instantly. It was decided to recommend weight measurement, as this is so much more simple and accurate than volume measurement. All tests are to be made with gravity feed on a definite head.

There are many other details, directed toward the prevention of evasion of the spirit of the test. The rules are so rigid, in fact, that no false results could be shown as long as the observation and checking were carried out properly.

Electric Units' Mounting

On March 30 the engine and transmission division met in Detroit and opened proceedings by appointing members to serve on a joint sub-committee with representatives already chosen by the electrical equipment division, to discuss the possibility of setting up standards for the mounting of ignition units, generators and starting motors. Next the subject of V-belt proportions was considered and it was reported by W. R. Strickland that, while British practice was already almost standard, there was no sort of agreement among American firms, either automobile manufacturers or belt makers. After a long discussion it was decided to take steps to have a number of tests made to decide the best angle for the pulley groove and the best proportions for belts. The chairman of the standards committee, A. Ludlow Clayden, undertook to try to arrange for a test to commence shortly. Practically every British user has adopted a 28-deg. angle for V-belting, but American types vary from 35 up to 60 deg.

W. T. Fishleigh, chairman of the division, then presented a number of blueprints of engine characteristics prepared, some by manufacturers and some by Professor Fishleigh himself in the laboratories of Michigan University. This division does not expect to make any report to the general meeting in Cleveland on April 21, but meets there April 22.

Curves for Groove Depth

March 31 was spent in active session by the miscellaneous division, which has a great number of subjects before it. The two principal items of the day were agreement upon a drive connection for speedometers, which will be submitted at Cleveland, and a further consideration of piston ring dimensions. The widths of rings for pistons of various diameters had already been decided, and there remained the determination of the proper depths for ring grooves in the piston.

The recorder to the Standards Committee had plotted some curves for groove depth in accordance with a suggested formula, and the latter was modified somewhat so as to increase the depth for small sizes while scarcely affecting that for the larger. On steering wheel sizes, the chairman, J. G. Utz, reported that the only part of a wheel suitable for standardization is the hub or center, where it is bored for attachment to the steering column. It is neither possible nor desirable to attempt to standardize the rim or spokes of the wheel. The following is the list of subjects now before the miscellaneous division in the order of importance:

1. Speedometer drive connections
2. Piston ring groove dimensions
3. Gearshift positions
4. Steering wheel hub dimensions
5. Taper sockets for fender supports
6. Heavy duty rod ends (wider than the existing standard)
7. Fillister, countersunk, round, French and carriage head bolts
8. Length of thread on S.A.E. standard bolts
9. A.S.M.E. pitches for small screws
10. Thread tolerance
11. Lock washer pressure.

Several other suggested subjects were

discussed and a recommendation to the Council passed that these other subjects be left alone for the present.

On April 4 the truck standards division met in New York with the purpose of clearing the slate of a number of small matters. A variety of subjects which had been suggested as suitable for the consideration of this division were discussed and most of them considered too unpromising for present treatment. The trailer hitch which seemed a good subject was found to be too complicated with patent devices. It was decided to postpone action on sections for solid tires in order to see how closely the standards for wheel diameter will be adhered to.

The most important matter now before the division, concerning which investigation is being made is that of control for trucks. European mobilization of motor trucks has shown that the military value of standardized control is incalculable. Gear lever positions ought always to correspond, brakes should have similar locations, throttle levers should always move in the same direction for opening, and so forth.

After several set-backs it now appears that there is hope for the establishment of a rating for solid and pneumatic tires which will help a truck manufacturer to choose the best size of the tire to give the lowest possible cost per mile. Some suggested tables were drawn up and are to be circulated among the tire makers for their consideration and amendment.

Ball Thrust Bearings

April 5 was taken by the ball and roller bearings division for a discussion on the standardization of thrust bearings, which follows naturally upon the work already done with the radial bearings. This work consists of a careful examination of practice and it is hoped to be able to complete it within a comparatively short space of time.

Wertman, of McGraw Tire, Promoted

NEW YORK CITY, April 1—C. E. Wertman, formerly assistant branch manager of the McGraw Tire & Rubber Co., this city, has been promoted to the position of resident manager, succeeding R. F. Hobron. E. E. Cowan has been appointed to the position of sales manager of the New York territory.

Tests on Sylphon Thermostat

WORCESTER, MASS., April 1—Tests made at the Worcester Polytechnic Institute on the Sylphon circulation regulator made by the Fulton Co., Knoxville, Tenn., and used on two prominent multi-cylinder cars have been completed. These tests from reports received would tend to show that the use of the regulator, which incorporates a thermostatic control of a by-pass valve, results in an increased fuel economy.

Variable Cutoff Is Suggested

Hoosier Engineers Discuss Higher Compression and Increased Thermal Efficiency

INDIANAPOLIS, IND., March 31—Increasing the compression and controlling power by variable intake cutoff were discussed as possible means of increasing the thermal efficiency of automobile engines at the meeting of the Indiana section of the Society of Automobile Engineers, held at the Claypool Hotel this evening. This discussion was the result of the statements made by C. E. Sargent, chief engineer Lyons-Atlas Co., in the paper of the evening, Increasing the Thermal Efficiency of Automobile Engines, which appeared in THE AUTOMOBILE for March 30. Mr. Sargent, who has had long experience with the Diesel type of high-compression engine and with gas engines of large sizes, is particularly fitted to discuss the advantages and disadvantages of higher compression than is used in motor car engines.

In his paper Mr. Sargent's remarks were based upon the fact that the average good internal combustion engine has been never much greater than 20 per cent efficient. This means that only one-fifth of the actual power possibilities in the fuel has been turned into useful work in this type of engine. His remarks were directed toward the development of engine design which would decrease some of the 80 per cent heat loss in friction, cooling water, radiation and exhaust. He offered for consideration the idea of varying the cutoff rather than the throttle to produce changes in engine speed and power. By this is meant changing the time at which the inlet valve closes instead of changing the amount of opening of the throttle.

Points Worth Study

It seemed to be the consensus of opinion of the engineers present that the points brought up by Mr. Sargent's paper were worth study from a theoretical standpoint, and embodied more a theory whose results might be worked toward rather than a practical basis for engine design at the present day. Among the engineers who took part in this phase of the discussion were, J. G. Vincent, Packard; Howard Marmon, Nordyke & Marmon; A. P. Brush, Brush Engineering Corp.; John O. Heinze, Heinze Electric Co.; Chester Ricker; Eugene Gruenewald, Moline; Mr. Grimes, National, and R. H. Combs, Prest-O-Lite.

Mr. Heinze stated that the engineers were aiming to maintain the same high compression and develop the same high efficiency of fuel economy at all speeds and at all power production. In other words the ideal is to permit flexibility and power without sacrificing thermal efficiency.

Mr. Sargent explained that the reason for closing the inlet valve late was in the attempt to get all possible fuel efficiency out of the motor, the effort being to make the motor as efficient under low loads as under high loads.

Mr. Heinze mentioned a motor which he developed two years ago arranged so that the time of closing of the intake valve—that is the cutoff—could be varied by having split cams. It was found that by varying the cutoff in this way it was possible to get as high as 19 per cent thermal efficiency, but not maximum power. In order to obtain the maximum power the thermal efficiency had to drop to about 16 per cent, that is, at 28 and 30 hp. the efficiency was 16 and at 25 it was 19.

Chairman F. E. Moscovics mentioned an English engine of several years ago which had a variable cutoff, and also stated that one of the old Wintons had a variable pressure maintained by using an air cylinder which operated in connection with the intake valve.

Chester Ricker explained that that valve was purely automatic, a light spring just sufficient to lift the valve was so connected with a piston in the air cylinder that it increased the air pressure on the intake.

A Cutoff Engine

Mr. Sargent stated the gist of his paper when he said "what we want to get is a cutoff engine."

Mr. Gruenewald stated his belief that any increases which could be obtained in this way in the thermal efficiency of an engine by changing the cutoff would not be sufficient in the minds of owners to make up for the increased complication.

Mr. Combs stated in a formal paper the point was made that 11,000 volts are necessary to overcome the pressure of 90 lb. per square inch. To this Heinze replied that not only the voltage is to be considered, it is also the current. It takes a pressure of 40,000 volts to puncture a glass plate ⅛-in. thick providing there is plenty of current behind it, but magneto current at 40,000 volts would not do it. He stated it was his belief that magnetos could be made which would spark in 200 or 300 lb. compression if needed.

Splitdorf-Apelco $10 Higher

NEWARK, N. J., April 3—An increase in price for the Splitdorf-Apelco electric starting and lighting system for Ford cars has been put into effect by the Splitdorf Electrical Co., the new price of $75 being an increase of $10. Higher cost of raw materials is solely responsible for the increase, according to the company.

Day-Elder to Build Trucks

$100,000 Concern Will Make 1-Ton and ½-Ton Models in Newark

NEWARK, N. J., April 1.—The Day-Elder Motors Co., this city, has been formed to manufacture motor trucks. The company is headed by Charles P. Day, for the last six years with the Universal Tobacco Machinery Co., Newark. G. A. Gemmer, the inventor of the Gemmer steering gear and who assisted in the organization of the Gemmer Mfg. Co., Detroit, is vice-president of the new company. F. G. Elder is treasurer. He has been an advertising man during most of his business career, having for the past nine years been treasurer of Sherman & Bryan, Inc., advertising agents in New York City. The new concern has been incorporated under the laws of New Jersey and is capitalized at $100,000.

The plant will be located at 161-167 Ogden Street, and will be occupied about April 15.

A 1-ton and a ½-ton model will be manufactured, the tonner selling around $1,400 and the other model at $850. These prices are at present only tentative, however, as no prices have as yet been definitely fixed.

The 1-ton truck will be equipped with a Continental four-cylinder motor developing 19½ hp. Other features are Bush radiator, Detroit Gear & Machine Co. transmission, and Sheldon front axle and springs.

The ½-tonner will use a Le Roi motor, developing 16 hp. Other features are a Grant-Lees transmission, Sheldon worm-drive rear axle, and Sheldon front axle and springs. This model will also be equipped with a starter.

Stroup Paige Purchasing Agent

DETROIT, MICH., March 29—P. E. Stroup has been appointed purchasing agent of the Paige-Detroit Motor Car Co. He held a similar position with Dodge Bros. during the last three years.

Sohlinger Flint Varnish Sales Manager

FLINT, MICH., March 30—W. J. Sohlinger, who during fourteen years was connected with the Sherwin-Williams Co., varnish maker in Cleveland, is now sales manager of the Flint Varnish & Color Works.

Von Rosen Is Saxon Sec.-Treas.

DETROIT, MICH., April 1—E. E. von Rosen, well known in the automobile industry, has been elected a director and also secretary-treasurer of the Saxon Motor Car Co., L. R. Scafe, formerly secretary-treasurer, having resigned. Mr. von Rosen was formerly comptroller of the United States Motor Co., and during the last three years was assistant comptroller, general auditor and assistant treasurer of the Maxwell Motor Co.

McCulla in Mexico Assisting Army

DETROIT, MICH., April 1—Wm. R. McCulla has left this city for Mexico to assist the government on mechanical and aerial transport. Mr. McCulla has had experience in the European war, having spent ten months in the war fronts on the other side.

Leonard Is Ferro Vice-President

CLEVELAND, OHIO, April 1—H. N. Leonard, who has been general sales manager of the Ferro Machine and Foundry Co., this city, was recently elected to the position of vice-president and general manager of the company.

Beane Is Mattson Representative

LODI, N. J., March 30—R. S. Beane, for many years associated with tire companies, has formed a connection with the Mattson Rubber Co., this city, Mr. Beane will be this company's special representative and will begin interviewing the larger dealers at once. The Mattson company reports a greatly increased activity, the plant now running three shifts.

Hopewell, of Chase & Co., Dies

BOSTON, MASS., March 31—John Hopewell, since 1870 a member of the firm of L. C. Chase & Co., manufacturers and commission merchants, this city, died this week in Washington, D. C. The Chase company manufactures, among other things, artificial leather for upholstery and other purposes. Mr. Hopewell was born in Greenfield, Mass., Feb. 2, 1845.

Corman Joins Elgin Co.

DETROIT, MICH., April 3—E. W. Corman, recently advertising manager of the Saxon Motor Car Corp., has joined the Elgin Motor Car Co., Chicago, in the capacity of director of sales and advertising.

Selden Is Scripps-Booth Asst. Mgr.

DETROIT, MICH., April 1—C. H. Booth, the president, has taken over the general managership of the Scripps-Booth Co., this city. C. G. Selden has been appointed assistant general manager. C. A. Erickson, who was formerly chief draftsman of the company, has been promoted to the office of chief engineer.

Chevrolet Plant for Ft. Worth

$600,000 Assembling Plant To Complete 15,000 Cars Per Year

FORT WORTH, TEX., April 1—The Chevrolet Motor Co. will build a $600,000 assembling plant in Fort Worth. The plant, which is to be chartered with a capitalization of $600,000, will cover approximately three acres of floorspace and will employ from 300 to 500 persons to begin with. The initial capacity will be 15,000 cars per year.

The building is to be constructed entirely of concrete and brick. The directors of the corporation will be Samuel Davidson, W. C. Stripling and N. H. Lassiter.

The Chevrolet company will also have assembling plants in Oakland, Cal.; Atlanta, Ga.; Minneapolis, Minn., and Kansas City, Kan. These are at present being established. The company now has plants in Flint, Mich.; Oshawa, Ont.; New York City, Tarrytown and St. Louis, Mo.

Packard's March Truck Business Amounts to $1,000,000

DETROIT, MICH., April 1—Orders calling for trucks to the value of $1,000,529.75 are on the books of the Packard Motor Car Co., showing the results of its domestic truck business for March. More than 99 per cent of the amount was for truck chassis; a majority of the buyers ordered bodies built by outside concerns. The company has delivered 4,308 Twin Six cars.

Hyatt Roller Bearing Co. to Equip New Process Steel Mill

LANCASTER, PA., April 1—An agreement has been filed in the courthouse at Lancaster, Pa., in which the Hyatt Roller Bearing Co. proposes to equip a mill there costing $50,000, for the New Process Steel Co., on the outskirts of the town. It is agreed that in return the Hyatt company will receive the products of the steel concern until the amount has been covered.

Sellon Chevrolet Supervisor

NEW YORK CITY, April 4—W. A. Sellon, for the past three years branch manager of the Brooklyn branch of the Chevrolet Motor Co., has been appointed retail store supervisor by that company. He will have charge of all the retail branches operated by the Chevrolet company and will be under the supervision of M. B. Leahy, factory sales manager.

Prest-O-Lite Completes Addition

New Building Will Increase Total Production to 1200 Batteries Per Day

INDIANAPOLIS, IND., April 1—An addition to the main factory of the Prest-O-Lite Co., 100 by 400 ft., which is the second largest building of the present factory group, is practically complete and will permit a total production of 1200 Prest-O-Lite storage batteries per day, three times the amount of the present output. The building is one story of reinforced concrete construction. Floors in one-half of the structure are of brick so as not to be affected by the action of acids. The roof is of reinforced concrete with a layer of cork under the roofing as an insulation against the sun's heat. Floor drains have been located at intervals of about 20 ft., and hose outlets provided at frequent intervals. Washing sinks will be placed at frequent intervals throughout the building and provided with mixing faucets so arranged that employees will wash in warm, running water.

Freight Hold-Up of Rubber Closes Knight Tire Plant

CANTON, OHIO, March 30—The Knight Tire & Rubber Co. has announced that it will be compelled to shut down, owing to the failure to obtain rubber from New York because of the freight congestion. About 125 cars are tied up in the East. About 500 men are affected.

Builds All-Steel Bodies

FREEPORT, ILL., April 1—The Stover Steel Tank Co., Freeport, has embarked upon a new side line, building all-steel bodies for commercial motor vehicles, no wood whatsoever being used in the construction. The Ford commercial all-steel body is made entirely from one piece of steel, with the exception of the hinged end-gate, and, under this form of construction, the makers entirely eliminate metallic sounds from riveted joints. In addition, the company is making all-steel express and stake bodies, ranging from the smallest to the five-ton trucks.

Streator Sale Brings $25,000

STREATOR, ILL., March 31—The real estate and buildings of the Streator Motor Car Co., now occupied by the Barley Mfg. Co., were sold at public auction by S. C. Eastman, referee in bankruptcy, for $25,000 to the Barley Mfg. Co. and the Streator Metal Stamping Co., the latter desiring to occupy a portion of the plant. The property consists of several modern buildings, has two switching tracks and 7 acres of land. The buildings and real estate have been used for several years by the Barley company, renting from the receiver. The stamping company has also been a tenant. The Barley company will continue to manufacture automobiles and supplies. The plant originally cost $75,000 and was installed by the defunct Streator Motor Car Co.

Overland Ships 47,465 Cars in Three Months

TOLEDO, OHIO, April 1—In the three months ended March 31, the Willys-Overland Co. manufactured and shipped a total of 47,465 cars, a new high record. This total comes within 1000 cars of equaling the entire yearly output of 1914. Output in March was 19,780, compared with 7005 in March, 1915, a gain of 12,775.

Jordan Plant for Cleveland

CLEVELAND, OHIO, March 31—A plant will be erected in this city for the Jordan Motor Car Co. A 5-acre site has been purchased on East 152nd Street, south of St. Clair Avenue. Ground will be broken at once. Cost will be $50,000.

Baltimore Tire Acquires Plant

BALTIMORE, MD., April 3—The Baltimore Rubber Tire Mfg. Co., this city, acquired a plant April 1 and will be ready to turn out its product on July 1. The plant will be located at Orangeville, the former home of the Maryland Mantel & Tile Co., and the group of buildings acquired is ideal for the manufacture of tires and inner tubes.

The capital stock of the new company is $200,000, all common. The company eventually expects to employ between 500 and 600 men, and the officers are G. W. Habbersatt, president; H. M. Rover, secretary-treasurer, and A. S. Mauk, vice-president and general manager. Mr. Mauk holds patents on several well-known tires. He has been identified with some of the leading rubber tire plants in the country.

Chevrolet Takes Cycle Co. Capacity

NEW YOPK CITY, April 1.—The Chevrolet Motor Co. has entered into an arrangement with the National Cycle & Mfg. Co., Bay City, Mich., to control its capacity for an indefinite period. The National Cycle & Mfg. Co. owns two plants, covering 5½ acres, is equipped to build motors and parts and employs from 1500 to 2000 men.

Wolverine Car and Tractor Organized

DETROIT, MICH., March 30—The Wolverine Car & Tractor Co. has been incorporated here with a capital stock of $300,000 by William J. and T. J. McNamara and William J. Wagenhals.

Night Work Lowers Efficiency

Study of Work and Output Shows Day Workers' Record Is 40% Better

SYRACUSE, N. Y., March 30—That workmen in factories on night shifts are 40 per cent less efficient than those working on day shifts is the conclusion of George D. Babcock, production manager of the H. H. Franklin Mfg. Co., this city. Mr. Babcock, after studying the efficiency of night factory forces, concludes that even with greatly increased supervision per man and with special incentives for night work, such as 10 cents extra per hour to the night men, it is impossible to get from the night forces more than 75 per cent of the efficiency obtained from the day shift. Mr. Babcock has further discovered that while the output efficiency of night work is much lower, the regularity of workmen is reduced and the amount of rejected work is much greater at night than in the day. This situation is not entirely due to artificial lighting or to less satisfactory shop conditions, but principally to the lack of willingness of first-class workmen to work nights, and to an increased fatigue on account of carelessness in the hours of rest and sleep. The daily hours of sleep are not so regular with a person on night work as with one on day work. Mr. Babcock believes that sleeping during the day develops nervousness which tends toward restlessness.

Tests at Other Plants

That the efficiency of a workman is not so great at night has been demonstrated at other factories. In one Cleveland factory the test made some years ago showed that the output of a day force dropped off materially when the electric lights were switched on at four o'clock on the winter afternoons. The electric current for the machinery and also for the lights was drawn from the same switch board and it was found that the consumption of current after the lights were turned on was actually a little less than before. This can only be explained by the fact that the men were not working at the same capacity and the different machines were considerably below their average output.

Chalmers to Assemble in Oakland

OAKLAND, CAL., April 3—The Chalmers Motor Co., Detroit, will erect an assembling plant in this city. It will employ from 300 to 400 men at the start and turn out twenty-five to thirty cars a day. The announcement was made before the Chamber of Commerce at a luncheon given for Hugh Chalmers.

No Packards for 1916 Races

Will Appear on Speedways But Not in Competition—Test Aeroplane Motors

DETROIT, MICH., April 3.—There have been a great many rumors concerning the probability of the appearance on the speedways this year of Packard racing cars. It is now finally settled that while such cars will undoubtedly appear no Packards will be entered for any competitive racing during 1916. For several months past the Packard engineers have been engaged upon the design of aeroplane engines, and J. G. Vincent proposed to follow the example of the Mercedes company, which tried out its aeroplane motor by fitting it in a racing chassis.

Recent European experience goes to show that no engine is better suited to aeroplane requirements than the twelve-cylinder and the Packard experiments will therefore be along the line of finding out the power and weight limitations of this type of engine. Experiments probably will be made with several different sizes ranging from about 300 cu. in. upward.

Preliminary tests on the block have been very encouraging, and there seems no doubt that the smallest experimental twelve will be capable of driving a chassis at a very high speed.

Want Rickenbacher on Coast

CHICAGO, ILL., March 27—Eddie Rickenbacher, manager of the Prest-O-Lite racing team, may be a contender in the Corona grand prize, April 8, and in the Ascot meet, April 16. Rickenbacher states he has been offered the Bentel Mercer for both events, and has been informed by George Bentel that the car is in perfect shape. He will accept the offer if his work at Indianapolis will permit it.

300-Cu.-In. Milac Building

LOS ANGELES, CAL., March 31—The Linthwaite-Hussy Motor Co., of this city, builder of the Milac car of 199 cu. in. piston displacement which Teddy Tetzlaff drove in the Ascot speedway event March 5, is building another Milac on the same lines which will just come under the 300-cu. in. regulations. This second car is to be driven in the Corona Grand Prix April 8, and then be shipped East to compete in the Indianapolis classic.

Anderson May Be Independent

INDIANAPOLIS, IND., March 27—Gil Anderson, champion speedway driver, probably will be the manager of the new Stutz team of racing cars for the 1916 season. It is reported that Anderson is negotiating with Harry Stutz for the use of the three white cars which he managed last year. Whether or not the withdrawal of Stutz from racing last year will prevent the use of the cars under independent management has not been determined.

Of the four Stutz cars in the team last year, one is now being raced in California by Earl Cooper. Anderson hopes to take the other three, in which case Tom Rooney will be a second driver. The third has not as yet been decided upon.

Sixteen Entries to Date for Corona Grand Prize

CORONA, CAL., April 2—Sixteen entries have been made so far for the Corona boulevard race on April 8. The first official practice on the course is to be held to-morrow afternoon. Two informal practices have been held in which some of the drivers entered in the Corona Grand Prize turned some fast laps.

During an informal practice spin, yesterday, Hughie Hughes on his first trial on the Sunbeam 12, turned a lap at 106 m.p.h. Earl Cooper on the Stutz made a lap at the rate of 97.7 m.p.h. O'Donnell on the Duesenberg showed 95 m.p.h. in his first try-out with the drivers.

Car	Driver	Car	Driver
Delage.	Oldfield	Sunbeam	Hughes
Peugeot.	Burman	Edwards.	Edwards
Milac.	Tetzlaff	Cyclone.	Durant
Onar.	Toft	Mercer.	Thomas
Apperson	Price	Gandy Sp.	Waterman
Mercer.	Pullen	Gandy	Lou Gandy
Stutz.	Cooper	Marmon.	Welsh
Duesenb'rg.	O'Donnell	Tahis	Teel

Seven Chicago Amateur Entries

CHICAGO, ILL., April 3—With the Chicago amateur driver's race over six weeks away there are twenty-five entries promised and seven actual entries for the event. Those who have actually signed the entry blanks and deposited the fee are as follows:

Driver	Car	Club
F. C. Sawyer	Mercer.	South Shore Country Club.
William Leet	Mercer.	Omaha Automobile Club.
Dr. R. R. Duff	Mercer.	Central District Mfg. Club.
H. W. Mershback	Packard.	Chicago Automobile Club.
C. H. Robbins	Mercer.	Speedway Park Association.
William Robbins	Mercer.	South Shore Country Club.
E. C. Church	Cadillao.	Chicago Automobile Club.
Frank Warner	Cadillac.	Chicago Automobile Club.
Bronsted.	Mercer.	Chicago Automobile Club.

Bourne Magnetic Truck Co. Formed

DOVER, DEL., March 30—The Bourne Magnetic Truck Co. has been formed in this State with a capital of $2,000,000 to manufacture and deal in motors, engines, wagons, etc. The incorporators are H. E. Latter, N. P. Coffin, C. M. Egner.

Christiaens to Race at Indianapolis

Will Drive Sunbeam—René Thomas Cannot Appear—Fiat Not to Enter

PARIS, April 3—*Special Cable*—Joseph Christiaens, the Belgian who drove the six-cylinder Excelsior into sixth place at Indianapolis two years ago, is an assured entrant with a six-cylinder Sunbeam in the 300-mile Indianapolis Speedway race, May 30. The report, however, that René Thomas, winner of the 500-mile race on the Indianapolis Speedway in 1914, will drive a Peugeot in that race, is incorrect. Though the Fiat company has been redesigning two 1914 Grand Prix models and it was almost certain the company would enter these in the coming Indianapolis race, it is now stated that this company has decided to the contrary.

To Convert Chicago Speedway Stock—Ben Hur Racers

CHICAGO, ILL., April 3—David F. Reid, president of the Speedway Park Association, has secured an option on all the common stock of the association, a move which will eventually release it from the hands of contractors who now hold all the outstanding shares. He states that the shares under option will be converted to membership certificates.

Attorneys for the association have recently incorporated a company with a capital of $100,000, headed by Mr. Reid, which will sponsor the Ben Hur special racing team to represent Chicago at all the big races. It is expected the new cars will be ready for the May races in New York and Indianapolis.

Patterson Heads C. A. C. Amateurs

CHICAGO, ILL., March 27—E. C. Patterson, former backer of Ralph De Palma, has been elected captain of the Chicago Automobile Club team for the invitation non-professional drivers' race at the Chicago Speedway, May 20. It is expected that there will be a large entry list from the local motoring organizations as well as from other clubs in the vicinity. The Rotary Club has named five entrants, and a number of the Chicago sportsmen were out for unofficial practice Saturday. Arrangements were made for official practice Sunday, but weather conditions did not permit it.

Master Drivers Run Annual Event

CHICAGO, ILL., April 4—The three-day reliability run for the master driver's medal, which was won last year by E. A. Turner, driving a Mercer, will be repeated this season, probably in October, and will be made an annual event.

New Financing Co. Formed

Guaranty Securities Corp. Plans to Finance Time Sales of 21 Makes

NEW YORK CITY, April 1—A new plan for financing time sales of automobiles which is not restricted to any one particular make, has been announced by the Guaranty Securities Corp., New York City, which is an outgrowth of the Guaranty Securities Co., Toledo, that was originally formed to finance time sales of Overland automobiles.

The plan as worked out by the new Guaranty Securities Corp. is very simple and consists simply in selling a man a car on a cash payment of from one-third to one-half the list price of the car and the balance in eight equal monthly payments or fewer installments if desired. To this is added in cash 2½ per cent of the list price to pay for necessary insurance and incidental expenses if the car lists at $600 or more, or 3 per cent if the selling price is under $600. The insurance is for full 80 per cent fire and theft coverage for one year.

At the present time the Guaranty plan has been extended so that the following cars may be sold by the dealer under its provisions: Ford, Hudson, Studebaker, Paige, Chevrolet, Reo, Oakland, Overland, Buick, Chandler, Maxwell, Kissel, Oldsmobile, Willys-Knight, Cadillac, Chalmers, Dodge, Jeffery, Hupmobile, Mitchell and Franklin. The credit concern intends to inaugurate a large national campaign to inform the general public of the plan, which will probably be widened in its scope as time goes on.

The customer gets the immediate use of his car and pays 6 per cent on the deferred payments. The schedule of payments for cars of different prices is given below:

SCHEDULE OF PAYMENTS

Price of Car	Cash Payment Required, % of List	Amt. Payable on Def. Payments, % of List
$ 750 or less	33⅓	66⅔
751 to $1,250	40	60
1,251 to 1,500	45	55
1,501 or more	50	50

The dealer pays no interest or premium, but when the customer has signed a contract in accordance with instructions given by the Guaranty concern, the dealer indorses it and sends it on to the credit house. The dealer keeps all the cash including the amount collected for insurance and incidental expenses. In addition to this the Guaranty Securities Corp. sends to the dealer immediately the amount of the deferred payments due from the customer, except the insurance and incidental collections and 20 per cent of the deferred payments. For this amount a deferred certificate is issued to the dealer, in which the Guaranty Securities concern agrees to pay the remaining 20 per cent as soon as the customer finishes paying for the car.

To show how this works out, the following is given:

Dealer sells a car listing at...	$1,000	
Dealer adds for insurance and incidental charges.......... (2½% of list over $600).	25	
Customer pays down on car (40%)		$400
Customer pays down for insurance, etc.		25
Customer gives contract note for deferred payments, $75 per month for 8 months.....		600
	$1,025	$1,025
Guaranty Securities Corp. buys contract note at face value..		$600
Guaranty Securities Corp. holds cash on deferred certificate till payments on contract note are completed (20%)...		120
		$480
Guaranty Securities Corp. deducts cash received for insurance, etc., and retained by dealer		$25
Guaranty Securities Corp. pays dealer cash immediately....		$455
Customer pays dealer cash on delivery (as above).........		$425
Dealer receives immediately in cash		$880
Guaranty Securities Corp. redeems deferred certificate in cash when payments on contract note are completed....		$120
Dealer receives full list price..		$1,000

Tentative Program for Salesmanship Congress

DETROIT, MICH., April 4—Though the program that will be taken up at the World's Salesmanship Congress here, July 9 to 13, has not been finally decided, a tentative program has been prepared. Who all the speakers will be has not yet been fully decided. A large number of well-known men in the different industries of the country are eligible.

Some of the subjects suggested to be taken up are: Are Salesmen Born? Can Psychology Make Salesmen? What Does It Cost To Make a Salesman? Ethics of Salesmanship; Comprehensiveness of Salesmanship; Selection of Salesmen; Education of Salesmen; Direction of Salesmen; Salesmanship in Public Schools; Salesmanship in Universities; Salesmanship's Health; Real Estate Salesmanship; Insurance Salesmanship; Sureties Salesmanship; the Price-Cutting Manufacturer; the Discounting Jobber; the Bargain Sale Retailer; Sales Letters; Magazine and Newspaper Advertising; Premiums and Souvenirs; Selling to South America; Selling to Germany; Selling to Great Britain; Debate on the Question, Is Advertising Salesmanship?

New Charging Station Booklet Out

NEW YORK CITY, April 4—The New York Electric Vehicle Assn. has issued a new booklet with maps showing the charging stations, routes and giving data over the entire metropolitan area, including all of New Jersey.

Dealer Loses Broken Wheel Suit

Canadian Court Holds Him Responsible as Maker's Representative

MONTREAL, QUEBEC, March 31—According to a judgment rendered in the Court of Review yesterday by Justices Fortin, Guerin and Archer, the vendor of an automobile, when he is acting as agent for the manufacturers, is bound to assure himself that the machine is well constructed and in perfect order, according to the guarantee, as he may be held responsible under the law for any damages which result from defects in the automobile.

It was proved that a defective wheel in the automobile which formed the basis of the action caused the death of the purchaser, J. Philippe Pothier. His widow sued P. A. D. Robert, from whom her husband bought the automobile, for damages, and Justice Hutchison, in the Superior Court at Sherbrooke, awarded her $2,500 on this stated ground:

Rotten Wood Used

"That the proof establishes beyond doubt that the accident was due to the rotten condition of some of the spokes of the left hind wheel of the said car, which collapsed or smashed and broke away from the hub of the wheel, and which caused the car to overturn." Robert appealed from this judgment, but yesterday it was unanimously confirmed by the Court of Review. "This may not be very popular with makers and sellers of automobiles," remarked Justice Fortin, "but it is according to the law."

Justice Guerin said: "Were I a judge sitting with the powers of a police magistrate, and application were made to me for a warrant for the arrest of the manufacturer who put such rotten wood in the wheel of this automobile, charging him with manslaughter, I would sign the warrant. In selling such an automobile he was selling a machine in a condition that endangered life. So far as the manufacturer is concerned it was criminal. So far as the vendor is concerned, it was not a crime, but it was a fault for which he is liable for damages."

Justice Archer held that the negligence on the part of the manufacturer was "gross if not criminal," and while the responsibility of the vendor of the machine was not the same, he said the man was nevertheless remiss and liable for damages.

Maker Is to Blame

"There can be no doubt that if the automobile had been sold directly by the manufacturing company to Pothier the company could have been held responsible in damages. I am also of the opinion that, as a general principle, an automobile merchant ought to be put on the same footing as the builder or manufacturer of the automobile. The vendor in the present action is something more than a salesman in the ordinarily accepted sense of that term. He said in his evidence that he was the agent of the company, and as such gave demonstrations in order to show to clients the superiority of the automobile he had for sale. He further told the court that he conducted tests before delivering the automobile in order to be assured that the machine was in good order, and the tests that he generally made were sufficient to establish if the wheels were in good condition. This enabled him to ascertain for himself the quality of the material used in construction and assure him in giving guarantees, as he did in the present case, that the automobile was in perfect order. Notwithstanding the fact that he gave such guarantee in this instance, he does not appear to have made such tests."

Gemmer Increases Capital $200,000

Detroit, Mich., March 30—The Gemmer Mfg. Co., manufacturer of steering gears, has increased its capital stock from $300,000 to $500,000. This concern's business has been increasing in such a way during the last few months that, notwithstanding enlargements of the plant which were made last year, the additions did not permit the increasing business to be taken care of as well as desired. For this reason further extensions will be made and the working force increased.

Lozier Capital Now $700,000

Cleveland, Ohio, April 1—The H. A. Lozier Co. has increased its capital from $10,000 $700,000.

Accessory Forgings Capital $50,000

Detroit, Mich., March 30—The Accessory Forgings Co. has increased its capital stock from $10,000 to $50,000.

Cleveland Machine Co. Reorganized

Ohio Corporation With $4,000,000 Capital Succeeds New Jersey Concern

Cleveland, Ohio, April 1—The Cleveland Automatic Machine Co., an Ohio corporation, has succeeded the company of the same name, which was a New Jersey corporation. The capital stock of the new company, which was originally placed at $1,000,000, has been increased to $4,000,000. The company has sold to William Solomon & Co. of New York and Secor & Bell of Toledo, Ohio, the $1,500,000 7 per cent preferred stock, par $100, and this will be offered to the public. The $2,500,000 common stock, it is stated, will not be publicly offered. The preferred stock is to be redeemed through a sinking fund which will be formed by the retention of 10 per cent of the net earnings, but this annual amount is to be not less than $50,000. The stock is callable at 115. The stock of the old company, all of one class, had always been closely held, but this marks the entrance of banking interests into the business.

The operation of the business remains in the hands of the old organization, whose officers are: President, A. L. Garford, Elyria, Ohio; vice-president and general manager, James Brophy; treasurer, H. M. Rich; secretary, George Cook Ford.

Rubber Goods Net Earnings Amount to $2,037,744

New York City, April 1—The Rubber Goods Mfg. Co. for the year ended Dec. 31, 1915, showed net earnings of $2,037,744 as against $2,084,626 in 1914. Net profits amounted to $1,330,166 as against $2,193,220 in 1914.

The reports says: "While the sales of the company both in quantity and value were larger in 1915 than in 1914, the net earnings were less on account of special conditions in the tire department. These adverse conditions made themselves felt throughout the entire heavy buying season, but from September on and continuing until Jan. 1 of this year up to date a marked improvement has occurred in the tire department."

Market Prices Steady

New York City, April 5—Market prices last week were somewhat steady. Aluminum and lead with 5-cent rises and a decline in crude rubber were the features of the market activities. Aluminum rose to 70 cents a pound, a new high mark, while lead reached $8.00 per 100 lb. Para rubber declined 1 cent a pound to 74, while the Ceylon latex grade dropped 3 cents to 88 cents. Liberal arrivals of crude rubber were reported from Brazil yesterday. Despite the numerous reports of an active trade in rubber goods manufacturers show little disposition to purchase.

Steel prices remained constant last week. Both Bessemer and open-hearth steels are quoting at $45 per ton. Copper is firm at 28½ cents a pound. Beams and channels rose to $2.68 per 100 lb. at a gain of 6 cents.

Dividends Declared

Chicago Pneumatic Tool Co.; quarterly of 1 per cent on all stock at close of business April 15, payable April 25.

General Motors Co., regular quarterly of 5 per cent on common and 3½ per cent on preferred, payable May 1, to stock of record April 18.

Kelly-Springfield Tire Co.; quarterly of 4 per cent or $1 a share on common, payable May 1 to stock of record April 15.

Vacuum Oil Declares 3 per Cent Extra Dividend

New York City, April 1—The Vacuum Oil Co. has declared an extra dividend of 2 per cent as well as the usual semi-annual payment of 3 per cent, payable May 15, to stockholders of record May 1. The annual statement showed that net earnings in 1915 had been equal to more than 40 per cent on the $15,000,000 outstanding shares. The income account shows net profits of $6,861,913 against $2,075,644 in 1914.

6 Per Cent Dividend for Bowser Employees

South Bend, Ind., April 3—It has been announced by the management of the S. F. Bowser Oil Tank & Pump Co., Fort Wayne, Ind., that all employees of the plant will receive a dividend of 6 per cent on their wages for the month of February. It was stated by President Bowser that the company is planning to issue to each employe an insurance policy of $1,000 and an age pension.

Chevrolet Features Securities

Reaches 183 Compared with 85 in Oct.—Firestone Common Goes Up 20 Points

NEW YORK CITY, April 5—Chevrolet stock went up to 183 yesterday, compared with 85, at which the bankers offered the stock last October, representing an advance of over 100 per cent. This is the most rapid appreciation shown by any of the securities offered in recent years.

Maxwell and Goodrich Strong

Maxwell and Goodrich were very strong last week. Maxwell common, first and second preferred closed on Saturday with gains of 2¼, and 1¾ points, respectively. Maxwell and Studebaker have been the target of pool activities at various times during the past year, and it was rumored that a well-known speculator who has been absent from the floor of the exchange for some time and who returned on Monday was beginning a new campaign in these issues.

Goodrich, it is stated, will earn not less than 25 per cent on its common during 1916. It is understood that the February net of that company was 85 per cent ahead of the same months of last year.

Gasoline Not a Factor

So far the widely heralded crisis existing in the gasoline situation has not hurt the securities prices. Automobile stocks are being purchased on the theory that the Mexican affair is going to lead the American army far into the wilderness, where numerous automobiles and especially trucks will be needed. It is also believed that should real intervention follow and Mexico be occupied by a large American army, thousands of American business men will follow the army into the choice business sections of the country. They will need automobiles of all types because the railroads are not adequately developed.

$3,000,000 Orders from Russia—Not War Sales

NEW YORK CITY, March 31—That the market for American-made automobiles in foreign countries was never better is shown in reports of orders now on hand by the large exporting houses in this city. One house, Gaston, Williams & Wigmore, alone has on its books orders for $3,000,000 worth of touring cars and trucks from dealers and merchants in Russia. None of this business is with the Russian Government, but represents the foreign demand for American automobiles by automobile users in Russia.

Bock Bearing to Be Reorganized

TOLEDO, OHIO, April 1—Incorporation of the Bock Taper Roller Bearing Co. this week is the beginning of the reorganization of the Bock Bearing Co., West Toledo. The initial capital stock is $10,000, but this is preliminary to increasing the capital stock of the present company. C. E. B. Lamson, J. E. Dunipace and C. H. Clements are the principal incorporators.

King Holds Annual Speedfest

Host to Parts Manufacturers and Their Representatives—Business Talk Barred

DETROIT, MICH., April 1—A large number of parts makers and their representatives were the guests to-night of the King Motor Car Co., at the third annual King Speedfest, at Hotel Statler.

The purpose of this annual gathering is to get better acquainted. The unusual conditions prevailing in the automobile industry owing to the great war, the shortage of materials, the freight car situation, and the many other things which make the situation entirely abnormal this year, brought about many an interchange of views among the many men representative of the industry in general, although business talks were barred.

Some Materials Less Scarce

From what the parts makers had to say it appears that, while the general condition of the materials situation is still as bad as it has been for many months, the scarcity of certain raw products is not quite so pronounced. The parts makers are in the same situation as the car makers, inasmuch as they are able to get certain supplies of raw materials without too much trouble, while other needed supplies are very difficult to secure, even at the greatly increased prices which are quoted at present.

Balk Gasoline Probe Resolution

Senate Holds Up Vote Till Trade Commission Report Is Made

WASHINGTON, D. C., April 1—After a hot debate the Senate this week failed to put the Martine resolution, directing an investigation of the high price of gasoline by the Attorney General, through its final parliamentary stage, and therefore the resolution is expected to come up again. The Senate adopted the resolution, but the preamble, asserting that the Standard Oil Co. was a trust and was responsible as such for the price of gasoline, was not voted upon finally. Until the preamble is acted on or amended and adopted the resolution is not complete, especially as the body of the resolution does not mention "gasoline" at all but merely refers to it as an article.

Senator Martine has announced that he will call up his resolution again at the earliest opportunity, but the impression prevails that he will not be able to get any action before the report of the Federal Trade Commission on the gasoline and oil subject is sent to Congress. The report is rapidly nearing completion, and probably will be sent to Congress on or about April 5.

40 Cents in Two Months?

The gasoline subject was also up in the House this week, when Congressman Howard of Georgia, in introducing a resolution authorizing the President to declare an embargo on the exportation of gasoline, startled the House with the prediction that gasoline for the use of the Government itself in huge quantities will reach a wholesale price of 40 cents in the next two months. The Howard resolution was written after the author had a talk with Secretary of Commerce Redfield, who presented some startling facts. At the same time Congressman Steenerson of Minnesota introduced a bill to give the Federal Trade Commission the power to fix prices on gasoline and allied products. It is doubtful if any action will be taken on the Steenerson bill.

"I was told by Secretary Redfield," said Congressman Howard, "that the contract price for gasoline for Government consumption last year was 11 cents. Now the producers are coming here for contracts and will not listen to any suggestion less than 40 cents."

"Government investigators report that the high price of gasoline prevailing is due to artificial rather than economic means," said Congressman Steenerson, "and yet the Department of Justice says it can find no sufficient evidence to warrant prosecution under the anti-trust laws. Here, therefore, is an instance where the competitive system has failed to secure to the people reasonable prices of one of the prime necessities of life, and we must either submit to exploitation by monopoly prices or have prices fixed by authority of Congress. That Congress has the power cannot be questioned.

"In the Federal Trade Commission we have already an instrument suited to the work. Its members have already investigated the subject, and say they can determine to a fraction of a cent per gallon just what it costs to produce and deliver this commodity in any part of the country where it is now dealt in."

Rittman Resigns—To Head New Gasoline Concern

PITTSBURGH, PA., April 1.—Dr. Walter F. Rittman, chemical engineer of the Bureau of Mines and inventor of the new process for obtaining a much greater yield of gasoline from crude oil, has resigned his position with the Bureau to become head of a company being organized for the purpose of manufacturing gasoline. It is stated that the local automobile dealers' association has been negotiating with Dr. Rittman in regard to a plan to reduce present gasoline prices. It is thought that Dr. Rittman and his company will figure in the plan.

$4,000,000 Fuel Co. Formed

DOVER, DEL., April 5—The People's Engine Products Co., with a capital of $4,000,000, was formed here yesterday to manufacture, produce and refine, buy, sell and handle petroleum, gasoline, gas and lubricating oils. The incorporators are H. E. Footh of Pittsburgh, H. C. Swann of Bellevue, Pa., and R. Robbins of Crafton, Pa.

Thielens a Studebaker Director

NEW YORK CITY, April 5—Sales of the Studebaker Corp. for the quarter ended March showed an increase of 100 per cent over those for the corresponding period of a year ago. The production is being maintained.

At the annual meeting of the stockholders the retiring directors were reelected. At the directors' meeting for organization, following the annual meeting of the stockholders, A. B. Thielens was elected a director, succeeding D. M. F. Weeks, resigned.

Hale Joins Haynes Stellite

ELKHART, IND., April 1—P. P. Hale has resigned his position as chief draftsman of the Sun Motor Car Co., this city, to accept a position in the sales organization of the Haynes Stellite Co., Kokomo, Ind.

Boycott Standard Oil Co.

Pittsburgh and Minneapolis Dealers Make New Move for Cheaper Gasoline

NEW YORK CITY, April 1—Agitation from different sections of the country for a Federal investigation of the inflated prices of gasoline is becoming more acute as each day passes.

The Pittsburgh Automobile Dealers' Assn. has agreed to buy no more gasoline from the Standard Oil Co. until its prices are justified. The association is overlooking nothing in its campaign for a substantial reduction in gasoline prices. Every buyer of a car in that city will be asked to refrain from buying from the Standard Oil Co. until prices come down to normal basis.

Federal investigation has been asked of Congress by the Minneapolis city council. The council asks for a consideration of the alleged control by the Standard Oil Co. of crude oil production and for an embargo on shipments of oil to warring nations. The situation in fact has become so acute in that city, that the Standard Oil Co. has practically been asked not to open any more filling stations in that city until it has cleared itself of all insinuations and charges as to monopoly and price manipulation.

A similar investigation has been asked by the Ohio State Automobile Assn. in Akron. This faction too believes that an embargo on exportation would relieve the situation.

In Detroit, a sort of provisional organization to discuss ways and means of combating the present gasoline situation has been formed by six representatives of automobile factories in that city, six dealers selling cars, and six garagemen. A resolution was passed asking the National Automobile Chamber of Commerce to push whatever measures are deemed necessary to relieve the situation by congressional action, embargo or other means.

Cleveland S. A. E. Meetings

CLEVELAND, OHIO, April 3—Secretary C. S. Pelton of the Cleveland Section of the S. A. E. has called the attention of members of the engineers' organization to the dates of meetings arranged by the Cleveland Section. Meetings will be held April 21, May 19, and a field day some time during June.

Motor Fuels Co. Formed

ST. JOSEPH, MO., March 31—Motor Fuels Co., capital stock $100,000; to exploit refining patents held by S. M. Herber; incorporators, S. M. Herber, J. C. Sanders, J. L. McQueen, William Taylor and Mabel Morgan.

Tire Cos. Winners In Monopoly Suit

Automobile Co-Operative Assn. of America Loses—Asks for New Trial

CLEVELAND, OHIO, April 1—The jury in the Federal District Court returned a verdict for the defendants yesterday in the case of the Automobile Co-Operative Association of America against the B. F. Goodrich Co. of Akron, B. F. Goodrich Co. of New York, the Diamond Rubber Co. of Akron and the Republic Rubber Co. of Youngstown, Ohio. The original petition included the Firestone Tire & Rubber Co. and the United States Rubber Co., but they were dismissed before the trial began.

In each case the petition was directed against the officers of the companies personally, as well as the companies themselves.

Defendants were charged in the petition with having formed and operated a combination in restraint of interstate and foreign trade and plaintiff claims that through this alleged combination its own business was destroyed and it lost the $75,000 capital with which it began business.

These companies, it was alleged, sold tires and other rubber goods and allowed a discount, usually from the retail price, which went as a profit to the dealer, but shortly after the plaintiff began business, it was charged, this combination was formed and prices were fixed arbitrarily, thus excluding the plaintiff and others from buying and selling freely and obtaining automobile accessories.

The petition charged that dealers were sent communications which frightened them and prevented them from buying goods of other companies and that defendants refused to sell to any one who furnished goods to plaintiff at wholesale prices. It was also alleged that blacklists, containing plaintiff's name, were distributed and that an agreement existed between defendants and an association of retail dealers in New York City by which the dealers were prevented from selling anything to plaintiff.

In addition to the alleged loss of its capital, plaintiff alleged that its profits, estimated at $50,000 annually, had also been lost. It asked judgment threefold the damages adjudged, and other sums that would have brought the entire amount up to $450,000.

The Automobile Co-operative Association has filed a motion for a new trial.

Receivers for Mason-Seaman Taxicab

NEW YORK CITY, April 1—The Mason-Seaman Transportation Co., one of the largest taxicab companies in this city, was placed in the hands of receivers yesterday. Lower taxicab rates and the present high cost of gasoline figured prominently in the reasons given for the failure of the company.

The company is capitalized at $10,000,000 and was organized in 1914 to take over the Mason-Seaman Transportation Co. and the Yellow Taxicab Co.

The company has 1000 touring cars and taxicabs on hand. The value of the assets is not given, but the liabilities are set down as $400,000.

Metric System Bill Provides $500 Fine or Jail

WASHINGTON, D. C., April 1—A bill for the compulsory use of the metric system has been introduced in Congress. According to the bill, after July 1, 1924, all Americans may have the choice of breaking the law or of using the metric system; any person, corporation, company, society, or association who shall use, or offer and attempt to use, in any industrial or commercial transaction in the sale or purchase of any commodity any other weights and measures than those of the metric system shall be guilty of a misdemeanor, and upon conviction thereof in any court shall be punished by a fine of not more than $500 or by imprisonment for not more than three months, or by both such fine and imprisonment. Frederick A. Halsey, who led the fight against the metric system a decade ago, is again leading the opposition to the measure, which is known as the Dillon bill.

58,502 Cars Bought in Ohio in 1915

COLUMBUS, OHIO, April 1—Statistics prepared by Fred H. Caley, secretary of the Cleveland Automobile Club, and submitted at the annual meeting of the Ohio Automobile Association showed that the State of Ohio purchased 58,502 cars during 1915, which was the largest number sold in any State in the union. According to the statistics New York was second with 56,671 cars; Illinois third, with 51,150 cars; Pennsylvania fourth, with 43,588 cars, and California next, with 40,700 cars. Basing the figures on the 1916 U. S. census estimate, there is now one car to each twenty-eight people in the Buckeye State.

According to a report made by W. H. Walker, Ohio registrar of automobiles, covering the present year up to and including March 28, the department has issued 121,000 sets of licenses to gasoline automobile owners in the State since the first of the year. It was late in May last year when that number was reached. Up to date the department has issued 2361 licenses to dealers and 7981 licenses to owners of electric cars.

Bay State Regulates Lighting

All Vehicles Must Light Lamps at Same Time—Other Measures

BOSTON, MASS., April 3—Governor McCall has signed two of the bills of interest to automobilists that have reached him. One of these provides that all vehicles shall display their lights half an hour after sunset and half an hour before sunrise. The law compelled the motorists to light up at those times, but the owners of other vehicles did not have to light their vehicles until one hour after sunset, so the new law makes the time uniform for all vehicles.

Another measure signed allows an automobilist in an adjoining State who lives within 15 miles of the border to register his car in the Bay State for a fee of $2. This is the law in New Hampshire and Maine, and allows business men to run back and forth without having to pay a yearly registration in both States.

The bill to allow the sale of gasoline and to make repairs on Sunday went through all the branches. Then it was killed in the Senate, but reconsideration was granted, and it is still in abeyance. A bill to compel all motorists to take out a $2,000 bond before driving their cars was killed, and the bills to compel all owners to pass a physical and mental test, and the other to take the discretionary powers from the Highways Commission were also killed, but not until they had reached close to the enactment stage.

Wisconsin Registrations Gain 70 per Cent

MILWAUKEE, WIS., April 1—A total registration of 51,000 cars by private owners at the close of business March 31 is the unprecedented record of the State of Wisconsin. A year ago the total registry for the first quarter of 1915 was slightly under 30,000, showing a gain of 21,000, or 70 per cent. Although the Department of State planned only on a registration of 100,000 for 1916, predictions are freely made that the number will run up to 115,000 before the end of the year.

Must Stop, Look and Listen at R. R. Crossing

LANSING, MICH., March 30—That an automobile driver when about to cross a railroad must stop, look and listen in such a way and at such a distance from the crossing that it really can be shown that he took all necessary precautions, is a decision of the Supreme Court of Michigan, in the case of J. S. Sanford of

Battle Creek against the Grand Trunk Railroad.

In his opinion, Judge Brooke states, "The duty of an automobile driver approaching tracks where there is restricted vision, to stop, look and listen, and to do so at a time and place where stopping, and where looking and listening will be effective, is a positive duty and the safeguarding steps the plaintiff failed to take. He stopped where stopping served no purpose, and failed to stop where stopping would have disclosed danger. He made chance and not sight, the guarantee of his safety."

Collins Curtain Maker Wins in Patent Suit Appeal

DETROIT, MICH., March 31—The award of $20,000 damages to W. A. Paul as a result of his suit against J. N. Collins, J. A. Bennett and the Novelty Leather Works, maker of Collins Curtains, claiming invention on a curtain holder for inside curtains on automobiles, has been set aside by the Supreme Court of Michigan, which has reversed the decision of the Wayne County circuit court on Jan. 22, 1915.

The patent involved was No. 1,066,448, filed by Collins July 22, 1912, and granted to him July 1, 1913. The attorneys for Collins, Bennett and the Novelty Leather Works appealed the case, claiming that the circuit court had no jurisdiction in the matter and that the case should have been heard in the Federal courts.

Troy Trailers for U. S. Army

TROY, N. Y., April 1—The United States Government bought eleven 2½-ton Troy trailers for use in the punitive expedition against Villa in Mexico on March 21. These trailers were shipped by a special train which made passenger train time on the trip to El Paso, Tex.

There was not time enough to give the finishing touches in the factory and a squad of painters was sent along to give the trailers the second coat and striping on the run.

Garagemen Liable for Employees

COLUMBUS, OHIO, March 31—In a decision handed down by Judge Ruth in the Municipal Court owners of garages are held responsible for the acts of their employees, for automobiles left in their care. William K. Krauss sued Albert B. Brightman for damages done to his car while stored in Brightman's garage when an employee drove it and sustained an accident.

No Cars—No Show

ATLANTA, GA., March 28—There was to be an automobile show here, but the dealers have sold all their cars and have none to exhibit.

Prosperity in Northwest

$40,000,000 in Deposits—Brisk Spring Trade Expected—Crop Conditions Good

NEW YORK CITY, April 3—Prosperity is shown in the reports from the Federal Reserve banks in the twelve regional districts. Business is flourishing despite the freight embargo and the growing cost of production. There is much activity in all retail lines and orders are overwhelming the manufacturers.

Excellent business conditions are reported from the Northwest. The public there seems to be guided by a spirit of common sense in its purchasing. Money is not being spent to an unwarranted degree for luxuries, although the better classes of goods are in demand. To a large degree the individual buyer is trying to get his money's worth—he has good purchasing power and is willing to spend his money.

Savings deposits in banks in the Northwest continue to increase and the spirit of thrift is becoming more evident. A new high record for deposits in Minneapolis is shown in the last comptroller's call for a statement from national banks. Present figures are slightly in excess of those of December, 1915, and illustrate a growth in deposits of nearly $40,000,000 since the March call of 1915. Loans and discounts for Minneapolis banks show a substantial increase over the December figures and a still greater increase over those of March a year ago.

Horses Slow Up Business

Roads in the country have been, in many cases, almost impassable for the last three weeks. In these days a very large percentage of country travel is by automobile, and when the breaking up of winter makes the roads bad for heavy motor transportation and the farmers have to depend upon horse-drawn vehicles, there is a very marked slowing up of business.

Every prospect is for brisk spring trade as soon as the roads are passable.

Reports from the territory to the south and west of that territory indicate good prospects for the coming crop. In the winter wheat belt the fields are apparently in good condition with plenty of moisture, although a recent storm will probably delay spring operations to some extent. Reports come from Iowa of general optimism and to some extent increased value for farm land, with some activity in the land market.

Large Sales Predicted for Norway

NEW YORK CITY, March 31—Prosperous conditions as a result of the European war will create a new outlet for American automobiles in Norway. V. E. Lindzen, of Lindzen & Robsahm, Christiania Hupmobile distributors, upon arriving in Detroit, stated that business in that country is better than ever before. Up to the start of the war most of the cars sold in that country were of German makes with a few Minervas from Belgium, Renaults from France and Daimlers from England. As these machines cannot now be secured, the dealers will naturally turn to the United States for their cars.

There are probably 2000 cars in Norway at present, and a large increase is expected in the near future.

Automobile Service Managers Want N. A. C. C. Help

DETROIT, MICH., April 4—Thirty members of the Automobile Service Managers' Assn. of Mich. were present at a smoker given by the organization at Hotel Statler on April 1. General service matters were discussed and it was the feeling that the service men must have the co-operation and help of the National Automobile Chamber of Commerce in promoting a standard service policy such as has been suggested by the association. Another meeting of the service men will be held on April 11 at the same place/ at which a standard repair parts policy will be discussed and acted upon. This will then be referred to the National Chamber with the hope that the latter organization will get behind it and seek to have it generally adopted. It is the general feeling that the meetings should be better attended and that all manufacturers should co-operate and take an interest in the work.

Edison Sales Organizations Meet

ORANGE, N. J., April 5—Salesmen and branch managers of the Edison Storage Battery Co. gathered at the factory and main office, Orange, recently for the annual sales meeting. H. G. Thompson, vice-president and general sales manager, presided. Those in attendance included: John Kelly, New York; W. F. Bauer, L. F. Meissner, H. J. Butler, Chicago; Bertram Smith, G. F. Simon, Detroit; E. M. Cutting, San Francisco; George W. Holden, Boston; C. H. Clare, New York; Geo. Drake Smith, E. J. Ross, Jr., H. H. Smith, F. V. McGinness, H. M. Roberts, H. W. Stortz, John Pulster, J. B. Renwick, Jr., R. C. Veale, A. Mudd, Geo. J. Glaser and Paul Sutcliffe, Orange.

Tire Shortage in Sweden

NEW YORK CITY, March 31—The automobile business at Sweden has been brought to a standstill by the war, according to Willy Schroeder, a representative of a Swedish tire company. Owners of cars stuff old tires with rags.

Factory Miscellany

Champion Ignition Adds—The Champion Ignition Co., Flint, Mich., has announced that work will be begun soon on a modern fireproof addition to its factory, which will add 12,500 ft. of floor space to the plant.

To Make Non-Skid Devices—T. O. Nelson of Fort Wayne, Ind., has gone to Goshen, Va., where he will make arrangements for the opening of a factory for the manufacture of automobile non-skidding devices and a new type of farm implement. The Virginia town has offered unusual inducements to obtain the factory.

Making Hearse Bodies—J. W. Henney, Jr., Freeport, has leased the Bloom Bldg., Hancock Avenue, East Freeport, and commenced the manufacture of hearse bodies for automobiles. He has for his associates several Chicago men who are well versed in body making for motors. Mr. Henney recently resigned his position with the Staver Auto Mfg. Co., Chicago, to take charge of the Freeport plant. He was for many years superintendent of the Henney branch of the Moline Plow Co. The new plant opened for business April 1.

Gardner Machine to Add—The Gardner Machine Co., Beloit, Wis., has awarded contracts for the erection of a 100 by 100 ft. machine shop addition and a new power house, 40 by 60 ft. The capacity will practically be doubled. The company has been working night and day for many months, and the addition will be rushed to give much-needed relief. The Berlin Machine Works, also of Beloit, which recently changed its name to P. B. Yates Machine Co., has awarded contracts for a new shop, 285 by 263 ft. The Yates company specializes in machinery for woodworking.

Inglis Succeeds Wallman—The Wallman Manufacturing Co., manufacturer of gasoline and oil storage systems, tanks and pumps, 283 Fifth Avenue, Milwaukee, Wis., has been succeeded by the Inglis Mfg. Co., a newly organized concern of which C. W. Inglis of the Milwaukee Steel Foundry Company is president and treasurer, and Charles Inglis, for 28 years past with the International Harvester Co., Milwaukee branch, is secretary and manager. It is the intention of the new concern to improve and largely increase the production of garage systems.

Gillette Safety Tire to Build—The Gillette Safety Tire Co., Eau Claire, Wis., has awarded contracts for the erection of its new factory, foundations for which were laid during the winter. The company was organized last fall by R. B. Gillette, an Eastern tire expert, and is spending about $75,000 in factory building and equipment. The main factory will be 60 by 250 ft. Work will begin at once and it is hoped to be able to start actual production by July 1.

To Invade Automobile Field—The Pulley-Grip Co., 405 Broadway, Milwaukee, Wis., which has been marketing a chemical compound for application to pulleys in factories and workshops to minimize belt slippage, is now putting out the preparation in a small size for use on fan and motor pulleys on pleasure and commercial cars. It is claimed that the use of Pulley-Grip will not only keep the fanbelt from slipping, but preserves the belt and saves bearings. The article is being used widely in all parts of the country by the largest manufacturers. It is stated that several truck and motor builders are equipping all belt-driven mechanisms with Pulley-Grip as standard equipment as a preventive of overheating on heavy-duty motors especially.

The Automobile Calendar

April 1-8	Butte, Mont., Home Industry Electric & Auto Show, Holland Arena, H. W. West, Mgr.
April 3-8	Twin Falls, Idaho, Show, Oliver Tabernacle, B. H. Fuller, Mgr.
April 8	Corona, Cal., 300-Mile Boulevard Race, Citrus Belt Racing Assn.
April 10-15	Seattle, Wash., Show, Arena.
April 10-15	Danville, Ill., Eastern Ill. Automobile and Electric Show; Chambers Bldg.
April 11-13	Milwaukee, Wis., Spring Show; Dealers' Show Room Automobile Display; Milwaukee Automobile Dealers.
April 12-15	Champaign, Ill., Show, Gymnasium Bldg., University, Ill.
April 14-16	Milwaukee, Wis., Garage-Circuit Exposition, Milwaukee Automobile Dealers.
April 15	Altoona, Pa., Pennsylvania State Motor Federation.
April 26-May 6	Oakland, Cal., First Annual Pacific Coast Motor Power and Automobile Show, Automobile Industries Assn.
May 6	Sioux City, Ia., Speedway Race, Sioux City Speedway Assn.
May 9-12	Hot Springs, Va., N. A. A. A. J. Meeting, The Homestead.
May 13	New York City, Sheepshead Bay Speedway Race. Metropolitan Trophy, 150 miles; Queens Cup, 50 miles; Coney Island Cup, 20 miles, and Brooklyn handicap for non-winners, 10 miles.
May 14-20	Milwaukee, Wis., Sheridan Road Week to Complete Highway Connecting Milwaukee and Chicago.
May 20	Chicago Non-Professional Speedway Race, Western Interclub Speedway Park.
May 26-27	Del Monte, Cal., Meeting, Three Divisions of National Assn. of Automobile Accessory Jobbers.
May 30	Des Moines, Ia., Iowa Derby, 20 Miles; Des Moines Special, 10 Miles.
May 30	Tacoma, Wash., 100-Mile Speedway Race, Tacoma Speedway Assn.
May 30	Indianapolis Speedway 300-Mile Race.
May 30	Minneapolis, Minn., Speedway Race.
June 10	Chicago Speedway Race. International 300-Mile Race, Speedway Park, Speedway Park Assn.
June 12-16	S. A. E. Summer Trip on Great Lakes.
June 20	Galesburg, Ill., Track Race, 100 miles.
June 28	Des Moines, Iowa, Speedway Free-for-all, 300-mile race.
July 2-6	Detroit, Mich., World's Salesmanship Congress, Detroit Board of Commerce Bldg.
July 4	Coeur d'Alene, Idaho, Race Meet. Hilles-Riegel.
July 4	Tacoma, Wash., Speedway Race, Tacoma Speedway Assn.
July 4	Minneapolis 300-Mile Speedway Race.
July 4	Sioux City Speedway Race.
July 15	Omaha, Neb., Speedway Race.
July 15	North Yakima, Wash., Track Race, Riegel-Hiller Co.
Aug. 5	Tacoma Speedway Race, Tacoma Speedway Assn.
Aug. 11-12	Pikes Peak, Col., Hill Climb, Pikes Peak Auto Highway Co.
Aug. 12	Portland, Ore., Track Race, Riegel-Hiller Co.
Aug. 18-19	Elgin Road Race.
Sept. 4	Des Moines Speedway Invitation Race. Limited to six entries.
Sept. 4	Indianapolis Speedway Race.
Sept. 4-5	Spokane, Wash., Track Race, Inland Auto Assn.
Sept. 11-16	Milwaukee, Wis., Fall Show, Wisconsin State Fair, Milwaukee Automobile Dealers.
Sept. 16	Providence Speedway Race.
Sept. 29	Trenton, N. J., Inter-State Fair. H. P. Murphy, Racing Sec.
Sept. 30	New York City, Sheepshead Bay Speedway Race.
Oct. 7	Philadelphia Speedway Race.
Oct. 7	Omaha Speedway Race.
Oct. 14	Chicago Speedway Race.
Oct. 19	Indianapolis, Ind., Race, Indianapolis Motor Speedway.
Nov.	Santa Monica, Cal., Vanderbilt Cup and Grand Prix Races.

The Week in the Industry

Boston Trade News—A. F. Chandler has been placed in charge of the retail sales for the Jackson Motor Co. of New England. He was formerly with the Willys-Overland and Paige-Detroit factories as traveling salesman, and later with the Becker Stutz Co. at Boston.

A. H. McIntyre, formerly with the Jackson company, is now with the wholesale department of the Saxon Motor Co.

Williamson Joins F. W. D.—G. H. Williamson of Cincinnati, formerly associated with the Maxwell Motor Co., Detroit, as district manager, has accepted a position in the sales department of the Four Wheel Drive Auto Co., Clintonville, Wis.

Milwaukee Items—The Wait Automobile Co., Fourth and Prairie Streets, Milwaukee, Wis., State distributer of Moline-Knight cars, has moved to new and larger quarters at 789-791 Thirty-second Street, and is occupying a modern, fireproof garage building, with ample repair-shop facilities.

John Wisniewski & Son, 904 Kinnickinnic Avenue, Milwaukee, have been appointed district agents for the Farmack Motor Co., Chicago, for Milwaukee and vicinity.

F. J. Siekert & Co., 326 Wells Street, Milwaukee, have been appointed agents for the Olsen wheel for Ford trucks and representatives of two large builders of delivery bodies for Ford chassis.

Washington Items—G. W. Miller, automobile dealer in Seattle, will shortly close out his stock of used cars at 715 East Pine Street, and following the trend of the times, will engage in the used parts business on East Pike Street.

Sharp and Leader of the Puget Sound Auto Co., Seattle, are now distributors of the Cole car in western Washington, which they will handle in addition to the Reo.

Another tire has made its appearance in Seattle, the Mohawk, distributed in Washington and Oregon by the Pacific Auto Supply Co. C. E. Barteau is president of the company in Seattle.

R. V. Barnett, field manager of the service department of the Mitchell-Lewis Motor Co., paid his annual visit to the Pacific Coast during the past month, visiting the Mitchell branches in California, Oregon and Washington. Reviewing the business, he said: "Conditions on the Pacific Coast, especially in the Northwest, were never better. Our sales to date are more than 100 per cent greater than last year."

Trade Happenings

Hartford Trade Changes—The A. C. Hine Co., Hartford, Conn., distributor in this State for Oakland, has put in an accessory department, giving up one-half of the salesroom at 314-316 Pearl Street for the purpose. W. J. Rabbitt, formerly with the Post & Lester Co., has been placed in charge. The Hine company has taken on the Knight tire for the State.

A deal is now in the works for the acquisition by the Willys-Overland Co. of a plot of ground at the corner of Asylum and Hurlburt Streets, Hartford, 90 by 140 ft., approximately. It is understood in automobile circles that the site will be used for a three-story service station and salesroom for Overland cars.

Andrew Caskey, at 26 Mechanic Street, Hartford, has taken on the Rayfield carburetor, formerly handled by the Palace Auto Service Co.

R. R. Ashwell, in the Ashwell service building, 341 Trumbull Street, has taken on the Norma ball-bearing and the Atwater Kent system of ignition.

Baltimore Trade Items—The Rawlings Implement Co., 11 West Pratt Street, Baltimore, Md., has taken over the distribution of the Federal tire.

The Mohawk Tire Sales Co., 1201 North Charles Street, Baltimore, has succeeded the Motor Car Accessory Co., and has taken over the stock, fixtures and good-will of the company. Mohawk tires will be a feature of the company's business. C. M. Ness of the firm of Charles M. Ness & Co., horse saddlery dealers, is president of the company, and G. T. Ness, vice-president. Frank Rowe is in charge of the sales and general management of the new company. Lerch Bros., Inc., 110 Hanover Street, Baltimore, has taken over the agency of the McGraw tires, a new line to Baltimore, and the firm will also distribute the McGraw product throughout the State.

H. C. Clark, 1014 Morton Street, Baltimore, has located at that address following the dissolution of the Motor Car Accessory Co. Several accessories, including Master Carburetor and Safety Vulcanizer, will be distributed throughout the State.

The United Auto Sales Co., a concern backed by several of Baltimore's leading men, has taken over the business of F. B. Donovan, Inc., and will handle the Studebaker line. The company will continue to maintain its office and showrooms in the Colonial Motor Car Bldg., 10 to 20 East North Avenue, and the service station will remain under their charge on Biddle Street, near Eutaw. Besides looking after Baltimore City, the new company will cover the territory in Baltimore, Harford, Howard, Anne Arundel and St. Mary's counties. Officers are: T. E. Straus, president; H. A. Mayer, vice-president and general manager, and W. E. Straus, secretary-treasurer.

Illinois News Items—A. Eisele, Rock Island, Ill., has purchased the stock of J. H. Bolte in the Union Motor Co., and will add a repair shop to the plant. He will be distributor of the Chevrolet car in Rock Island and adjoining counties.

The Modern Power Appliance Co., Rockford, Ill., was incorporated this week; capital stock, $5,000; incorporators, S. G. Smith, H. H. Rogers and W. D. Knight. Object, to manufacture and deal in automobiles, storage batteries and other supplies. A plant has been opened on North Main Street.

The Auto Starter Co., 168-172 North Halstead Street, Chicago, has been incorporated; capital stock, $2,500; incorporators, W. F. Millar, J. W. Diephouse and R. B. McKinney, to manufacture and deal in starters and other supplies for motor vehicles.

D. A. Heald and R. A. Snider, for a number of years mechanics with the Fisher & Raker garage, Canton, Ill., have decided to engage in business for themselves and have opened a new garage at 244 Van Buren Street, that city. They will carry a line of supplies and accessories in addition to a general repair business and battery and generator work.

Spokane, Wash., and Vicinity—The Foster-Larson Co., distributor for the Paige line in eastern Washington, has enjoyed an active business month during March. Jones and Smith closed for the agency for the Paige at Coulee City, Wash.; L. C. Densow took over the Paige agency at Krupp, Wash., and to the Enterprise Garage at Wilbur, Wash., went another Paige agency. The Ephrata Garage contracted for the same line at Ephrata, Wash.

Quaker tires have been introduced in Spokane by the McGowan Hardware Co., who have taken the agency for this line of tires for Spokane and the Inland Empire.

R. L. Strickle has been appointed secretary and treasurer of the Spokane Oldsmobile agency. Mr. Strickle was formerly of Winnipeg.

Industry's Elevator Service

Standardization Means Greater Efficiency at Lower Cost—Scientific Research Work Required More Urgently—Dimensional Standards Still Most Important—Many Standards Used Universally

By A. Ludlow Clayden

Chairman S. A. E. Standards Committee

THE why and wherefore of standardization; the enormous value of standardization to industry and to individual has been explained many times. No engineering body has ever done so much standardizing work in so short a space of time as the Society of Automobile Engineers, and this is all the more remarkable because automobile standards have been particularly hard to create.

This is because the sort of standardization which has been necessary in the automobile field apparently comes much closer to the individual engineer and to the ultimate user of the machine than does almost any other sort. *Apparently* only, because we have become so accustomed to the simpler standards that we cease to recognize them as such. The world would find life difficult indeed without the standards of measurement, without pounds, feet and gallons. If every merchant had his own standards for these things, so that a pound was sometimes six ounces and sometimes sixty, a foot anything from three inches to a yard, it is easy to see the awful confusion that would ensue. So it is with many other things, and we are floundering in all kinds of confusion to-day simply because we do not realize that it *is* confusion.

Dipping into history it is shown that it was the presence of confusion and the realization of its existence that caused governments throughout the world to step in and establish standards of weight and measurement by enactment. The realization of the confusion led to its elimination. The process began far earlier than we have any record; there are traces of it in the dimly distant past of Egypt; the Phoenicians spread their system over wide tracts of the earth. Thus we have no record as to whether the first man who suggested standards was, or was not, regarded as insane.

Most Standards Are Modern

It is a surprisingly short time since the weight, measure and money standards used in Europe were really well applied, and the engineering standards that exist are quite modern. The U. S. standard screw thread and the British Whitworth standard thread are examples of early engineering standardization by legislation, but we still see three or four different wire gages in use, and it is only the world of science that has shown itself advanced enough to adopt a universal standard of weight and measure. The advance of democracy must eventually break down the absurdity of national boundaries to such things as this. That Continental Europe, Great Britain and America should employ three different systems is almost as ridiculous as though New York and Pennsylvania were each to set up standards of their own invention.

Governments move slowly and they are only just commencing to take engineering standardization seriously in hand. Meanwhile engineers are developing standards which they use by agreement, some, but not all of which, will become subjects for enactment in the course of time. It is not all standards that are suitable for legislation like weights and measures.

Essentials of a Standard

Standards divide into two main classes, scientific or fundamental standards and standards of custom or convenience, which are usually "dimensional" in nature. Thus weights and measures are standards of custom; there is no reason for the choice of any special unit; a convenient unit is taken and all the scheme of weight or measure erected upon it. Standard screw threads are a different matter. Here the desire is to choose a thread such that the strength of the thread and of the bolt will be equal quantities, which means that there is a fundamental reason for choosing definite dimensions.

Coming to automobile standardization we find that most of it existing is dimensional; the S. A. E. standards are mainly standards of custom and convenience. The S. A. E. standards:

1. Facilitate production.
2. Increase efficiency.
3. Decrease price.

These are the three essentials of a standard; if it does not do one or more of these three then it is a poor standard and of no value whatever.

Detail Requirements

Let us examine these three requirements in detail. To facilitate production, increase efficiency and decrease price is to increase the ease of buying, or, in the ultimate, to increase the ease of manufacture. A typical example of this sort of standard requirement is the case of carbureter flanges.

Originally each automobile engine designer when producing a new engine laid out what seemed to him

a good flange on the side of the cylinder block or the end of the manifold for the attachment of the carbureter. Without doubt all the hundreds of flanges thus designed were perfectly satisfactory; they all gave enough area for proper compression of the gasket; they all had provision for studs or bolts large enough to enable a tight joint to be made. Carbureter makers, however, had to make their instruments with a flange to suit every engine. Often when three or four engine makers wanted the same size of carbureter they also asked for each a different flange, slightly different only, as a rule, but different enough to force the carbureter maker to have special tools, special jigs and even special carbureter body castings for each customer. Nobody obtained any benefit from this state of affairs except the tool maker, and every carbureter produced cost just a few cents more because of the greater amount of money tied up in tool equipment.

So was it with the sizes of steel tubes, so with lock washers, so with the specifications for steel and many other things. The S. A. E. took the ideas of all the engineers, made comparison between them, and rearranged them in a proper series which would satisfy all requirements.

An Elevator Service

The difference between the situation before and after S. A. E. standardization may be visualized as the difference between a flight of steps and an elevator. In a building of twenty floors somebody wants to get to each floor, but nobody wants to stand halfway between two stories. The S. A. E. put in an elevator which would stop twenty times and cut out the necessity for 500 stairs, and nobody had any use for the stairs from that time on. Thus in creat-

ing standards all that is necessary is to make sure that the elevator misses no floor and does not stop between any of them.

Now, the carbureter flange standard, the steel specification standards, the lock washer standards and many others were found by examining what was being done and then finding a series which would give the same results with fewer detail variations. These are standards based on practice or empirical standards.

Heavy Work Ahead

There are other matters which the S. A. E. has to consider which are more closely allied to the screw thread standard, in that they have but small reference to practice and are principally dependent upon fundamental principles. As time goes on the dimensional standards will become matter of course. It was necessary for the originators of the idea to prove that there was advantage in having a standard series of carbureter flanges, but there is no need to argue about the advantages of a standard speedometer drive connection or about the desirability of standard mountings for electric generators or starting motors.

Leads to the Laboratory

Thus the development of standardization work by the S. A. E., or any other engineering society, for that matter, leads inevitably to the laboratory, to the setting up of fundamental standards based upon scientific first principles.

Of such subjects the most important at present in hand is the question of lamp design. It is known that some headlights give good light with little glare, some give good light with much glare, some give little light with too much glare. To take all the lamps on the market and strike an average of their

optical dimensions would be useless. It would result in the production of a series of lamps of indifferent lighting quality and would certainly not increase efficiency, even if it decreased cost a little and facilitated production. Thus empirical standardization in this matter of lighting would not fill all three requirements and would not be of much value.

Accuracy Most Important

To get a standard that will be of use, necessitates careful laboratory work to decide, in exact terms, the effect of varying proportions in the filament of the bulb, in the curvature of the reflector, in the relation between the two, and so on. It is a far more difficult proposition than the empirical standard. First the tests must determine the ideals, and then investigation must show how close to those ideals we can get.

Another question now being considered which is of a similar nature is that of standard sizes for the drills to be used previous to tapping. Science calls for a perfect standard thread and practice cannot give it. Careful experiment is needed to determine the size of drill that will give the best thread in different materials so, though this is not theoretical work, it is work where the average of practice as it exists may have little relation to what that practice ought to be.

There are very many other things of a similar sort and, as the society grows in strength and in wealth, more and more of them will be taken up. In passing it may be remarked that the British Institution of Automobile Engineers has just commenced an investigation of steel standards for British use which will absorb a $10,000 grant from the British manufacturers' association.

The dimensional standards, however, remain the most important at present before the Standards

Committee, for dimensional work based on existing practice is well advanced, while the scientific procedure is but beginning. There are now in hand fifty different things on which work is being done actively, and another fifty concerning which information is being collected. Outside this formidable list there are many other subjects that have been suggested and are not yet taken up; in fact, each day almost brings some new standardization proposal to the S. A. E. office.

24,000 Hours of Work

To-day the Standards Committee has 120 members and thirteen divisions; each member puts in an average of well over 50 hr. a year in division meetings, added to which are the general meetings of the Standards Committee and of the society as a whole. Thus the total of time given per year by each member of the committee is not less than 100 hr. The division chairmen and members entrusted with research work give much more time than this. Multiplying 100 by 120 gives a grand total of 12,000 hr. of work, and allowing for the special work done outside the meetings, for the work of the honorary officials and that of the staff of the society, this total will certainly not be less than doubled. Eight into 24,000 goes 3000 times, which means that the Standards Committee members do as many hours of work in a year as one man could do in 10 years working in a regular way.

The S. A. E. has lately been collecting information from the industry as to the actual application of the S. A. E. standards. A request was made to a number of manufacturers that they would state which of the long list of standards were employed in their products. The first results of the canvass appear on pages 666 to 669 and are worthy of special study. One or two points, however, must not be overlooked in reading this tabulation properly. First, it must be remembered that all of the standards cannot apply to one product; a passenger car does not use solid rubber tires, for example, nor does a transmission manufacturer require spark plugs. Secondly, it has been shown that several of the firms who appear to be making less extensive usage of the standards do not really know how many standards they employ. Some of the car assemblers, for example, are not fully informed as to the standards employed in making the transmissions or motors which are fitted to their chassis.

Wide Use of Standards Encouraging

On the other hand, the very wide use of standards by firms making complete vehicles is very striking. In some ways standardization is likely to be more valuable to the assembler than to the manufacturer of complete cars, or would seem so to be, but a glance at these records shows that this view is a wrong one. Another interesting thing is to follow the horizontal lines and see thereby the universality of many standards. There is no need to specify them here; the table itself gives sufficient conspicuousness to each.

Standardization began in a small way with the S. A. E. and ever since it has been the aim of every man who came into direct contact with the work to do his best to help speed up. The more that is done the more there remains to do.

Automobile Electricity

Locating and Curing Troubles

Part II

Tracing Trouble in the Starting and Lighting System by Symptoms—Short Cuts in the Process of Elimination by Noting Superficial Indications

By J. Edward Schipper

TO detect electrical troubles the infallible rule is:
First—Study the symptoms.
Second—Make the diagnosis.

Since the starting and lighting systems can each be regarded as independent two main divisions are immediately suggested. They are:

A—Troubles in the lighting system.
B—Troubles in the starting system.

Improper Lighting Operation

Improper lighting operation is indicated in three ways:
Case 1—Engine stopped—lights out or dim.
Case 2—Engine running—lights out or dim.
Case 3—Some lamps bright—others dim or out.

CASE 1—Taking up Case 1 with engine stopped and lights out or dim there are two possibilities: A—Battery discharge due to some failure in the battery circuit or in the battery itself or, B—Open circuits in the wiring system.

A-Battery Discharge

Battery discharge as a symptom immediately suggests short circuit. This may be in the wiring of the lamps and their fittings, in the battery, in the circuit breaking or regulating mechanism or in a grounded generator. In fact, almost any part of this circuit is susceptible.

Lamp Shorts—The connections at the lamps sometimes give short-circuits due to poor taping causing bare wires to touch each other. Other things to look for in the lamp connections are loose strands of multi-strand wire bridging across the lamp terminals, grounding of the lamp sockets on the reflector or other lamp parts, defective sockets or other bare wires touching parts of the lamps due to chafing against the lamp or bad insulation.

Switch Shorts—At the lighting and starting switches grounds may be due to bad connections at the switch or a defective switch. Short-circuits at connections in the switch come from bare wires which touch each other, loose strands in multi-strand wires bridging across the terminals, or bare wires touching parts of the switch. Defective switches may have short-circuits in the working parts or through some condition of construction or mounting may be grounded.

Connector Shorts—Short-circuits in the connectors can be traced to either faulty wiring connection or defective connectors. The faulty wiring may have allowed bare wires of opposite sign (*i.e.* plus or minus) in contact, loose strands of wire across terminals or wire connections in contact with metal frame or body giving either a short or ground. Defective connectors have an internal short-circuit which can be readily detected by substituting a perfect connector.

Wire Shorts—Defects in the wire itself are due to bare wire caused by rotted insulation, worn insulation or poor connections. Where wire passes through metal parts the chafing must be noted. A ground to metal parts of the car may be due to worn or rotted insulation or by some metallic connection cutting through the wire insulation.

Battery Shorts—Battery short-circuits may be internal or external. If they are internal the battery itself may be worn out, the plates warped or buckled or a collection of sediment at the bottom of cells due to disintegrating plates although the latter is rare because of the height of the plates above bottom of jar.

External battery short-circuits may be due to acid on the top of the battery forming an electrolyte between terminals; battery terminals sulphated or in contact with top of metal battery box or battery wire connections acid soaked.

Circuit-Breaker Shorts—Circuit-breaker short-circuits may be due to the contacts being held closed by reason of being dirty or worn by a reversal of generator or battery wire connections or by a kick-back of the engine. The circuit-breaker might be grounded also due to defective insulation. A circuit-breaker short allows current to discharge battery through generator at less than charging speeds. After a long run at high speed lights would operate.

Synopsis

Part I—Last Week

¶ *Three fundamental thoughts were established in the first part of this electrical series.*

¶ *First: Continuity of which the circle is the symbol. Electricity flows in a circle or circuit. The circle must be complete.*

¶ *Second: The basic law of current flow. In order that this should exist there must be sufficient voltage.*

¶ *Third: Trouble testing by elimination. The electric circles are divided into a number of arcs by bridging across and these arcs are gone over one by one. These three principles are applied to the lighting, starting and ignition circles.*

Part II—This Week

¶ *Finding trouble by symptoms in starting and lighting systems. Classifying these and indicating the possible troubles for each set of symptoms.*

Part III—Next Week

¶ *Locating troubles by units in starting and lighting. Knowing the unit in which the trouble exists, the possible locations and causes are given in detail.*

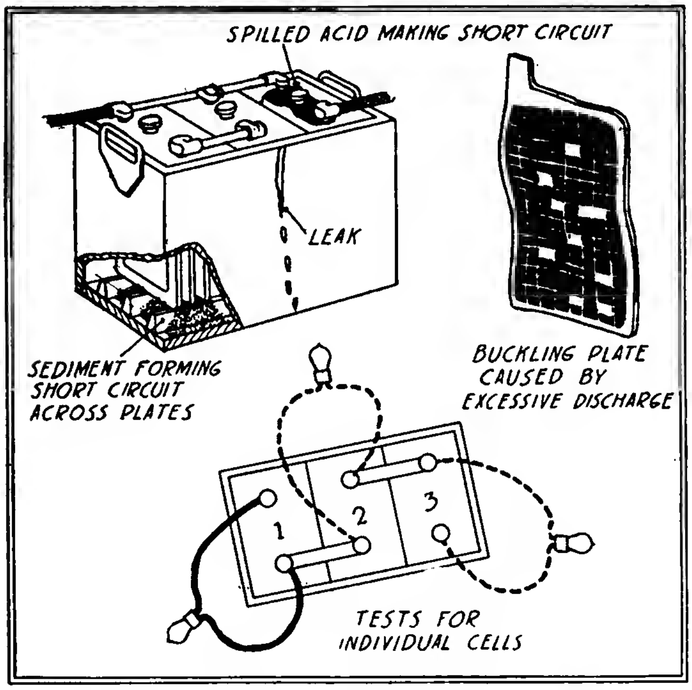

Fig. 1—Some common battery troubles and a simple battery test

A grounded generator can be caused by an accumulation of dust worn from the brushes or a defective insulation of the armature or field coils, located by examination.

A discharged battery can also be due to an overload on the starting or lighting system which may be caused by the leakage of current from short-circuits or grounds as described, by increasing the lamp load through the adding of higher candlepower or lower efficiency lamps, by adding additional apparatus to the lighting system, by the improper operation of the starting motor or by burning the lamps much longer than normal. A discharged battery can also be due to mishandling in winter storage or injured plates or cracked cells.

B—Open Circuits

Open circuits are caused by some breakage of wire or contact throughout the current path. They form a break in the electric circle. Loose connections or sulphated battery terminals should be looked for first. Points especially to be noted are switch terminals, lamp connector terminals and lamp sockets. Burned-out unscrewed bulbs are the most common open-circuit troubles. In connectors look for dirty contact points or no tension in the plunger springs. Bulb bases may not make good contact in lamp sockets or in the switch poor contact may be made. Broken wire at points subject to vibration or where joints have been made is a common open circuit trouble. When the points separate in a contact breaker a wilful open circuit is made. When they will not close at charging speed it should be remedied.

Engine Running, Lights Out or Dim

CASE 2—With the engine running a common ground of trouble with the conditions that obtain when the engine is stopped is in short-circuits. These should be traced in the same manner as outlined above.

Troubles in the Generator

Generator troubles fall under this general head and for this reason it is created. They may be classified under the following heads. Mechanical, field magnets weak, armature winding, commutator brushes and holders, governor, circuit-breaker and regulator.

Mechanical—Under the mechanical head the commutator may be omitted as it is discussed separately. The first cause of trouble is in faulty lubrication which has caused worn bearings allowing, frequently, the armature to strike against the pole pieces. The other cause of trouble is over-lubrication which generally results in rotted brush lead insulation causing a short-circuit or ground at the commutator. Other troubles are electrical, broadly speaking, as well as mechanical.

Fields—Weak field magnets will vary in cause according to whether the magnets are permanent or wound. In permanent magnets the cause is generally due to exhaustion through long use, no keeper used when removing them or magnets reversed when re-assembled. In wound magnets shunt field coil or coils may be grounded due to a water-soaked generator or short-circuited through burning out by running the generator with the battery disconnected. They may also be water-soaked or oil-soaked.

Armature—Armature windings may be burned out or grounded. When burnt out the trouble may be due to a current overload due to improper regulation, a soaked winding or a steady and prolonged return flow from the battery due to failure of the circuit breaker contact points in opening. A grounded armature winding is due to defective insulation.

Commutator—Commutator troubles can be divided into two heads. First, those due to defective manufacture and those due to surface wear or deterioration in service. Defective commutators may be grounded, have a short-circuit between their segments or have loose segments and are generally denoted by sparking at the brushes. Those that have deteriorated in service show a rough or blackened surface due to the following causes: Sparking from worn or short brushes, sparking on account of high mica, cheap brushes, oil collection on commutator surface, loose copper segments, poor contact between brushes and commutator generally due to sticking holders, or poor contact due to weak brush spring pressure.

Brushes—Faults in brushes and brush holders can be classified into five divisions, namely, grounded, poor spring tension, sticking in holder, poor fit to commutator surface and over-heating holders. When grounded it is due to de-

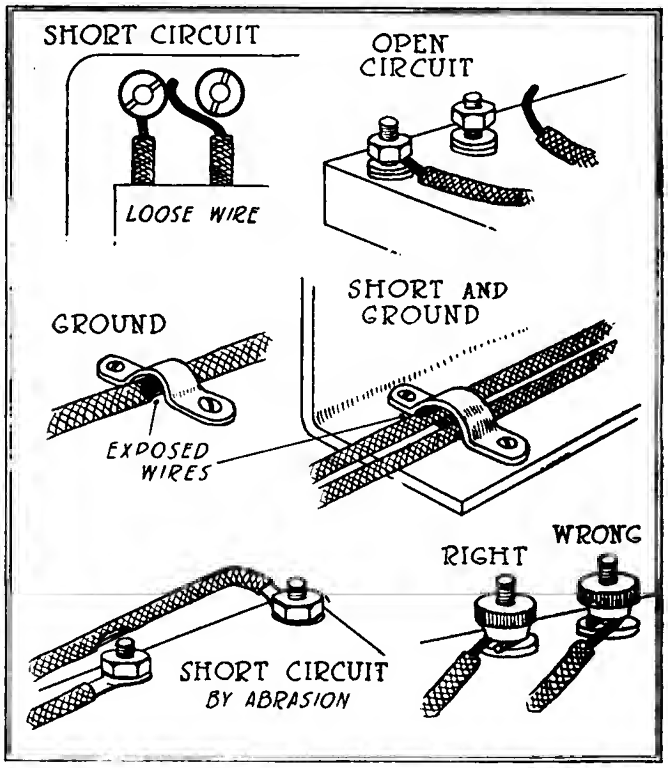

Fig. 2—Typical examples of short and open circuits and grounds

fective insulation or dust deposit. When spring tension fails the brushes are worn too short, the tension is not adjusted or has been thrown out due to heat, or the springs themselves may be broken. When the brushes stick it may be due to binding or from dirt and grease. When the brushes do not fit the commutator surface it is a matter of manufacture. Over-heating brush holders are caused by the sparking of poor brushes or no brush lead connection.

Governor—Generators which have a slipping clutch or governor form of regulation may have troubles in the governor due to a mechanical break, disintegration of weights where lead or other soft metal is used, or a defect between the brake shoes and drum due to a collection of grease or a worn shoe.

Circuit-Breaker—In the circuit-breaker or main contact, as it is often called, there may be a direct mechanical break, a burned-out coil due to current overload or a ground due to defective insulation, a bad adjustment which does not allow the generator to cut in at all or if so at an improper speed or the contact points may be sticking. The latter is due to a mechanical break, disintegration of weights where worn out or dirty contact points, reversed wires at the generator terminal or a backfire of the engine.

Open Circuits with Motor Running

Again under the main head of no lights or dim lights, with the engine running, there is a group of troubles which can be classified under the general head of open circuits. There are eleven of these which are prominent: 1—The generator terminal connections may be loose or making poor contact; 2—The wire connections to the switch may be defective; 3—Defective wire connections to connector terminals; 4—Lamp socket terminals disconnected or loose; 5—Burned-out bulbs; 6—Halves of connectors do not make contact; 7—Bulb bases out of contact with lamp sockets; 8—No connection between lighting switch terminals; 9—Broken wires especially at taps; 10—Joints or places subject to abrasion and 11—Defective connections at the lamp sockets.

Some Lamps Bright Others Out or Dim

CASE 3—Local troubles under the general head of lights dim or out when engine not running, should be first sought for in a partly-discharged battery. When the engine is running, in addition to the partly-discharged battery the circuit-breaker or generator troubles above outlined should be drawn over. If one or more lamps are unsteady and flicker the circuit-breaker troubles should be gone through, the lamp filament may be broken making and breaking contact or a poor contact in the lighting switch, connectors or lamp sockets. With some of the lamps bright and others dim, the circuit on the dim lamps may have a partial short or the troubles explained above for switches, connectors and lamp sockets should be gone through. In single wire installations a ground should be searched for; the bulbs showing dim may be intended for higher voltage, or the bulb may be blackened due to being nearly burned out.

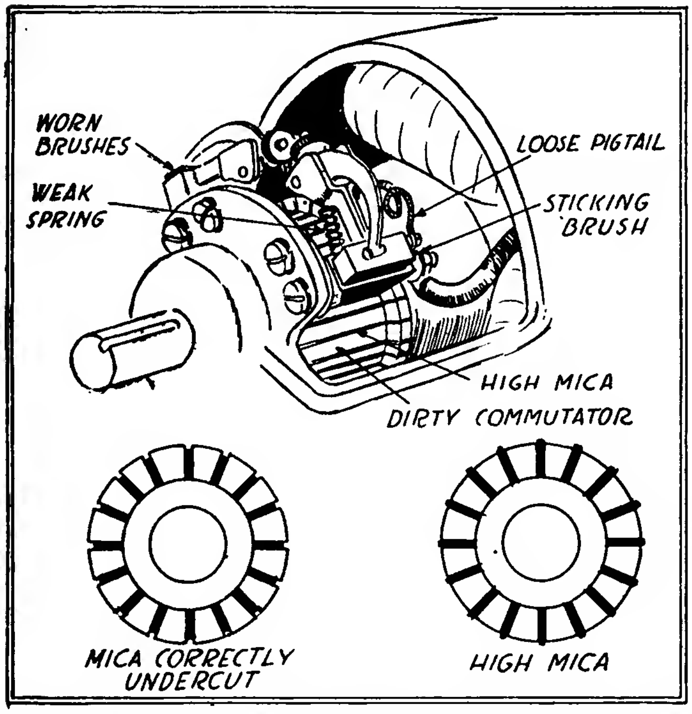

Fig. 3—The commutator assembly and some of its common troubles

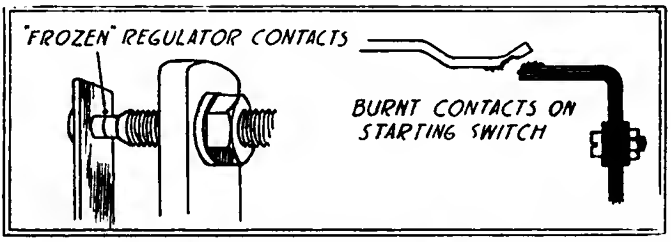

Fig. 4—Two troubles which are not infrequent in lighting and starting systems

Starting Troubles

TROUBLES in the starting system are indicated in two ways: First, the starter will not crank the engine at all, or second, it cranks it so slowly that proper starting is not given. The first thought in either of these cases is that the battery may be partly or completely discharged or it may be operating at very low efficiency due to very cold weather or some other cause.

Coming back to the general head of when the starting motor will not crank the engine at all there are two causes, open circuits and short-circuits or grounds.

Open Starting Circuits

Open circuits on the cranking motor will be found at the brushes, in loose connections at the commutator starting switch or in the wiring. If at the brushes they may be worn too short or improperly adjusted. They may also stick in the holders due to binding or dirt. Loose connections are obvious, the commutator troubles are the same as those described for generators, the starting switch trouble is nearly always a failure of switch blades to make contact. Sometimes the switches are fused owing to arcing.

Shorts in Starting Circle

Under the head of short-circuits and grounds, these can be divided under the general heads of those in the armature, those in the wiring and those at the starting switch. In the armature or field winding of the motor these may be either burned out or grounded. In the wiring a short-circuit may exist due to rotted or worn insulation or a ground from rotted or worn insulation or from metal screw or cleat connections which cut through the insulation making a ground to one of the metal parts of the car. In the starting switch either a ground or short-circuit may be found due to water soaking or otherwise defective insulation.

Starting Motor Cranks Too Slowly

After the battery condition has been looked after and the starting switch examined for poor contact, the remaining source of trouble is due to a drop in potential caused by a high resistance in the starting circuit. The brushes may not fit the commutator or have proper spring tension or may be poor, giving high resistance. The brush leads may also give poor contact. The same commutator troubles applying to the generator may exist or there may be loose connections in the starting motor wiring which can be sub-divided under the same general heads as the generator troubles.

Shall the Differential Be Abandoned?

Experiments on Trucks and Passenger Cars Show That Eliminating the Balance Gear Is Beneficial in Several Respects—Comparative Tests To Prove the Case

By A. Ludlow Clayden

THE necessity for a differential to allow a corner to be turned without slipping either of the driving wheels has only recently been questioned with respect to automobiles, although street cars and locomotives have always been made with plain, solid driving axles. To-day it seems possible that we have for years been laboring under a delusion, in so far that experiments are showing vehicles without differentials to possess certain distinct advantages.

In 1913 automobile engineers were much interested by the elimination of the differential from the Sunbeam racing cars, and in the races of that year in Europe these machines showed a good tire economy, while the drivers commented upon the remarkably steady steering at high speeds. In 1914 the Sunbeam company abandoned the scheme, giving as the reason the fact that a blowout at high speed on a rear wheel made the steering hard, was actually dangerous in fact.

Meanwhile several small cars appeared on the European market without differentials, notably the Mathis designed partly by E. Bugatti, and the baby Charron. These little cars proved just about the same from the viewpoint of tire wear as though they had the differential, they exhibited slightly less tendency to skid when driving, and much less when braking, while they were exceptionally easy to steer at speeds of 50 m.p.h. Moreover, a blowout did not seem to disturb the steering within the speed range of which the little cars were capable. The most prominent disadvantages were that care had to be taken to use identical tires on both rear wheels, since if one were a trifle larger than the other the tread soon became rough and chafed on the larger casing; and that the cars were difficult to push by hand except in a straight direction. With little cars usually kept in cramped quarters this was a real disadvantage to many owners.

At the outbreak of war this no-differential experiment in the light car world was being watched with great interest, but, of course, nothing has been done since August, 1914.

Truck Tests Made in America

During the past year in America experiments have been made beginning at the other end of the scale, on a series of large motor trucks instead of on light cars. Also there are on the market several substitutes for the differential gear designed to limit the extreme freedom of action which is the differential's worst fault. The most instructive of the tests are those now being made by the Fifth Avenue Coach Co. on several of the buses which are running on routes in New York City, these tests having been commenced at the instigation of A. M. Laycock, chief engineer of the Sheldon Axle & Spring Co.

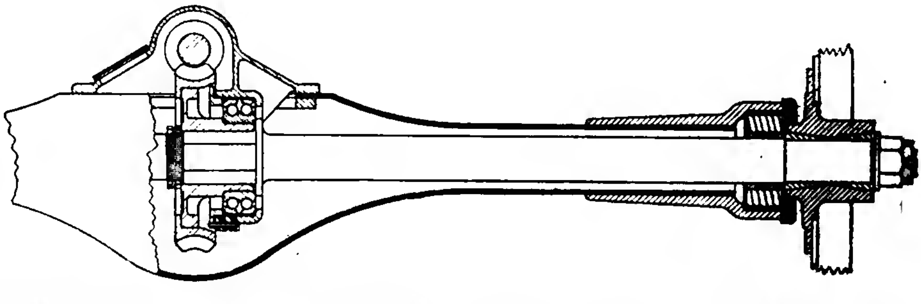
Last fall the differential gear was taken out of one of the buses, the two halves of the casing being locked together, and care was taken to preserve this as a strict secret, none of the drivers being informed.

Concerning the performance of the bus the chief engineer of the company, G. A. Green, reports two things of special importance. The first is that the bus was not troubled in any way by the winter snows, though these caused considerable delay and difficulty with many others, and the second is that the wear on the tires appears to be less than normal. Since the differential was removed the distance run is well over 31,000 miles and the original rear tires lasted 15,495 and 16,000 miles respectively. At the time of their removal they were still a little over half an inch larger in diameter than the limit, there being 1¼ in. of rubber left instead of ⅞ in. This mileage compares well with the average for the buses, as that is about 11,000 miles, but Mr. Green points out that the results are inconclusive because such large variations are noticed in tire durability. He considers it will be necessary to wear out six or seven sets of tires before the tire wear can be estimated properly. It is, however, some small confirmation of the durability shown in the first set, to learn that the second pair of tires are still in operation and are approaching the mileage given by the first pair.

As regards liability to skid this seems to be about the same, except when braking, when it is less, and the only comment the driver had to make of an adverse nature was that the bus seems sluggish on making sharp turns, requiring more throttle opening than usual. Several other buses are now being converted and will be run throughout the present year, Mr. Green hoping to decide the matter completely by next winter.

The most attractive feature of a differentialless axle from the engineer's viewpoint is the opportunity it affords for saving weight. In the experiments made thus far, ordinary axles have been used with the differentials filled with lead, or with the drive shafts taken out and a single shaft, solid from end to end, inserted in their place. If designing an axle to operate without a differential, however, it would be possible to use a shaft strong enough to carry the weight as well as taking the drive, which would mean that the casing for the worm gear would only need to be strong enough to support the driving stresses and would have no weight-carrying function.

In addition to the bus experiments, the Sheldon company has sent out a number of axles without differentials to different parts of the country, and is getting most encourag-



Sheldon worm driven axle with single solid drive shaft replacing the original differential ing reports from the Middle West and parts where trucks are used largely on sand roads. In loose gravel the absence of the differential may easily make all the difference between ability to proceed and complete stalling. The results of these experiments are also being watched with care, so that much valuable data should be available in a few months.

At first thought the idea of removing the differential sounds absurd, and the first anticipation is that the chafing action on the tires would be very bad, but when the matter is examined in detail the question of tire wear is easily explained.

Slip on Sharpest Turn

For example: The sharpest turn made by an automobile in service is of about 20 ft. radius, and very few turns are made as sharp as this, the majority of deviations from the straight line being of 100 ft. or more in radius. Taking the extreme case, imagine a vehicle with 34-in. tires making a turn at 20 ft. radius. Turning through a right angle the inner wheel will be 20 ft. from the center of turning and the outer wheel 24 ft. 8 in., so the distance traveled by the inner wheel in making the turn will be 15.7 ft. and that covered by the outer wheel 19.3 ft. Now the 34-in. wheel covering these distances will, if rolling freely, make 1.76 and 2.16 revolutions, the difference being 0.4 revolution. It is still a moot point as to which wheel does most of the slipping, under these circumstances, but it is safe to assume that it will be mainly the inner wheel. This slipping, of course, causes some wear.

Action When Braking

Turning to the other case, where a differential is fitted, it is not possible to calculate the slip, but every time a rear wheel passes over a bump and so leaves the road for an instant it is slightly accelerated and is slowed down again by friction when it returns to the road. The amount of acceleration is very small, but what makes the big difference is that the slipping caused in this way is going on during the whole time the vehicle is running, whether straight or on turns, whereas the solid axle causes slipping on turns only and prevents the acceleration effect. If one wheel is off the ground, the other being in contact with it maintains the speed of revolution of both wheels constant.

The reason that the solid axle reduces the tendency to skid when braking is that either rear wheel must continue revolving if the other is turning. If one wheel rests on a wet patch and the other is on dry road, that on the wet can be made to lock by a light application of the brake. Directly a wheel ceases to revolve and begins to slide it is useless for controlling the direction of the vehicle, it merely takes the path along the road which offers the least resistance, and variations in the condition of the surface cause the locked wheel to try to follow a tortuous path. If the other wheel is locked also the rear end of the vehicle will have no sense of direction, whether the axle has a differential or whether it has not. When one wheel is locked and the other, being on dry road, is not locked, then the latter is liable to be pulled out of its path by the gyrations of the former, but when both turn together, at the same speed, as they must do with the solid axle, then both keep their sense of direction and maintain the straight course. It is easy to see why the solid axle enables snow or sand to be taken without trouble, and the braking question is merely a reversal of the same argument.

The ideal, of course, all other things being equal, is to have a differential for making sharp turns and not to have one for 99 per cent of normal running. Thus there is a great deal to be said for a modified mechanism which will strike a mean between the two extremes. Whether the solid axle, or a modified differential comes to be accepted practice, or whether the old differential will emerge from the time of trial in unaltered form is a matter for speculation, but it appears that 1916 will stand out in automobile engineering as the year when the differential question was settled.

Improving on the Cotter Pin

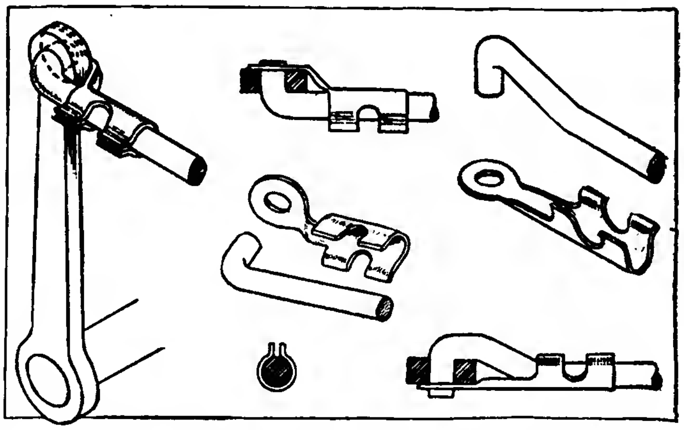
New Device for Securing Rod Ends Simpler and More Effective Than Old Method

It is seldom that any new invention affects the simpler mechanical devices. Only at rare intervals does anyone discover a better way of doing some very simple thing than the way that has been used for years. A novelty which will replace the cotter pin for many of its applications; which is more effective and no more costly is thus an invention of no small importance, as it cannot fail to find a scope of application far exceeding the automobile industry.

Such a device patented by C. S. Pelton of the Perfection Spring Co., Cleveland, Ohio, is now being put on the market by the Burns & Bassick Co., Bridgeport, Conn. Primarily the "Pelton clip" was designed to connect the throttle-operating rod to the throttle lever. The usual method is to bend over the end of the rod, drill it and place it through the lever hole, afterward putting in a cotter pin. The Pelton clip dispenses with the drilling, guards against rattle, is equally cheap and is easier of application.

The illustrations render the idea perfectly clear. The clip is made from sheet steel, punched from strip and with the tongues bent up into a nearly parallel position. To apply it, it is simply put in place and the ends of the tongues brought together with a pair of pliers. The end of the clip can be set to take a bearing against the throttle lever, so preventing rattle, and the clip is easily detached by opening the tongues with a screwdriver. As shown, there are two patterns, one with the clip bent out to clear the lever end, and the other, a straight clip for cases where the end of the rod is cranked.

Of course, the throttle application is far from being the only one. Throughout a chassis there are many other places where the Pelton clip is greatly the superior of a cotter pin, and in agricultural machinery there is an enormous field.



Pelton clip in straight and cranked form. Note the end view which shows lips which are closed by pliers or separated by screwdriver for detaching the clip.

Motor Trucks and Trailers Aid Mexican Expedition

The above illustrations give some idea of the thoroughness with which the army authorities have gone about securing sufficient motor transport for men and supplies on the punitive expedition of American troops pursuing the Mexican bandit Villa.

1—Enlisting men for the chauffeurs' division. Applicants are always more numerous than the positions to be filled. All are eager for a trial.

2—One of the heavier types of Troy trailer used for the more weighty supplies.

3—A Jeffery quad loaded with general supplies for the army at the front, rations, tents, ammunition, etc.

4—A new Jeffery quad stocking up with gasoline directly from the tank car.

5—Ford ambulance with two stretchers, one placed above the other on the side opposite the driver. This car also draws a trailer carrying two stretchers.

6—Twenty-three of twenty-eight Packard light service trucks ready for shipment fourteen hours after the second order was received from Washington for trucks for army service in Mexico.

Burman Killed in Corona Grand Prize

Car Overturns at 100 M.P.H.—Mechanic Killed—Others Injured

The late Robert Burman

CORONA, CAL., April 8—Robert Burman, celebrated as Wild Bob throughout the world as an automobile racing driver, was mortally injured and his mechanician, Eric Schrader, and a track policeman were killed here to-day when Burman's Peugeot blew out a tire at 100 m.p.h. in the ninety-seventh lap of the Corona Grand Prize. The car skidded upon a culvert and crashed past two telephone poles into a group of spectators, several of whom were seriously injured. Burman died at the Riverside Hospital at 5:55 this evening. His skull was fractured, several ribs were crushed and both legs broken in several places. Mrs. Burman was with her husband when he died, having rushed to the emergency hospital ahead of the ambulance that took him to the operating room.

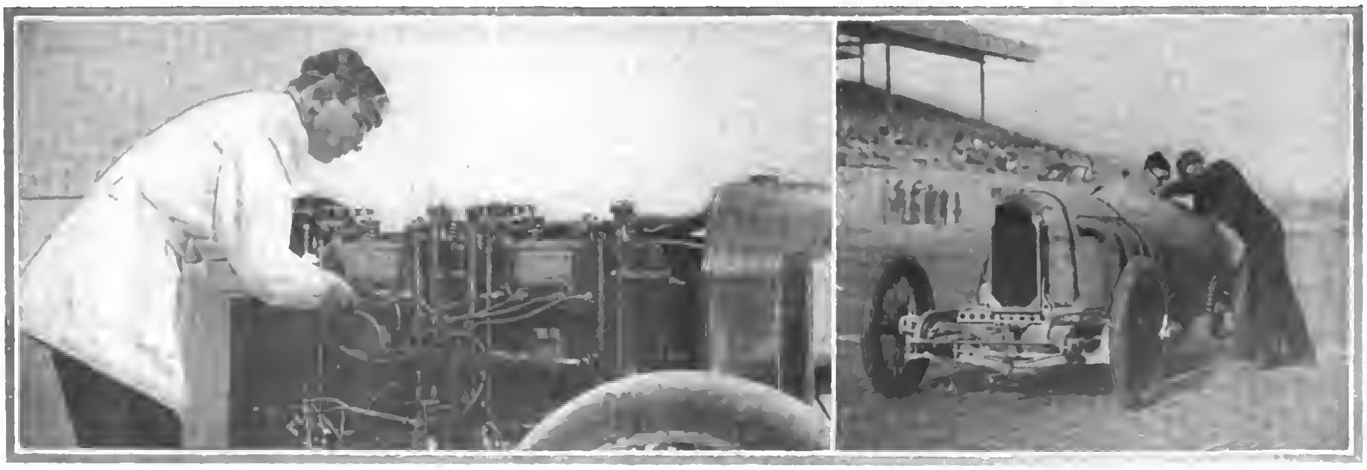
When the accident occurred Burman was six laps behind O'Donnell, who was leading, and was driving at top speed to make up some of the time he lost at the pits during his frequent stops for tire changes and mechanical troubles. Struggling under these handicaps, Burman drove with his characteristic fearless abandon now in first place, now in last and then back in the lead again, drawing frantic plaudits from the crowd as he forced his mount on, lap after lap, ever striving against adversity in his fight for first place and the $5,000 purse.

On March 25 Burman won the Exposition cup race at San Diego, Cal., sending his Peugeot over the 50-mile course at 52:14 m.p.h.

Burman, frequently characterized as the world's speed king, was born in Imlay City, Mich., April 22, 1884. Burman tested the first automobile ever manufactured by the Buick Motor Car Co. and then entered the employ of the Jackson Automobile Co., becoming head tester. While thus employed, a resident of Jackson, Mich., built a freak racing car and invited Burman to enter into a contest with him. This Burman did and won his race by more than a mile. This early success decided him to enter the racing field and he induced the Jackson company to allow him to enter one of their cars in a 50-mile race at Detroit in 1906. He won against a field comprising practically all of the leading racing drivers in the country. This was the beginning of his fame as a racing driver. His next experience was at St. Louis, where he drove twenty-two and one-half hours of a twenty-four-hour race, winning by 82 miles. With the Buick cars, which he drove later, Burman won so many races that he attracted attention all over the world. His most notable victory in 1910 was the winning of third place in the Grand Prize at Savannah, his car being the first American-built machine to cross the tape.

Burman held five records on the straightaway regardless of class. They are: 1 kilometer, 0:15.88; 1 mile, 0:25.40, and 2 miles, 0:51.28 made in his Blitzen Benz at Daytona, Fla.; the other two, made in the Buick Bug at Jacksonville, are: 20 miles, 13:11.92, and 50 miles, 35:52.31.

Burman also held the class B speedway record for stock cars of 301 to 450 cu. in. for 250 miles, 4:38:57.40. He held the quarter-mile speedway record made in his Benz at Indianapolis in 0:8.16; 1 kilometer in 0:21.40; ½ mile, 16.80; and 1 mile, 35.35. He also held six circular dirt track records, 10 miles, 8:16.40; 15 miles, 12:47; 20 miles, 16:25.60; 25 miles, 20:28.80; 50 miles, 40:57.80; and 75 miles, 1:08.56.



Two views of Burman. At the left he is tuning up his Blitzen Benz prior to breaking the world's record for the mile, and at the right as he was starting in the match race between his Benz and De Palma in the twelve-cylinder Sunbeam at the Sheepshead Bay Speedway on Nov. 2, 1915 in two heats, the average speed in one being 111.97 and in the other 113.86 m.p.h.

Essentials of Racing Engines

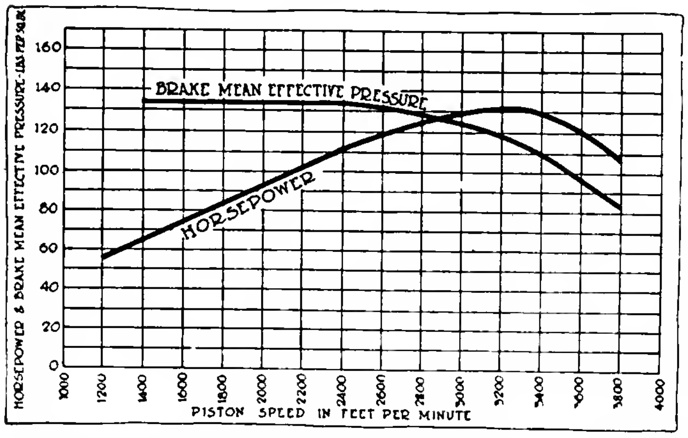
Intimate Engineering Details of Wisconsin Racing Motors Described and Discussed by Mid-West Section S. A. E at First Professional Session of Section

CHICAGO, ILL., April 8—Last night the first professional session of the Mid-West section of the S. A. E. took place, the paper of the evening being given by Charles H. John, president and general manager of the Wisconsin Motor Co., Milwaukee, Wis. Mr. John gave a general talk on the racing work done by his company, including the fullest details of the engines with which the Stutz cars were so remarkably successful last year. The paper is reprinted almost in full below. Some of the details mentioned by Mr. John were given in THE AUTOMOBILE for Oct. 14, 1915, but there is a good deal of additional information particularly as regards lubrication and valve gear.

Model Aeroplanes Make Flights

Another feature of the meeting which aroused equal enthusiasm was the exhibition of model aeroplanes by the Model Aeroplane Club of Illinois. Preliminary to the exhibition, Arthur Elton Nealy of the Model Aeroplane Club presented a short paper in which he brought out the value of the model aeroplanes in the development of aviation with particular reference to what the models were doing in the development of automatic stability in full size machines. He stated that at the present time the full size machine so far as its stability and guidance was concerned is 90 per cent operator, and 10 per cent machine, but that in the models which carry no operators, automatic stability and guidance must be inherent in order to make successful flights inasmuch as no operators, of course, can be carried in the midget aeroplanes.

In the demonstrations of the flying ability of the models which followed, Mr. Nealy succeeded in proving that model aeroplanes can be made to have a great degree of inherent stability and guiding power. About a dozen different types of models were flown within the confines of the assembly hall and the young men who manipulated seemed able to make them guide themselves with almost human intelligence. The models looped-the-loop and did similar stunts which have been featured by aviators. The most striking exhibition was that of a model hydroaeroplane which arose from a pan of water 2 ft. by 3 ft. in size, flew out over the audience, looped-the-loop and returned to rest in the pan.



Horsepower and brake mean effective pressure curves plotted against piston speed for Wisconsin racing engine.

Mr. John's paper follows:

In the high speed motor the underlying principle is to reduce the weight of the reciprocating parts to a minimum for safety. By reducing the weight of these parts the inertia forces are reduced, which are the causes of excessive vibration at high speeds and which waste much power by reason of the extra friction. This is accomplished by using better materials for the connecting rod and piston. Chrome vanadium connecting rods, heat treated, of exceedingly light weight, and pistons of special aluminum alloy, reduced the inertia forces to a minimum and greatly relieved the stresses upon the connecting rod as well as on the bearings. Alloy steels were also employed for the crankshafts, bolts, gears and other parts subjected to excessive strains. The microscope is used to determine the proper heat treatment and the scleroscope to get the proper hardness. Valve springs had to be made of vanadium steel and tungsten steel was developed for valves. Bearing metals are given special study, as under the great pressure and high speeds ordinary metal would burn out in a short time. The law of bearings, however, would prove inadequate without an efficient oiling system.

Racing, and naturally, also, high speed engines, have compelled the engineers to give the question of correct lubrication their minute attention. The result of their labors was the introduction of high grade motor oil, and this, to some extent, has eliminated a great many motor troubles. In these high speed motor tests it was also discovered that oils, when exposed to very high temperatures, would deposit a sediment in the oil chamber. This was largely eliminated by cooling fins in the piston, also cooling fins on the crank base. In a test made with one of the large Wisconsin six-cylinder tractor motors, we found that running the oil through cool water, which was made possible on account of our forced feed oiling system, increased the efficiency nearly 10 per cent. This taught us a valuable lesson, and we now are cooling the oil on our tractor motors by means of a jacketed inlet manifold. This manifold has double duties, to-wit: cools the oils and at the same time heats the incoming gases.

Lubrication Most Important

I attribute a great deal of the success of Wisconsin motors in racing annals to their perfect oiling system, which in all of our motors is the forced feed type. The oil is contained in a separate oil sump and is forced by a gear pump through ducts to the main bearings and then through holes bored in the crankshaft to the connecting rod bearings. The oil under pressure is forced from each side of the connecting rod bearings and is thrown in all directions. In this way oil is splashed against the cylinder walls, pistons, push rods and into pockets over the camshaft bearings. Oil is also fed directly over the timing gears by means of a copper tube leading from the main duct. The oil then drains back into the sump through a strainer and is there ready for another journey. This, in the opinion of many engineers, is the most efficient and economical oiling system yet introduced. In a 10-hr. continuous test recently made at our plant on a high-speed motor, the consumption of oil was slightly over 1/100 pint per hp. per hour.

Long Stroke Is Advantage

As the amount of power available from an engine depends upon the volume of gas consumed in a given time, it was evident that by using smaller cylinders and allowing the crankshaft to revolve faster, the same amount of power could be obtained as from a larger engine revolving at slower speeds. Extensive trials also proved that the long-stroke motor was capable of greater speed and increased power over the short-stroke motors. This lead to the development of the present 300 cu. in. racing motors which I will endeavor to describe more fully.

Selecting the Steel

It is hardly necessary for me to repeat the success of Harry Stutz on the speedway, in the road races and in the transcontinental runs. I wish to add, however, that all of the races up to the year 1915 were run with practically our stock T-head motors. Directly after the Indianapolis speedway races of 1914, we concluded that the foreign invaders had carried off enough of our good gold, and we agreed to build four motors for Mr. Stutz that could successfully compete with the foreign racing machines. Our engineer, A. F. Milbrath, had sketched out one of his ideas which met with Mr. Stutz's approval, and we immediately started to work on these motors. We had heard wonderful tales of a new steel made in Belgium, called B. N. D., with a wonderful tensile strength, and we concluded that we had to get this steel. Orders for crankshaft and connecting rod materials were placed at once, but alas, war was suddenly declared, and we were compelled to look for other channels of supply. We decided to use chrome-vanadium steel, which had given us such excellent service. This was of American make, and the greatest care was exercised in the selection of all materials. The scleroscope and the Brinell tests were resorted to, and in addition, to make sure that the material was correct, physical tests and chemical analyses were made. After heat treatment, specimens were taken from the various parts and examined micro-photographically to insure the granular structure being right. With these precautions, we were able to demonstrate that America can produce steel equal in strength and stability to anything produced abroad, and to-day American products are at a par with any of European extraction. Our tests convinced us that we had the proper material, so we rushed through a single motor in order to give it a thorough test.

Gives 131 B.H.P. at 2950 R.P.M.

When the first motor was completed and put on the test stands the results were quite satisfactory, but no extraordinary power or speed were developed. A careful study of lubrication and principally ignition was necessary before we were able to get results. When all of these difficulties had been satisfactorily solved, we obtained some very astonishing figures, in fact, they were far above our expectations. This motor of 296.81 cu. in. capacity developed 131 b.hp. at 2950 r.p.m., and was at once shipped to Mr. Stutz, whose chassis was ready for the motor, and trials were at once started. It was shown by these trials that this engine was developing extraordinary power, and Mr. Stutz at once notified us to proceed with the other motors. Three cars were built and the performance of these three cars has been among the most remarkable in automobile racing. In the 500-mile Decoration Day races at Indianapolis, these three cars started, and all three finished well up in the running, a record never equalled before.

I do not have to enumerate all the victories which Harry Stutz won, as they are matters of history. Foreign engineers have as a rule taken their defeat manfully, and are giving America due credit for designing and building a motor capable of such wonderful achievements.

American engineers have shown that they are equal to their European cousins, American car builders can build just as good a chassis and American steel makers can produce just as good materials, and perhaps better, than the famous steels of Belgium.

I-Head Is Efficient

It is well known that a gasoline poppet valve engine follows certain lines, and these lines are fixed and cannot be altered. The valve-in-the-head type has been recognized as the most efficient construction, and it is only a few years since the four-valve superseded the two-valve type. It is not necessary for me to argue the merits of the four-valve type, and neither do I wish to enter into a dispute as to the authorship of this type. I have read of an English engineer claiming he orginated this idea, and then again the French claim it, and so do the Italians. We also find that very nearly all of the European racing cars are using four valves, and I will just mention the Sunbeam, Humber, Straker-Squire, Vauxhall, Peugeot, Delage, Schneider, Mercedes, Isotta-Fraschini and Fiat.

Dispensed with Valve Cages

In all of these there is a certain similarity, especially in the combustion chamber, as it is necessary to employ the semi-spherical shape if one wants to obtain large valve area. It was also found necessary to dispense with valve cages, and so we find valves fitted directly in the cylinder head with ample waterjackets surrounding them. These essentials in motor construction were established, and it was now the ambition and aim of the automobile engineer to get the greatest amount of power out of a given cylinder volume for the greatest length of time. The fact is established that we took their own weapons and defeated them squarely, and we are proud of our record.

Aluminum Barrel Crankcase

It may be of interest to members of the section to hear the details of construction of this motor. The aluminum crankcase of the Wisconsin racing motor is of the barrel type, with rather a large opening on the bottom, but built extremely rigid. The bottom cover is provided with cooling ribs. The main bearings are ball-bearing, with 1-in. diameter balls, and held in place by means of cast steel retainers. The motor is three-point suspension, the forward end supported by a trunnion bearing on the steel front cover plate and the rear carried by a cast-steel arm firmly bolted to the crankcase.

Dimensional Details

The crankshaft is 2¼ in. in diameter and the material employed is chrome-vanadium steel, double heat treated. It is made in two pieces, the two halves being held together by a large bolt. The cylinders are block cast with ample water-jackets around the barrels, as well as around the valves. There are two inlet ports, as well as two exhaust ports, and the valves, which are 1¾ in. in diameter, are seated directly in the cylinder head. The valve guides are of cast iron, but the valves are of high tungsten steel. Two valve springs are used, one inside of the other. This eliminates the danger of the valve dropping in on the piston should a valve spring break.

One Rocker for Two Valves

A single camshaft is used, which operates the valves by means of short fork-shaped rockers, one rocker operating two valves. The camshaft is built up and stepped spacers are employed between the cams and bearings, which are ball-bearing. The camshaft is driven by means of spur gears

½-in. wide. These gears are also of chrome-vanadium steel, heat treated and run on ball bearings. The gears are inclosed in an oil-tight aluminum housing. A single gear drives the water pump, oil pump and magneto. The front cover plate is of steel as is also the flywheel. The connecting-rods are tubular, made from a solid forging of chrome-vanadium steel. A 1-in. diameter hole is bored through the entire length, making a very light, but at the same time very rigid rod. The bearing end has four bolts, and is bushed with bronze, Fahrig metal lined bearings. The upper end is bushed with a solid bronze bushing with a ⅞-in. hole for the piston pin. This pin is bored taper, the thicker part remaining in the center of the pin and gradually tapering towards the outside.

Pistons of Magnalium

The pistons are made of magnalium and weigh 12 oz. each. Only one groove is cut into the piston, and this is cut wide enough to hold four rings 1/16-in. wide. The piston pin is neither fastened to the rod nor to the piston, but is free to float, and is held in place by means of a wide steel clip, liberally perforated with holes. The head of the piston is supported by ribs radiating from the center and uniting with a lug which extends through a slot cut into the connecting-rod at the top of the piston pin. Two sets of spark plugs were provided for each cylinder, and a two-spark Bosch magneto was used. The weight of this motor is 600 lb.

Pressure Feed Lubrication

The oiling system is of the pressure type, our standard gear pump being used. The oil is carried in the sump and drawn from here through a strainer, after which it is forced through the oil leads to oil rings carried on the crankshaft. These oil rings carried the oil through holes drilled in the crankshaft to the connecting-rod bearings, the overflow from the bearings forming a spray which lubricates the pistons, wristpins and main ball bearings. Oil troughs are also provided under the rods and the rods are fitted with scoops so that a double system is employed for the lubrication of the big ends. The excess oil is drained back into the sump. A separate oil lead was taken from the pump to lubricate the overhead camshaft, a small stream of oil being directed onto each cam. The ball bearings carrying the camshaft are lubricated by splash from the cams. The excess oil from the camshaft housing returned to the oil sump through the gear housing at the front end of the motor, also through a return tube at the rear end.

Maximum Power at 2950 R.P.M.

The motors developed their maximum power at about 2950 r.p.m., or 3200 ft. piston speed per minute. At this speed the brake horsepower was 131. During the races the average speed of the motors was slightly less than above, or between 2600 and 2700 r.p.m., at which speed the horsepower was 124 to 128. On the test stand the motors were run up to 3500 r.p.m., at which speed the horsepower dropped slightly. The maximum pressure on connecting bearings, due to the pressure on pistons, was about 600 lb. per square inch.

The mean velocity of gas through inlet manifold was 2950 r.p.m., the speed of maximum power was 175 ft. per second, and through the valves 215 ft. per second.

The maximum mean effective pressure in the engine, figured back from the brake horsepower, was 132 lb. per square inch. This pressure was maintained from about 1400 r.p.m., to about 2200 r.p.m. At 2950 r.p.m. it was 118 lb. per square inch.

Discussion Obtains Timing of Engine

In opening the discussion on the paper on American racing engines, Chairman F. E. Place, vice-president of the Buda company, congratulated the section on having the opportunity to learn the construction and design of an engine which has made such wonderful records on speedways and in road races and has shown that America can produce engines and cars which can show their heels to the fleetest productions of Europe. He felt that the paper was particularly timely in that it was presented just before the beginning of a new racing season and in a center where racing interest is most acute.

Use 40-Lb. Valve Springs

George W. Smith, engineer of the Thos. B. Jeffery Co., inquired as to the weight of the valve springs employed and as to the method of holding the wristpin in place. In reply Mr. Milbrath stated that the valve springs were capable of 40 lb., and that the wristpins were fastened neither to the connecting-rod nor to the piston, simply floating within the piston and being held in place by a steel ring around the piston, which, however, acted in no sense as a piston ring. In illustrating this, Mr. John exhibited a connecting-rod, wristpin, and piston from one of the racing motors.

Features of Two-Cycle Racers

Mr. Marr, formerly engineer of the Amplex, mentioned some features of the two-cycle racing car with particular reference to the Amplex which competed in the first 500-mile race at Indianapolis. He stated that the engine was almost the stock motor, but was lightened as to its reciprocating parts as far as possible. The weight of the connecting-rod was cut down but the lightening of the piston was limited by the extreme pressure over the piston head. He said that the motor developed 86 hp. at 1650 r.p.m. for 4 hr., and showed its maximum torque at 1100 r.p.m., and its maximum crankshaft speed was 1800.

Temperature of the Oil

Robert J. Broege, engineer of the Buda company, asked as to the temperature of the oil in the Wisconsin racing engines, to which Mr. Milbrath replied that the temperature ran to 150 deg. on the test stand, but was not so high when running on the track on account of the cooling effect of the air, and that the running pressure decreased slightly with the speed and the power that the motor was developing.

Asked by E. A. Turner, vice-president of the Northwestern Expanded Metal Co., as to the valve timing of the racing engines, Mr. Milbrath stated that the timing was no different from that of the stock Wisconsin motor. He said that the timing was as follows:

Inlet opens 10 deg. after upper dead center.
Inlet closes 50 deg. after lower dead center.
Exhaust opens 50 deg. before lower dead center.
Exhaust closes 10 deg. after upper dead center.

Asked by F. C. Mock, research Engineer Stromberg Motor Devices Co., as to what cylinder volume the 75 ft. per minute velocity of gas was assumed, Mr. Millbrath answered that this assumption was at full cylinder volume. He stated that the oil temperature, he believed, was lower in the force-feed system employed in the engine described than it is in the splash systems on account of the cooling ribs, but no comparative tests have been made by him.

Fuel Economy Possibilities

Asked as to the economy of the engine, Mr. Milbrath stated that while no tests were run to determine the economy at moderate touring speeds, he believed that it would prove very efficient on account of the almost complete opening of the top of the cylinder by the valves, and also the hemispherical shape of the combustion space.

He stated that the compression space was figured at 20 per cent of the total cylinder volume, and when turned over by hand, a compression of 95 lb. per square inch was shown. The weight of the flywheel was 70 lb. The spark advance at maximum power was about 30 deg.

The History of the American Automobile Industry—25

Four-Cycle and Two-Cycle Engines on a Commercial Basis—Development of the Modern Motor Vehicle Fostered and Made Possible by Gasoline

By David Beecroft

WITH the epoch-making development of the Otto four-cycle engine of 1876, and the development of the Clerk two-cycle engine in 1878, the great principles of explosion engines were laid down, and both type of engines, the four-cycle and the two-cycle, were placed on a commercial basis. Since then the development has been that of improvements, but the basic principles as laid down by Otto and Clerk have been continued. This thus brings us to a dividing line in the history of the combustion engine. Up to this time it was the solution of the great problem of making the explosion engine a commercial success. It was a constant working in the dark. It was because of the efforts of many inventors that the final results were accomplished. Otto worked thirty-seven years, and others were working an equally long time. The solution was started by de Rochas in 1862 and was completed by Otto.

Gasoline of Prime Importance

Before carrying on the practical development of the automobile from the days of Otto and Clerk up to to-day it is necessary to digress here and introduce a few chapters on the development of the petroleum industry. Without the lighter fuel now known as gasoline, it is questionable if the motor vehicle would have developed as successfully as it has. Fortunately a copious supply of gasoline has kept pace with the development of the industry, and it is impossible to estimate the influence the fuel situation has had on the development of the motor.

It is an interesting coincidence that while the first oil well was drilled near Titusville, Ohio, by E. L. Drake in 1859, the principles of the four-cycle gas engine were laid down by de Rochas in 1862, just three years later. As previously stated, de Rochas had correctly conceived the necessity of four-cycles of operation in a gas engine as we know it to-day. It is particularly fortunate that practically at the same time the great gasoline industry should have been started.

Formerly a Waste

At the beginning of the automobile industry as a commercial business, this fuel was a waste because there was not sufficient use for it. Kerosenes of several different grades were on the market, and some of the lighter grades were practically what is known as gasoline to-day. They were regarded as extra hazardous, and were prohibited in some States lest they be used in kerosene lamps and cause damage. Gasoline was then used quite a little for private gas plants, and the early experimenters could hardly help obtaining a fluid that evaporated easily and burned cleanly. Its hydrogen content was proportionately quite high as compared with the carbon content, and the flame rather resembled an alcohol flame than a kerosene one. These facts explain how early American inventors succeeded by simply dropping the liquid on the inlet valve.

The History of Petroleum

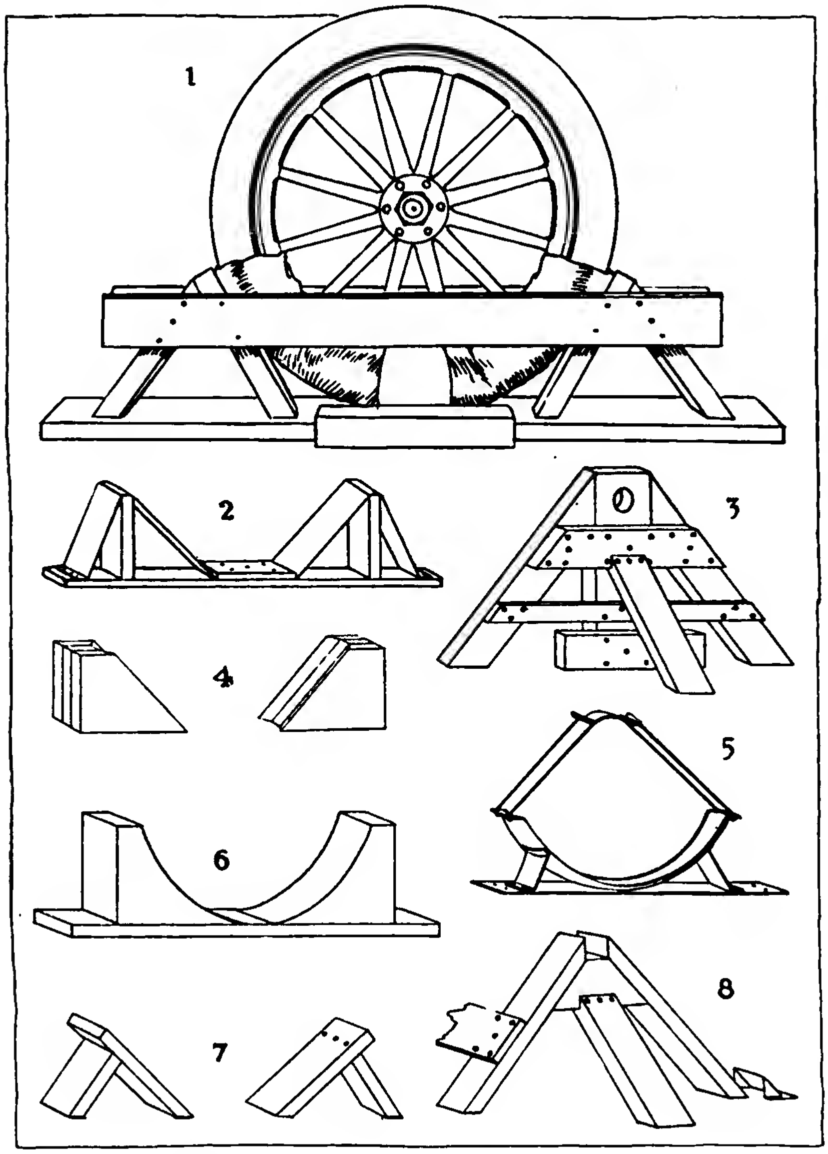
While the practical development of the gasoline industry dates from 1859, it will be appropriate here to show that petroleum in its varied forms has been in constant use for at least 3000 years and perhaps longer.

The production of petroleum runs back beyond the beginning of writing, and its story reads like a tale from Fairyland. Few things have had such a wide use during so long a time as has petroleum and its allied products. As a cosmetic for beautifying, a medicine for internal or external use to lessen pains and rheumatisms and embalming preservative, its use reaches from ancient Egypt to the present. Equally long is its use as a cement for bricks and stones or a slime for rendering crudely-built boats water-proof. The walls and buildings of Nineveh and Babylon, the tower of Babel and Solomon's temple, just as modern roads and building foundations, made use of petroleum products. Josephus tells us that the tower of Babel was constructed of burned brick and bitumen that it might not admit water. Herodotus says of the building of Babylon that large bricks were burned in furnaces and closely laid "using for lime or mortar hot asphaltas or bitumen." He also describes it as being obtained from the valley of a small river Is, a tributary of the Euphrates. That valley of pitch is still supplying its products to the surrounding country, and more recent writers describe it as containing many noisy springs and the pitch as used for "the staunching of boats."

Securing Shipping Security

Methods for Blocking Automobiles in Freight Cars Vary Widely—Evolution is Toward Simple and Cheap Types—V-Blocks Were Source of Many Damage Claims

THE question of blocking automobiles for freight shipment is a very important one for both shipper and railroad, for improper blocking may cause serious damage and pecuniary loss. For twenty years, manufacturers have been trying to solve the problem of proper loading, and in the early beginnings, there were many makeshifts, such as beams of wood spiked across the car floor, one touching the front wheels and the other supporting the back wheels of the automobile. Later, solid pieces of wood cut on an angle were used on both front and rear of each tire, being fixed to the floor with large spikes, and side strips made from boards 1 in. by 2 in. in thickness, and from 6 in. to 12 in. in width were nailed along each side. Boards were placed beneath these blocks as base boards, and the whole formed what was known as a cradle. There were many variations of this method, some of which still exist to-day, and all being rather crude and expensive. Some of these blocks were made from solid wood, and others were constructed from two pieces of wood, the latter being known as "V" blocks. Some manufacturers using solid blocks endeavored to have them curved so that they would conform to some extent with the curved face of the tire.



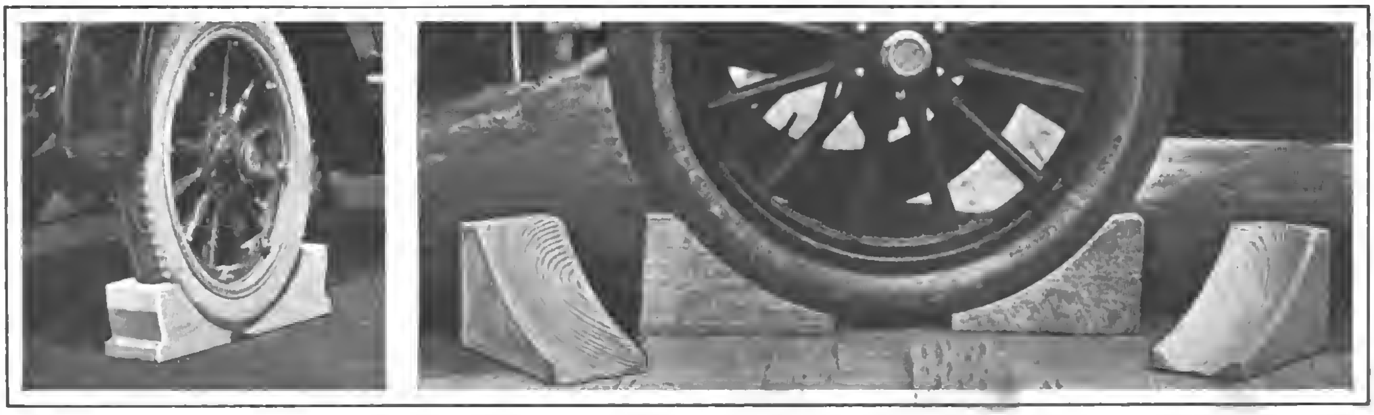
1. *Application of the two-piece V block.* 2. *Block of sheet steel stretched over wood blocks.* 3. *Hub horse used by Franklin.* 4. *Grooved block made from three pieces.* 5. *A costly metal blocking system.* 6. *Solid curved blocks mounted on board.* 7. *Two piece A block.* 8. *Studebaker axle horse used on front axle only*

It was believed by some of the railroads, and quite a number of shippers, that the obvious difficulties and objections to the "V" block and other straight faced blocks then in use could be overcome by using a metal block. The idea was that a metal block could be returned to the factory and used over and over again. Several were invented and tried out. The most popular principles employed were those of the stamped block, which was grooved to keep the tire from moving sideways, and to do away with the necessity for side strips. This metal block conformed in shape to the wooden blocks then in use. The stamped block, however, proved impractical. It was found that, in drawing the metal, it would crystallize, and the weight of the motor car with the constant jolting to which it was subjected, would crack the blocks and cause them to sag and fall.

The Hub Horse

About ten years ago, the H. H. Franklin Mfg. Co. developed a type of loading arrangement known as a hub horse. This horse was so constructed that the hub of the automobile could be rested in a hole made for the purpose, the four horses suspending the car from the floor. Studebaker, about two years ago, adopted a similar device. The effect of the horse, however, is to bring the entire weight on the axle. The automobile must be fastened so rigidly that there can be no play, and it becomes practically a part of the freight car. Thus, any blow received by the freight car becomes a direct blow to the machine. The wheels being suspended, the car does not receive the cushion of its tires.

Most of the blocking systems mentioned above cause chafed tires, and the claims from this source of damage alone aggregate thousands of dollars. The railroads from time to time have made an effort to overcome this trouble, and about 1911, the Santa Fé published a booklet entitled "Suggestions for Loading Automobiles," the main suggestion being that all tires be wrapped with a double thickness of burlap around the lower third of the circumference, and that the front wheels be tied down with two tie straps instead of one.



Left—Evans block curved to fit tire and with "heel" to receive nails. Right—Grimm block which is similar but without heels

This booklet concludes with the statement that the Santa Fé has adopted as a standard a straight faced grooved block which prevents the front wheel from turning on the steering knuckle, and therefore, eliminates tire chafing to a considerable extent.

V-Blocks Wrong in Principle

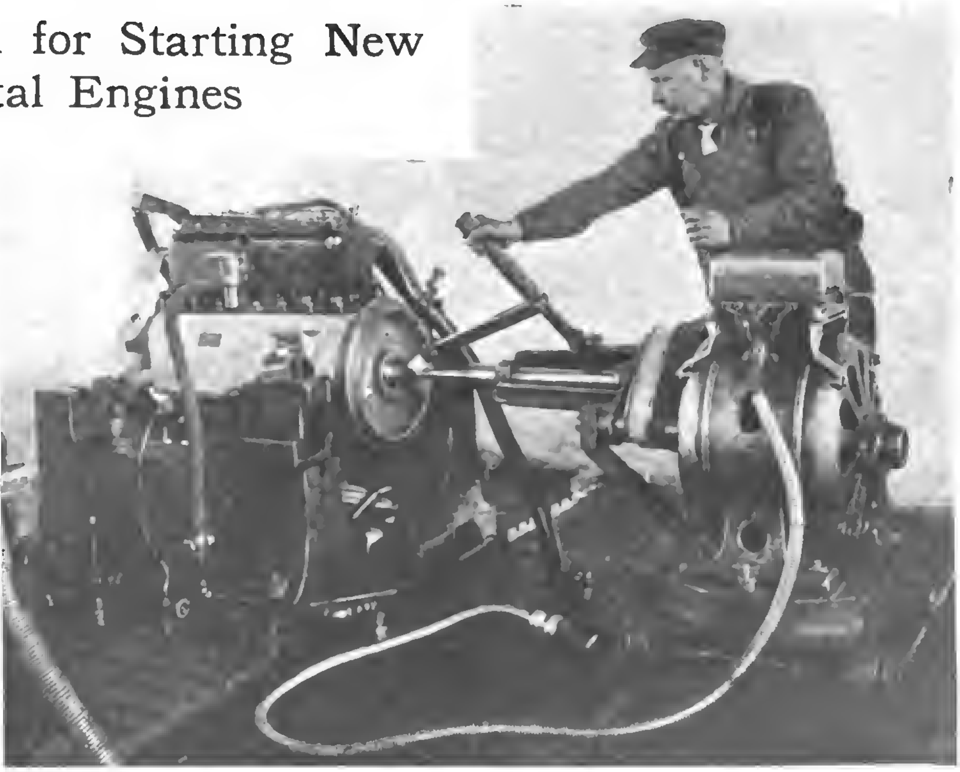
In the light of present achievement, this old Santa Fé block seems very crude indeed. The Santa Fé grooved block was so expensive that it never came into general use and, whereas there was a great variety of different methods used, the most popular up to 1913 was the V-block made from either two pieces or three pieces of lumber. These V-blocks were wrong in principle, crude, and were the source of constant claims for damage, but they were cheap, and a number of companies used them for this reason.

In 1913, Charles G. Grimm, an experienced wood worker of Palatka, Fla., conceived the idea of combining the curve and the groove in the same block. After months of experimenting, he applied for patents in the United States and Canada for the Grimm automobile shipping block, which was so constructed that it fitted exactly the contour of the tire, the wheel resting easily and evenly along the whole length of the groove. The groove of this block holds the wheel perfectly straight, and the shoulder or freeboard on the block prevents any chafing against the burlap blocks or sideboards. The smooth surface of the groove prevents any chafing of the tread, and makes it unnecessary to wrap the tires with burlap, or to face the blocks with burlap or carpet, as recommended by the Santa Fé for use with the old fashioned block. The Grimm block which is manufactured in Palatka, Fla., by the Florida Woodenware Co., from long leaf pine and cypress, was first used by the Cadillac company, and then it gradually superseded the other methods of loading, until in the latter part of 1915, thirty of the larger automobile manufacturers were using it exclusively.

In December, 1915, Edward S. Evans, associated with the Florida Woodenware Co., Detroit, applied for a patent on a similar block which is now being used extensively.

The chief difference between the Grimm and the Evans blocks is the "heel." The Grimm block is the more simple as the back of the block is a plain, perpendicular surface, but the Evans block uses a heel, which is incut in the back of the block, so giving a surface through which the nails can always be driven at a uniform angle and proper depth into the car floor.

Cranking System for Starting New Continental Engines



THE Continental Motor Co. has succeeded in effecting a considerable economy of time and labor by the installation of a powerful cranking motor for use in their large engine test shop. The electric motor is mounted on a carriage that runs on a track behind the rows of engines on the test blocks. At proper intervals there are floor plugs to supply the necessary current.

To permit the ready engagement of the starter, the shaft can be swung into any position till the clutch comes opposite the end of the crankshaft; the operators right hand controls this jaw clutch and the left hand the motor controller. It is stated that this starter can have 250 new engines running in less time than in starting twelve engines by hand.

The FORVM

PUBLIC MUST BE PERSUADED TO ACCEPT KEROSENE AS A FUEL BEFORE IT CAN BE ADOPTED—AIR COOLED AND TWO-CYCLE MOTOR ADVANTAGES

Advantages and Disadvantages of Kerosene as a Fuel

By B. H. Pomeroy, M. E.

I HAVE been following the various writings upon the question of kerosene for a fuel for combustion motors and am more than amused at the way some go about telling how to get the required results.

It is not the booming of kerosene in a combustion motor that is important, but getting the public to accept and use it as a fuel, as it has its advantages and again its disadvantages.

Arguments Pro and Con

Advantages are: high explosive force, freedom from carbon on plugs and cylinders and greater mileage, gallon for gallon and less oil required for lubricating of cylinders.

Disadvantages are: for persons who fill tanks on cars and slop it on the cushions and floor mats, leaving a stain that soils the clothes; but this could be overcome if the general public would adopt kerosene as a fuel. The mere fact of converting it into a perfect explosive gas is no great task, as the writer is a firm advocate of kerosene as a fuel and has been using it for four years as such with perfect success and finds no trouble whatever, and when you say kerosene burners to people, they simply say, "Gasoline is good enough for me," and this is one reason why the kerosene motor is no further ahead. There have been several firms which have branched out on kerosene and advertised to some extent, but they seem to have abandoned the proposition. But why have they abandoned it? Simply because the public has not taken kindly to it.

The carbureter of to-day is not adapted for kerosene, but a very simple device can be made. The one which I have on my own car to-day—and have used for the past four years—has given entire satisfaction with no more bad odor or smoke than the present grade of gasoline gives. I am using a model L Schebler 1¼-in. carbureter with my attachment, using the regular throttle, but with changes in the air valve and venturi. I can idle from 60 to 1200 r.p.m. without the least sign of loading up and can see no waste or overflow from carbureter when I stop the motor after running for an hour on forced suction or closed throttle.

Kerosene a Logical Fuel

My motor is easily started, almost always on a quarter turn of the crank, but cold weather makes some difference, not enough to speak of. I use my car 365 days per year and I am at a loss to understand why others do not adopt kerosene as a fuel. The kerosene proposition is probably like a great many good inventions—held up on account of insufficient confidence of men with capital to help out the inventor. In my case, I have worked with kerosene and experimented with it since 1900, when I made the first worm-drive rear axle and had it on exhibition in New York. Then I was discouraged by the majority of automobile men, who said the device was out of the question because of friction; but to-day, what about it? The same thing applies to my kerosene-burning motor. There are several good kerosene motors not of the hot bulb type. Secore, for one, gives perfect combustion, and why not others? Simply because the inventors are afraid to come to the front with them, on account of having their inventions swept from them.

When the automobilist gets to using kerosene for fuel as a regular thing then we will see the price go up, the same as gasoline. As long as oil is controlled by a few firms this will invariably be the case.

I am not finding fault with any particular firm, but think and know that this proud and ingenious nation of ours should find a way to corral this everlasting increase in price of fuel. I do not cherish the idea that I as one should be classed as a traitor for keeping my invention as others of my class are doing, but when the time is ripe and the general public is willing to accept, I am ready to unfold my invention. Of course I desire to benefit my brother man as much as I can, but when one has spent several years at perfecting a thing of this kind, he desires to see something done with it, and not have it shelved and the public go on in the same old way.

Air Cooling and Two Cycles for Higher Efficiency

By Chas. E. Duryea

THE several articles and editorials on conservation and increased efficiency in your recent issues are most interesting. The public badly needs more of this education. Mr. Sargent's plea for a higher compression with low throttle instead of lower compression is certainly along the right lines. His suggestion to vary the closing of the inlets and thus secure a cutoff action is good, but it is not clear how we can prevent the driver from using the most powerful mixture and the latest cutoff possible in order to get maximum power and thus get compressions too high for the mixture, resulting in pre-ignition with its pounding and disadvantages. The automobile does not go into the hands of trained engineers, but is driven by everybody and must be so simple and foolproof that it cannot well give trouble, or be tampered with in any way.

Two-Cycle Fuel Economy

One of the reasons why I look forward to a perfected two-cycle is the fact that it employs constant compression and so may make better and more efficient use of its fuel when throttled than can the usual four-cycle. Mr. Sargent's figures showing the disposal of the fuel energy are very interesting but hardly correct for the average automobile engine. The energy expended in work is probably under 20 per cent, as shown in next column, the engine friction is probably nearer 10 than 5 per cent. The radiation and exhaust are probably somewhat higher than 25 per cent and the jacket loss probably lower than 45 per cent.

Why Not Compound?

The best way to increase the work energy would seem to be by compounding. Nowadays buyers seem to like more cylinders and by using one-third of them as second expansion affairs we could save the need for mufflers and add 20 per cent or more to the work figures. Steam engine practice indicates that it is more economical to use low-pressure cylinders rather than attempt to expand to the limit in the high-pressure cylinder. Compounds heretofore made have been water-cooled, whereas if they had been air-cooled the efficiency would have been much higher because the heat would have been more largely retained for work instead of foolishly used to boil water.

The big loss being out through the jacket and radiator it would seem apparent that air cooling needs adoption. It is perfectly easy and safe to run an air cooler with its walls at 360 to 500 per cent, which is two to three times the usual waterjacket temperature. This means that very much less heat escapes to the cooling system and accounts for the superior showing made in efficiency contests by the air-cooled cars. The first look for the man looking for low fuel costs should be toward the cars which use their fuel for propulsion rather than for water boiling. Two and three times the mileage per gallon is equivalent to cutting the fuel price in two and three with the added advantage that some fuel is left for the other fellow.

Car Weight Important

Car weight is another consideration in the line of conservation. Comfortable riding is a matter of design and springing and not of weight. While it is true that with a given unsprung weight the heavy body rides more easily than the light one, it is also true that the light body does not need the heavy wheels and axles to carry it and so is not affected by the same unsprung weight. Buggies and cycles went through this improvement from heavy to light with great gain. The automobile will do so just as soon as buyers refuse to take heavy cars. Motorcycles and buggies weigh very little more than their maximum loads. When will we get automobiles approximating this ratio? A 4000-lb. car is three times as heavy as needed to carry seven people and costs twice as much to run, not to mention added tire and other expenses.

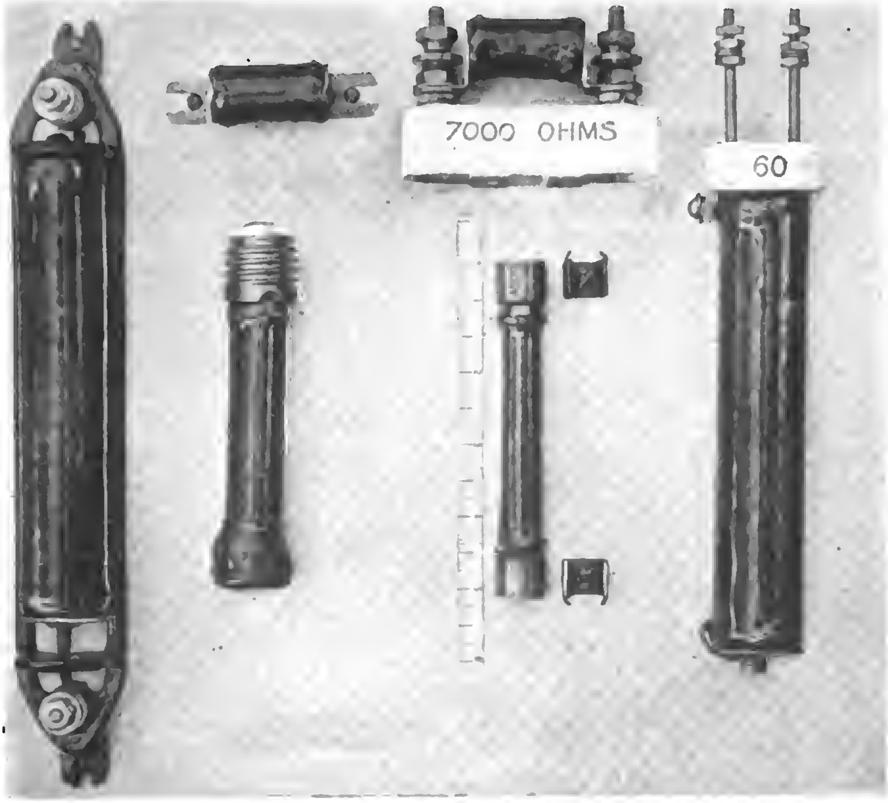
Compact Ward Leonard Resistance Unit

Adaptable to a Wide Variety of Circuits and Can Be Furnished Up to 10,000 Ohms on One Layer of Wire for Standard Conditions

A COMPACT unit of high resistance and of moderate current carrying capacity has been brought out by the Ward Leonard Electric Co., Bronxville, N. Y. The resistance material, which is illustrated herewith, is made up of units of wire of practically zero temperature co-efficient, wound on porcelain tubes and covered with a vitreous enamel. The resistance wire is embedded in a substance which expands and contracts at the same rate as the wire does itself within the limits of ordinary electrical usage.

This harmonious expansion and contraction prevents adjacent turns of wire from closing together and short-circuiting, which would in turn cause a change in the resistance of the unit and might cause burn-outs in the circuit.

The vitreous enamel in which the wires are embedded and by which they are entirely covered, protects them from the atmosphere. As the entire wire is hermetically sealed in this way it cannot deteriorate owing to the action of the atmospheric moisture or other corrosive elements. The coating of enamel over the wire is thin and is a good conductor of heat, thus keeping the temperature low by dissipating the heat.



Compact Ward Leonard resistance units which are rust-, water-, fire- and dust-proof

By the practically zero co-efficient of the resistance wire is meant that its resistance does not alter with changes of temperature and this is an important factor in practical installations of all sorts.

Units Are Strong

Mechanically the resistance units are strong, being compact, non-abrasive, rust-proof, water-proof, fire-proof and dust-proof. The terminals are sturdy and the connection between the resistance wire and the terminal leads is embedded in the vitreous enamel which preserves the joint against depreciation. The shapes of the units are shown in the illustrations. These illustrate units arranged to be screwed into lamp sockets, fitted with ferrules for fuse clips equipped with angle ends, or for wall mounting. Any of the units shown can be furnished with resistances as high as 10,000 ohms on one layer of wire.

Automobiles and Trucks Big Assets To German Army

Enable Rapid Transference of Reinforcements Between Various Battle Fronts—Constructional Points Brought Out By War Service—Coping with Tire and Fuel Situations

By E. A. Langdon

ACCORDING to enthusiastic Germans, three factors have been responsible for the successes of the Kaiser's armies in Poland: Von Hindenburg, the big guns and the automobile. It would be difficult to choose any one of these as the supreme factor, for without the wonderful mechanical equipment, even Germans admit, the field marshal could not have achieved what he did. This applies not only to the later campaign and the struggle for Warsaw, but even more to the early stages of the eastern fighting, when East Prussia and West Prussia were considered to be seriously endangered by the millions of Russian soldiers.

It is claimed that the plans for the battle of Tannenberg, for instance, were largely of a makeshift nature, in that the Russians moved into Germany along somewhat different lines than was expected of them, and that millions of German troops had to be rapidly transferred from more southerly points of the frontier to the north. This could never have been done without thousands of automobiles, in spite of the fact that several lines of railroads, very efficient in a military sense, run parallel with the line of forts Koenigsberg-Thorn-Marienburg. Likewise, it was due to the automobiles that every kind and quantity of artillery required could be brought to the battlefield in time to defeat the Russians. Of course, the automobile operations were by no means restricted to the preliminary work of the battle, but as positions shifted, the motor equipment was always kept working hard.

The First Big Demonstration

This was the first demonstration on a large scale of the tremendous military value of the automobile to Germany. The work, consisting of wholesale movements of troops and cannon and ammunition, was repeated with relatively small modifications in the several battles of the campaign of the fall of 1914. At the same time, cars enabled the Austro-Hungarian troops to make the best of their strategic retreat through Galicia, in the face of Russian armies which were in vast numerical superiority. It was the unfailing supply of enormous quantities of munitions which made it possible to hold the Carpathian passes against the Russians thrown into them regardless of losses. Finally, automobiles constituted, to a large degree, the driving force which turned the Russians from the Carpathians and Galicia into Poland, ending the first and opening the second great stage of the eastern campaign.

An Automobile Railroad System

The second stage consisted largely of the advance, sometimes rapid and sometimes slow, of the united Teutons toward Warsaw, and after the conquest of that city, to the Brest-Litowsk line. Most of this advance was made in a country of soft soil, very poor in the way of roads, while most of the railroads were destroyed by the retreating Russians wherever they had time to do it. Fortunately for the invaders, the solid railroad beds could not be destroyed in the short time given to the retreating enemy, and this made possible the creation of an "automobile railroad system," in which the cars followed the lines of the railroads. The latter radiate from Warsaw toward the Russo-German frontier, being also constructed, largely, from a military point of view. Hence, concentration along these radius lines toward Warsaw was relatively easy and automobiles were able to do their best. Of course, a very great amount of their work was done over roadless ground, and here, too, the value of the cars was tested and proved. But, in a general way, the hardest work for automobiles in the east was done during the Carpathian campaign, when the machines had to plug through snow and mud several feet deep and often had to be raised and got under way.

Unique Car Uses

It stands to reason that cars served all kinds of work for which they had never been intended. The writer remembers, as specially striking, the instance of a car jacked up with its rear axle geared to the generator of a wireless telegraphy outfit, and another case, where the motor actuated the dynamo of a huge searchlight. One of the most interesting emergency uses to which a car was put was when the motor of one of the large siege guns bombarding one of the Russian fortresses became inoperative. In a very short time the crankshaft of a nearby automobile had been geared up to the shaft driving by the electric motor of the gun and controlling the position of the latter, so that the gun could continue to operate until a thorough repair could be made.

On the western front, automobiles also found plenty of work. This applies especially to the fighting in the Champagne and Vosges, where the net of railroads is more sparse than in Northern France and Flanders, and where at times most violent fighting went on. Several hills commanding the surrounding ground, such as the well-known Hartmannsweilerkopf, changed hands as often as a score of times during the war, and the party on the offensive of course had to bring up troops and fighting machines under better cover than that of the strategic emergency railroads serving a position which is securely held. In more than one case, all the fighting against the forces on such a hill was in vain, until the supply of heavy ammunition was cut off from them, when the position was carried by storm. In some of these storms, armored cars with small-calibre guns participated, and in spite of the obvious difficulties of such a hill climb made surprisingly good showings.

One might even say that Germany succeeded where motor cars could operate and did not succeed where they failed. Wherever there was a possibility of quickly attaining a position required and suitable for effective attack, this possibility was realized through the work of the automobile. It was *the alliance with the automobile* which made the 30.5 and 42 cm. guns as effective as they proved in scores of siege operations, including Liege, Antwerp, Maubeuge, etc.

Field Repair Depots

Mention has already been made of Factories Behind the Front, as the repair shops are called. In the east these shops, of which there are a number, are from 150 to 200 kilometers behind the front, while in the west they are much closer to it and in better communication therewith. The chief reason for this different situation is that the positions in France and Belgium are considered by the invaders to be absolutely impregnable; to support this argument they point to several gigantic attacks which left the German front almost unchanged and which were stayed by an army of much smaller number than those attacking the lines of the Teutons. Needless to say that automobiles played their part in these very efficient defense acts, transferring reserves and materials from one point to the other, according to local requirements.

Steering Gears Weak

As to the technical information which the war work of the motor car brought to the light, one of the most striking facts discovered was the general weakness, relatively speaking, of the steering gear. The steering equipment seemed most apt to give way under the terrible stress of operation. From 10 to 20 per cent of the repairs necessitated by work, not military or fighting damage, had to be made on steering equipment. The simple explanation of this fact is that under the strenuous conditions of military service crystallization of this hard-working part sets in much more rapidly than in ordinary work, where a car may be kept on fairly decent roadways most of the time.

Radiators Protected

One trouble much complained of is the lack of protection of the radiator. The slightest injury of the honeycomb developed very quickly into serious trouble since motors are always working at top capacity. Whenever possible, radiators are being protected by cheap but strong devices, such as wide-mesh, heavy-wire hoods. It is said that German trucks, constructed with a view to getting government subsidies for their purchasers, were better protected from the start than American trucks, which latter proved excellent in a great many respects. The Germans frequently praise the relatively low weight of American machines which permits greater fuel economy, a most important factor in Germany to-day. In this respect, American cars average much better than European makes.

Clearance a Factor

Another point which had not been foreseen sufficiently was ground clearance. Automobiles had of course to make their way over the most unimaginable ground and many a car was delayed for hours or, worse yet, disabled for weeks. Here, too, light and cheap American products gained laurels.

With the natural irregularity of supplies that accompanies war operations no matter how well managed, maximum carrying capacity for fuel and oil of paramount importance. The tanks, however, proved almost invariably to be hardly sufficient. Hence, whenever automobiles go to repair shops, small tanks are replaced by large ones, which latter are generally of aluminum, iron and copper being too costly for this kind of equipment at the present time.

Aluminum in Demand

Apropos of the increasing use of aluminum, there is a very noticeable tendency toward a reduction of dead weight in German automobile construction. Alloys of the nature of magnalium, a combination of aluminum and magnesium, which is both light and strong, are becoming very common, and German engineers and metallurgists do not tire of emphasizing the great help which the war rendered to their work by forcing the rapid development of many questions of this kind. There exist a great many new articles which enter into the manufacture of automobile parts, and several developments of paramount importance are said to be in the status nascendi. One of these, it is rumored, is an alloy composed mainly of aluminum to which has been added a metalloid element, and the mixture is said to closely resemble steel in its elastic possibilities.

Another novelty, or rather a series of innovations, exists in the fuel line. Let no one be surprised if after the war Germany will use almost no gasoline for her automobile motors. Not only has the use of benzol increased tremendously, but alcohol has become at least as common for motor service, and the very design of automobile motors has been adapted to the character of these novel fuels.

Synthetic Rubber Used

It has been mentioned in a former article that synthetic rubber is now a practical article in Germany. Seeing that Germany's imports in this very valuable and important substance, namely, para rubber, became practically nil with the outbreak of the war, the plans for making the material in a synthetic way were rapidly put on a commercial basis, and almost all new tires are now made of this material. Germans have no doubt that after the war they will soon increase their output of synthetic rubber and that they will be able to do so at such a low price as to introduce in a short time huge quantities of the material in the world. German technologists in particular are very optimistic regarding this development and more than one has been heard by the writer to predict for the rubber industry the same fate as that befell the indigo industry decades ago, when synthetic indigo was first brought out by the Germans and in a short time destroyed completely the trade in the natural East Indian product.

The Patent Situation

This incident, of which there are a considerable number of parallels, points to an important evolution in German industry. Until a short time ago, the Empire recognized what was known as secret patents, claims and specifications to inventions, which were filed by the government, but not published, yet protected the inventors' rights. Only the growing power of liberal business interests disposed in time of this rather undemocratic institution; but Germans now believe that the war will be followed by commercial competition so keen as to almost amount to a trade war against Great Britain and possibly America, and they will do their utmost to protect national business interests, even at the expense of some free institutions. It is to be supposed that, if these plans realize, the Germans will offer to the world after the war numerous new chemical products the compositions of which will of course be determinable by analyses, while the process of manufacture will be kept utterly secret. The Germans argue that such a course will be more beneficial to them than to patent their inventions abroad and run the risk of losing their title thereto, either temporarily or permanently, through war or other extraordinary event, as was the case with German patents in England. The advantage of secret, over the open patent method, German engineers claim, is well demonstrated by the thermit welding system, which requires aluminum in powder form for doing the welding work; but the method of producing the powder is not patented, yet kept strictly secret. Such a system of business, involving secrets of manufacture and trade, can, according to the Germans, be successful in Germany, though perhaps not everywhere else; since, as the Germans never tire to state, the German businessman, engineer and workman are ruled by a Berufsethik (ethics of vocation) which forms as essential and important a part of their morals as the decalogue.

Germany Adopts Production

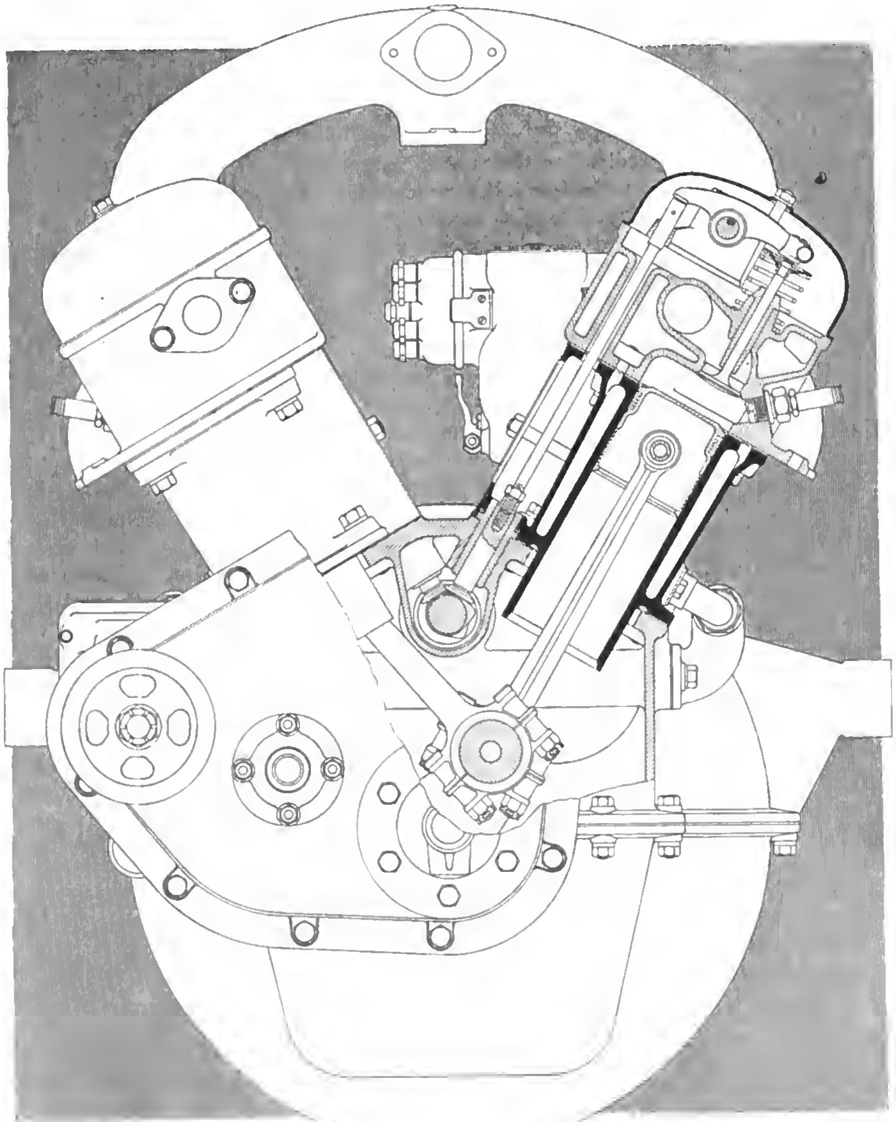
It may not be amiss to state that plans are under way for the organization of one or perhaps even several enormous motor manufacturing corporations which are to produce cars upon the myriad basis as it exists in the American industry. Germans thereby not only expect to curb the imports of American-made cars, which steadily increased during the six or eight years before the war, but they intend, in course of time, to become the chief power of supply for the international automobile market. For this, Germans state, they are indebted to the lesson Americans gave them during this war by exporting countless automobiles to Europe. Germany seems to believe that sooner or later there will be a chance for her also to determine history by commercial methods.

One more fact should not be forgotten in this connection. About one year ago, it looked as if the coming of peace would bring in time a wonderful chance for American industry exporting its products to Germany and the countries of her allies. For months, however, negotiations have been under way between these powers to complete, with the re-establishment of peace, a customs union, enabling them to buy industrial products from German and Austrian industry and to obtain agricultural products cheaply from the Balkans. Germans are inclined to believe that such a combination could soon be extended to include Italy and Scandinavia; and if these plans materialize only to the extent of one-half their scope, this will mean a huge obstacle in the way of any American industry figuring upon exporting to Central Europe after the war.

With peace expected in England by the end of next year, and in Germany considerably before that time, it is very important that Americans be prepared for the opportunities which the end of the war will bring. If rightly handled, these should be fully as profitable, if not more so, than the war has proved to industry of the Western Hemisphere.

Weidely Engine on Two Chassis

INTRODUCED toward the end of last summer, the Weidely twelve-cylinder engine has since been fitted to many Pathfinder cars and to a fair number of the new H. A. L. which made its maiden appearance at the New York show. The Weidely engine is comparatively small for a twelve, being 2⅞ by 5 in., giving a piston displacement of 389.5 cu. in. The overhead valves are operated by push rods from a single shaft with twenty-four cams, the tappets being of mushroom type. Adjustment is given by a screw in the end of each rocker, secured by a pinch screw, and this design makes the adjustment very accessible.



Section through Weidely twelve-cylinder 2⅞ by 5-in. engine

The crankshaft is 1⅞ in. in diameter and has three bearings, while it is drilled throughout for oil supply to the lower end connecting-rod bearings. The latter are placed adjacent on each crankpin and are stiff drop forgings.

Cast-Iron Pistons

For the pistons cast iron is used, with three narrow rings, and to reduce the spread of the cylinders the foot is carried down into the crankcase for a distance equal to three-quarters the length of the piston. There are four cylinder blocks, but the detachable heads are not thus sub-divided. In the sectional cut it can be seen that the intake manifold is duplex, carrying the water also. The water pump is located on the right side of the crankcase midway of the length, being driven in tandem with the generator. For the left blocks of cylinders a water pipe is taken across the engine passing through the crankcase at the center.

Camshaft Separately Oiled

For oiling the lubricant is fed from the gear pump to the three main bearings and is caught in centrifugal gutter rings on the crank webs as it escapes. From these gutters it is led into the crankpins and then taken up pipes to the wristpins. The camshaft is contained in a separate tunnel which gets a separate supply of oil, the overflow going to the front end of the engine where it lubricates the timing gears. There are two screens, one a sheet of fine mesh covering the whole of the bottom part of the crankcase, and the second still finer, being a smaller affair on the suction side of the pump.

The Rostrum

70,000 Miles at 3½ Cents per Mile

EDITOR THE AUTOMOBILE:—Perhaps the following figures will interest your readers. They give actual costs of operating an automobile for some 70,000 miles covering a period of three years, one man doing this driving and two cars worn to a point where it seemed best to sell them and buy new rather than spend more money for repairs.

In January, 1913, we bought a Ford runabout for one of our traveling representatives. In twenty months, or until September, 1914, he drove this car 37,550 miles at a total cost of operation of $1,256.72 or $0.0334 per mile. At that time we sold the car, purchasing a new Ford runabout. Adding the depreciation to the old car, the total expense was $1,566.72, making the total actual cost per mile $0.0417.

The new car was run 31,619 miles up to the present. We have just purchased a third runabout.

The total cost of operating the second car for eighteen months was, $817.43 or $0.02574 per mile. Including the depreciation the cost was $1,046.43 or an actual total cost per mile of $0.03309.

On the second car the itemized operating costs per mile were as follows:

Gasoline	$0.0082
Oil	0.00205
Tires	0.00784
Repairs	0.00495
Storage	0.0027
Total	$0.02574

You will note the cost of operating the second car was considerably less than that of the first car. We think this can be charged altogether to the skill of the driver who had never operated an automobile up to the time he began driving the first car purchased. Being entirely unfamiliar with the care of an automobile, he did not know how to handle it to get the best out of it. For instance, once he allowed the oil to get sufficiently low and a bearing was burned. After operating this make of car for some 70,000 miles, he has become something of an expert and gets the very most from his car all around in tires and repairs, oil, gasoline, etc. His gasoline mileage aside from the winter season averages 23 to 25 miles per gallon.

In conclusion we might say that he covers all kinds of roads in the three States of Connecticut, Rhode Island and Massachusetts.

Middletown, Conn. G. E. M.

Insufficient Gasoline at High Speeds

Editor THE AUTOMOBILE:—I have an Abbott-Detroit four-cylinder 4½ by 5½ Continental motor which has caused me a lot of annoyance. Every once in a while the motor will backfire at the most critical time, especially when climbing hills and sometimes on level ground when running at a moderate speed. There is a Stromberg carbureter and through the glass float chamber I am positive the gas is there. I cleaned out the whole of the gasoline system. Tried about forty different adjustments on the carbureter without results. Am positive valves do not stick and cylinders are free from carbon. Magneto is a Splitdorf model T and is a rebuilt one from the factory in exchange for the old one. Do not think the trouble is there as the car will run very well most of the time. Found leakage from high-tension wires in metal tube. Took those out and replaced clear of all metal and put in all new spark plugs. Thought I had it but the trouble still shows up. What is it?

2—Please illustrate by diagram distance armature breaks from field of Bosch and Splitdorf magneto to get the peak load. I understand the breaker points separate at this point throwing out the maximum amount of current to coil.

3—I am interested in running on kerosene, and two or three years ago I tried experiments on a Ford with such good results that you could not tell the difference in power. I used gasoline to start and the regular carbureter. I used to coil my feed pipe around the exhaust at its hottest place, thence to the carbureter, as the secret is to get the kerosene well heated before it enters the carbureter. On account of the heat a cork float is not good in the carbureter as it blisters the shellac. This is not practical on short runs as it needs too much manipulation; but on trucks or buses when the engine is not stopped all day it effects quite a saving. I also had a clean engine and as much power as I ever had.

Watertown, N. Y. A. F. W.

—Although you state you have cleaned out the whole gasoline system it seems quite evident that there is a clogging somewhere in the line or else the carbureter is too small. It is evident that you are not getting enough gasoline at high speeds. There is also a possibility that the carbureter air valve sticks open at higher speeds.

2—Your question is not quite clear but it is supposed that you mean to ask the point at which the primary circuit is broken in relation to the position of the armature with regard to the fields. On all magnetos it is the aim to break the primary circuit at the peak of the current wave and this is when the armature winding is cutting the greatest number of lines of force in the magnetic field. Exactly what this position is will depend on the arrangement of the magnets.

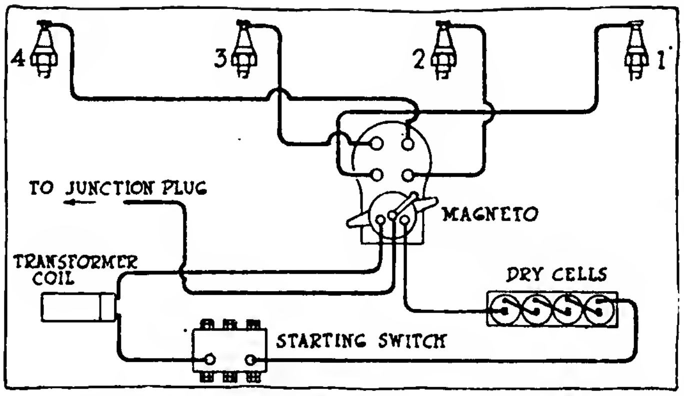
3—It seems to be quite practical to run on kerosene even with the ordinary type of carbureter as long as sufficient heat is added to assist the vaporization. The trouble of course is largely in being able to start the motor on this fuel.

Wants Information on Coey Flyer

Editor THE AUTOMOBILE:—Kindly publish information on adjusting the steering gear of the Coey Flyer 1916 model, so as to take up the backlash or play in the steering wheel. I have tightened up the nut on top of gear housing without avail, the wheel still has about 6 in. play.

The clutch thrust bearing on this car has given considerable trouble. The balls are ¼ in., nine in number and are contained in an ordinary ball retainer, such as is used in bicycles. This retainer has broken several times, allowing the balls to break and lose out. I have had to replace balls and retainer three times, during which time car was only driven 1600 miles.

2—What makes the motor keep on firing after being switched off? It appears to me to be the mixture. The carbureter is the Stromberg with only one adjustment, a small



Wiring diagram of the Maxwell car showing connections and circuits

knurled nut, on top of the float chamber. The motor seems to run best when this nut is opened about five or six turns to the left, but it consumes too much fuel. I can only get about ten or twelve miles per gallon of gasoline. Give a suggestion on adjusting this carbureter and state how many miles per gallon I should get out of this car, with the proper adjustment.

East Palestine, Ohio. E. M. G.

—The ring gear you refer to has two adjustments: On the top of the worm and on the side for the sector gear. In all probability you have taken up the end thrust on the worm but did not disturb the adjustment of the sector. It is also advised that you examine the steering arm as any steering arm has a tendency to work loose, owing to the great strains to which they are subjected. A little lost motion at any point in the steering gear means considerable at the wheel.

The clutch thrust bearing to which you are referring is being replaced gratis by the Coey company as the first few cars which were sent out had thrust rings which were not up to specifications. Since you have replaced these frequently there is a possibility that you have neglected to place light grease in and around the bearing, which is the only method of lubricating this thrust bearing.

2—Presumably this will be owing to carbon in the motor. It cannot be due to the carbureter if the ignition is switched off. Have the cylinder removed and all carbon thoroughly scraped off. You will probably find that cleaning the motor will enable you to operate the carbureter on an adjustment which will give a leaner mixture and therefore cure the present heavy consumption.

Float Valve Seat Is Damaged

Editor THE AUTOMOBILE:—Will you please tell me how to grind in the float valve of a Schebler carbureter that leaks slowly; a new needle has not cured the trouble. The needle has a steel cone on a brass stem.

Scranton, Pa. D. R. C.

—It is evident that the float seat valve has become damaged and this should be repaired with a float valve reseating tool. If the carbureter is sent to the manufacturer or to the nearest distributor, which in your case is the Manufacturers' Supplies Co. of Philadelphia, they will be glad to reseat the float valve seat in the bowl so that the valve will seat properly and eliminate flooding trouble.

This would have to be done with a special tool in order to get a satisfactory job, so it is better to either send the carbureter to the manufacturers in Indianapolis or to the agency in Philadelphia.

Ignition System of Maxwell 25

Editor THE AUTOMOBILE:—Please explain ignition system on 1916 Maxwell 25.

Uniontown, Pa. H. G.

—Ignition on the Maxwell car is furnished by a Simms high-tension magneto assisted by dry cells and transformer coil to facilitate starting. The ignition system is of the dual type, having a small non-vibrating coil which is attached to the frame of car. This coil is unaffected by either moisture or heat, and being non-vibrating there is nothing to get out of order or require any adjustment.

Four dry cells are used in connection with this system, and care must be taken to connect them correctly. This is most important, and the wiring diagram should be consulted before disconnecting or connecting any of the ignition wires.

The switch operating the battery circuit is in connection with the starting switch and when the starting pedal is depressed, thereby throwing the starting motor into operation, the current flows through the switch, coil and magneto. As soon as the engine starts or the starting pedal is released, the circuit is automatically disconnected and the engine runs on the magneto. It is readily apparent that the operation is extremely simple with the additional advantage that it is impossible to unconsciously leave the switch on and thus run down the batteries.

To start, the spark should be fully retarded—not only to eliminate the possibility of back-firing but because the spark is actually hotter when the spark control lever is fully retarded, with the engine running at very slow speed. At medium, or high speed the best results are secured with the ignition partly or fully advanced.

Data on 1912 Overland

Editor THE AUTOMOBILE:—Will you state, if possible, the amount of money earned as prizes by each of the following drivers during the 1915 racing season? Cooper; Anderson; Resta; O'Donnell; Rickenbacher; Alley; De Palma and Burman.

2—If possible will you print the horsepower curve of the 1912 Overland model 60?

3—What is the maximum number of revolutions of this motor per minute?

4—With this model stripped down, in good working order, geared 2½ to 1, what speed should it attain?

Somerville, Mass. C. R. N.

—The amount of money earned by the drivers you mention is as follows:

Resta	$37,750	Rickenbacher	24,000
Anderson	37,000	O'Donnell	19,000
Cooper	30,750	Alley	12,200
DePalma	24,600	Burman	11,000

2—THE AUTOMOBILE has no horsepower curve of the Overland 1912 model 60.

3—Maximum speed is from 1800 to 2000 r.p.m.

4—If this model were stripped down and in good working order geared 2½ to 1 you should be able to obtain a speed of from 60 to 65 m.p.h.

Recommends Use of Tire Caliper

Editor THE AUTOMOBILE:—In looking over THE AUTOMOBILE for March 9, I was much interested to read the article in The Rostrum by M. C. C. on prolonging the life of automobile tires. M. C. C.'s idea of changing the tires around on the different wheels seems to have worked out very well in his case, but he evidently is willing to go to more trouble than the most of us. In his letter, M. C. C. says, "While on this subject, why not give us a well worked-out table showing the actual inflation pressures for tires of different sizes and under different loads, giving actual road weights and not empty car weights which plainly mean nothing when taking a seven-passenger car and a runabout with the same size tires. There is no use carrying a greater inflation than is necessary and proper for the weight the tire has to support."

The writer has felt a good deal the same way about this, and a few months ago the problem was solved by the use of a tire caliper designed to take actual load into consideration in maintaining air pressures. For instance, the tire caliper is placed over the tire at the top where there is no load strain. After this is done, the reading is taken on one of two scales shown on the caliper. The caliper is then set at the same reading on the second scale, or load scale, and the caliper placed over that part of the tire which comes into contact with the ground. If the tire does not fill out the space within the jaws of the caliper, there is too much air in the tire for the load. On the other hand, if the caliper will not slip over the tire, there is not enough air in the tire, and more should be put in.

To the writer, this seems to be the simplest and most satisfactory method that he has used, it being much less trouble than the air gage, which necessitates removing dust and valve caps. I believe that M. C. C. will be interested in this, as well as many other motorists who are anxious to cut down tire bills.

Boston, Mass. G. A. S.

Wire Cloth Strainer vs. Chamois

Editor THE AUTOMOBILE:—In two different issues of THE AUTOMOBILE I saw articles concerning a charge of static electricity being generated by passing gasoline through a chamois. In order to set myself right on the matter I wrote to the Department of the Interior, Bureau of Mines, Washington, D. C., for authentic information and for the benefit of your readers I am quoting from a letter received from this department.

"There are various reports which have come to the attention of this bureau which would make it appear that when gasoline is poured through a chamois skin in a metal funnel, the funnel is charged with static electricity. If the funnel is grounded, naturally the charge passes off to the earth. In cases where the funnel is held above the metal receiving tank or the container, and when a considerable quantity of gasoline is passed through the chamois skin, a comparatively large charge accumulates from the funnel, and if the funnel should come in contact with the container, the charge is drawn off, resulting in a spark which, from reports received, has ignited gasoline vapor.

"A charge of static electricity was obtained by placing a chamois-lined funnel inside of a glass funnel, insulating the metal funnel from the container, which was insulated from the ground by being placed upon a rubber-covered table. A copper wire connected the glass funnel with an electroscope. Upon pouring gasoline through the chamois-lined funnel a charge of static electricity was generated, as indicated by violent separation of the leaves of the gold-leaf electroscope. When the container and funnel were grounded, no charge of electricity was generated. In damp, warm weather there is less danger of generating the charge than when the humidity is low."

It is evident from the above that it is preferable to strain the gasoline through a wire cloth and at all times to have the funnel, container and receiving tank in contact and properly grounded.

Media, Pa. R. A. H.

Removing Scale from Radiator

Editor THE AUTOMOBILE:—Please give complete directions for removing scale and other deposits from the radiator of an automobile.

I have seen general directions, but they never seem to be complete. If sal soda or soda ash is used, please state how much per gallon and under what conditions to use same, how long it should be left in the radiator, etc.?

Uniontown, Pa. E. T. P.

—Scale can be removed from radiators by using a saturated solution of common washing soda and water. Thoroughly flush the radiator out with the solution then clean with fresh, pure water. A mixture of ordinary washing soda in which 4 oz. is used to the gallon of water will do the work properly.

Horsepower and Pulling Power

Editor THE AUTOMOBILE:—Suppose two automobiles each weigh 2600 lb., one having a horsepower of 25 and the other 26; about how much more weight would the 26 hp. one move at usual driving speed than the 25-hp. car? Would it be as much as 500 lb.?

Rochester, N. Y. W. A. P.

—Assuming that both cars had the same frictional losses in transmission of power and had the same gear reduction, the ratio of pulling power under most circumstances would be 25 to 26. It is impossible to give definite figures.

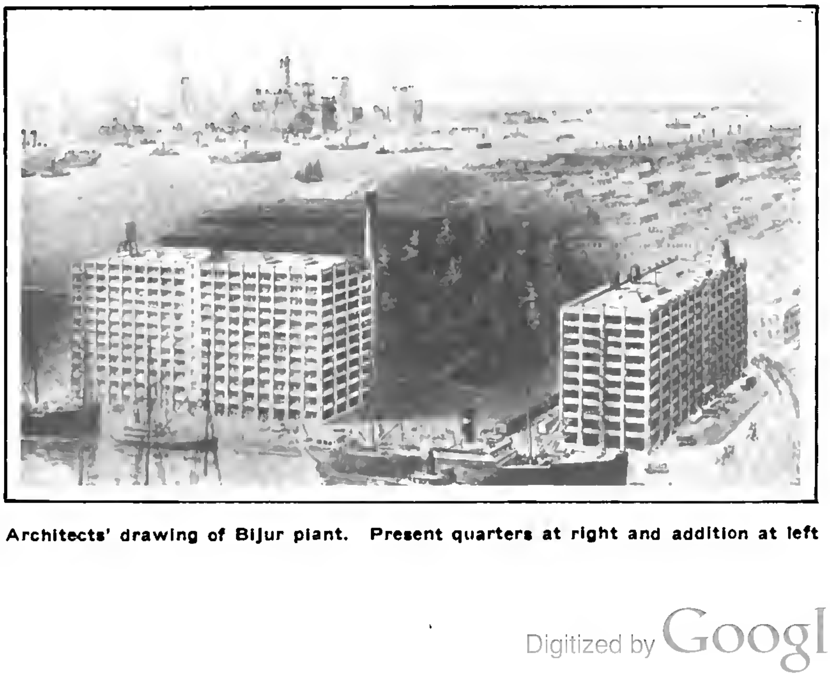
Correct Timing of Chandler

By a typographical error in giving the firing order of the Chandler six in The Rostrum last week, the fifth cylinder was mentioned twice. The correct firing order is 1-6-3-5-2-4.

Bijur Adds Twelve-Story Plant

NEW YORK CITY, April 8—The Bijur Motor Lighting Co., Hoboken, N. J., is erecting a fireproof twelve-story and basement addition to its plant, which will be 265 by 85 ft., giving 260,000 sq. ft. of floor space. The construction is steel, concrete and glass, and the building is located about 150 ft. from the company's present plant which will be continued. It is expected that the addition will be occupied by July. Offices will be on the top floor and a progressive system of manufacture will be used, the materials passing downward until emerging as complete machines on the ground floor. There are two passenger and two freight elevators and an automobile elevator.

It is probable that the spacious basement of the new building will be utilized for a garage which will be of the most up-to-date type. Shipping facilities of the Bijur company plant and its addition are excellent.



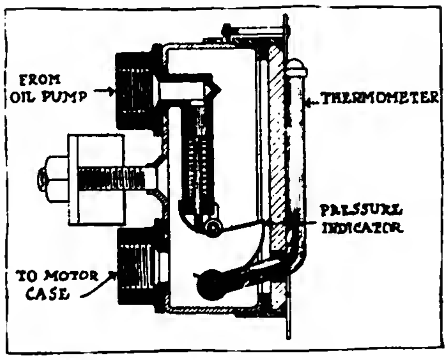
Architects' drawing of Bijur plant. Present quarters at right and addition at left

ACCESSORIES

Climax Motor Indicator

THIS device combines a pressure gage, motor indicator and oil sight feed and is mounted on the dash. The makers rely on the lubricating oil of the motor for registry, referring to it as "the blood of the motor," as it comes into contact with all the working parts. No matter how high the pressure may run when the motor is cold, the instrument is not affected by the additional strain imposed on it by such conditions, according to the manufacturers. The oil gage enables the driver of the car to see whether or not the oil is circulating properly and the indicator registers the temperature of the oil on the thermometer as it passes through the gage. The importance of this is that, should the quantity of the oil in the motor diminish, a rise in temperature would be indicated on the thermometer, as would also poor circulation of the cooling water, a late spark or too rich or too lean a mixture. When the thermometer registers "no higher" than the atmospheric temperature, the oil is not working. The indicator sells for $5.—Climax Motor Devices, Cleveland, Ohio.

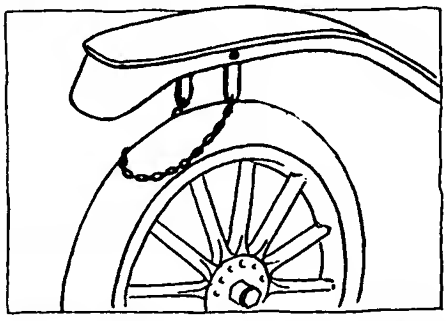
Climax motor indicator for dash mounting



Section through Climax indicator

Wild's Tire Guard

This guard consists of a chain resting on the tire, its purpose being to dislodge nails, sharp stones and similar objects before they can penetrate far enough to do serious damage. The chain attaches to fender brackets. Price, $1.25 each.—Motor Car Supply Co., Minneapolis, Minn.



Wild's tire guard for removing nails, etc.

Goodyear Tire-Saver Kit

This kit is designed to enable car owners to increase the mileage obtained from their tires by applying first-aid measures before serious troubles develop. It contains a rim cut patch; an outside protection patch; a No. 4 self-cure patch; a 2-oz. can of repair tape; a 2-oz. can of patching cement; a 2-oz. can of tire putty; a pressure gage and a tube of French talc. For tires of 3 and 3½-in. diameter, the kit sells for $3.50; for 4 and 4½-in., $3.75, and for 5 and 5½-in., $4.—Goodyear Tire & Rubber Co., Akron, Ohio.

Rives Never-Slip Pedal Pads

These rubber pedal pads are designed to obviate all tension, shock and wearing of the shoe sole, also to prevent the foot from slipping in operating the pedals. No. 1 is made for Fords and will fit all oval pedals from 1¾ by 3¾ in. to 1⅞ by 3½ in. No. 2 fits all pedals having flat or curved surfaces measuring from 2¼ by 3¼ in. to 2¾ by 3¾ in. No. 3 is for pedals with large oval surfaces from 2¼ by 4 to 2¾ by 4½ in. No. 4 is for Maxwell cars. No. 5 for Mitchell and Dodge Bros., being for pedals with round surfaces from 2¼ to 2¾-in. diameter. No. 6 fits pedals with long and narrow rectangular or oval surfaces from 1½ by 3¼ to 1¾ by 4 in. No. 7 is for pedals with flat or curved surfaces from 2⅜ by 4¼ to 2¾ by 4¾. The pads sell for $1 per set for all models.—George H. Rives Mfg. Co., New York City.

Rives adjustable rubber pedal pads. These are made for all makes of cars

Kilborn-Sauer Lamps

Among the many lamps in this line is a distinctive little projector only 3½ in. diameter which sells for $3.50. It has a one-piece cylindrical body, a universal joint so that the light can be projected in any direction, a handle at the back and a substantial bracket for attachment to the windshield; a dash switch goes with each lamp. A larger spotlight is made in two models, 6-in. and 8-in.; the former costs $6 and, with 4-in. mirror, $7, and the latter $9 and $10. In this lamp also the body is in one piece, but it is of the more conventional parabolic form. A Ford set of 2 side lamps and a tail lamp is offered at $5; the feature of the side lamps is that they throw light on the running-boards without shining in the eyes of the driver. A sufficient length of flexible cable is furnished with each set.—Kilborn-Sauer Co., Fairfield, Conn.

Two of the Kilborn-Sauer spotlights

Motor-Aid

A fan wheel with a heavy flywheel rim is installed in the exhaust line so that the gases impinge upon the blades of the fan and cause it to rotate rapidly. The strong exhaust impulses give the wheel a high rotative speed and this is maintained by the flywheel so that the fan acts as an exhauster between impulses, creating a partial vacuum in the exhaust pipe and assisting in clearing out the products of combustion. The makers claim better and more economical motor operation due to reduction of back pressure. Price, $30.—Motor Aid Co., Chicago, Ill.

Stock Versus Custom

EVERY man knows that the reason the average American automobile is such excellent value for its price is because it is a stock product. Because it is reproduced in quantities without any difference between one car and the next of a particular series. It can be but a fraction of the price that would be needed if each car were of different design.

We have to-day stock cars of enough sizes, qualities and types to suit all classes of buyers. The custom built chassis has ceased to exist and the custom built body is asked for only by those who wish individuality for its own sake, who must have something different from their neighbors and are ready to pay the large price demanded. The custom built car came first and is still selling in large numbers, larger than ever probably, but the stock car grew alongside and multiplied at an immense pace so that the custom built car has become an insignificant percentage of the total.

Standardization, of the sort which has been carried out by the S.A.E., has the same effect upon the industry as a whole as has concentration upon one type of chassis upon the business of a single manufacturer. Without standardization of detail the stock cars of to-day would be quite considerably more costly.

The individual manufacturers effected standardization within their own factories as soon as ever they commenced to concentrate upon real manufacturing as opposed to car building. The S.A.E. standards begin where the individual manufacturer leaves off and carry the process on, so that the steel mill and the parts maker are saved the necessity of "building" their product for each manufacturer of automobiles. Over the whole range, from the melting of the ores to the shipping of the completed car, every saving in cost that can be made reaches the final buyer.

Work Only Begun

The standardizing work has but begun; it will never be completed as long as knowledge progresses, for new discoveries will demand new consideration. For the next 10 years automobile standardization will go on increasing in importance, will need more work and more money for its successful accomplishment. It is just about to expand out of America and to spread over the earth as the American automobile is spreading and acting as the missionary.

The Differential

THE suggestion that the differential may cease to be a part of automobile makeup will come as a shock to a good many engineers who have always thought it an essential. On the short wheelbase cars of the early days it was essential and, giving little trouble, few have given it much thought. Always it has been realized that the differential had a bad fault in that the power goes to the wheel with the least traction, and if one wheel has no traction, as when in a mud hole, then that wheel spins and the car comes to a stop. There have been many attempts to overcome this. One of the earliest was to fit each rear wheel with an overrunning clutch so that the outer wheel was driven when on a curve, the solid driveshaft turning idly within the inner wheel. This worked very well, but a car of this type could not be reversed without rather complicated locking mechanism for the clutches.

Many Alterations

Next attempts were made to devise an overrunning clutch which would act automatically both forward and reverse without hand control; then came differentials with high internal resistance, and finally solid axles without differentials. To-day all three of these types exist side by side and the engineers are becoming sufficiently interested to investigate them seriously. The outcome may easily be a distinct improvement in the conventional car by lessening the danger of skidding and increasing tire durability.

The ideal is to have a differential for some conditions and not to have one for others, while the wheel that has the least traction should receive the least power. Of the two wheels the one best able to transfer the tractive force to the road should get most of that force and the wheel with little traction not enough to make it spin.

328,366 Cars Built by Five Cities in Three Months

During January, February and March, Detroit, Toledo, Flint, Jackson and Lansing Broke All Records—238,076 of Total Built in Detroit Plants

DETROIT, MICH., April 8—Automobile production for January, February and March of this year has reached the total of 328,366 cars from the five cities of Detroit, Toledo, Flint, Jackson and Lansing, all in the great production zone surrounding this city. This increase for the first quarter has no precedent in automobile manufacturing annals. During the first three months of 1915 all of the automobile factories in the country built approximately 106,000 machines. The Detroit zone alone has tripled the production of the entire country during the first quarter of this year.

Detroit Plants Lead

Of this total of 328,366 machines built in these five cities, Detroit factories lead with 238,076 cars, according to a careful census made by THE AUTOMOBILE. This leaves 90,290 machines for the other four cities which house such large factories as Overland, Buick, Reo, Chevrolet, Oakland and Oldsmobile.

Figuring the average overall length of the 238,076 cars built in Detroit in the first three months of 1916 to be 12 ft., these cars would form a line 540 miles long if they were placed end-to-end. In other words, such a line would extend in a double line from Detroit to Chicago.

Naturally Ford leads in these almost staggering figures of production increase in this production zone. There were 149,005 Fords built during the three months. March was the greatest month in Ford history, there being 58,329 cars built at the home factory and the several assembly plants. Ford figures for the three months are: January 44,365; February 46,311; March 58,329. These figures almost eliminate any doubt as to the probability of 500,000 Ford cars being built during the fiscal year.

Overland Is Second

Following Ford comes Overland, the second largest producer of automobiles in the world. This Toledo factory has made extraordinary progress in production during the first three months of this year as compared with the corresponding months last year. January, February and March, 1916, resulted in the manufacture of 47,465 Overland cars, 12,393 in January; 15,292 in February and 19,780 in March. Compare this with the total for the first three months of 1915, which was 17,245 automobiles. In other words, March, 1916, exceeded the entire production of the first three months of 1915 by over 2000 cars and the entire quarter is nearly three times ahead of last year's first quarter.

Carload Shipments

January	12,000
February	21,502
March	28,600

Car Production

Ford

January	44,365
February	46,311
March	58,329

Overland

January	12,393
February	15,292
March	19,780

Many other factories have shown proportionate increases. Take the Saxon, for example. Last year's first quarter showed a combined production of 2591 Saxons, but for the present quarter 6391 machines carried the Saxon name. March just passed resulted in the building of 2604 Saxons, thus exceeding alone the record of the first three months of 1915.

Production's Rapid Increase

Everywhere you go you are met with information of unprecedented growth in production among the well-known companies.

Studebaker indicates an increase of 100 per cent over last year's first quarter. Packard declares that its production has stepped up 300 per cent.

Cadillac has shipped 26,563 eights since it started to make them, a wonderful showing for a high-priced car, as prices are reckoned these days. There are some 400 Cadillacs awaiting shipment now, and they would have been on the road long ago had there been freight cars in which to ship them.

Reo has been enjoying a wonderful growth in Lansing, and shows greatly increased output.

Oakland states that its production is 400 per cent better than for the first quarter of 1915.

March showed the best record for manufacture and shipment of cars in the history of the Paige-Detroit Motor Car Co., production facilities having been increased to 175 cars a day.

Maxwell is making over 300 cars a day now, and is attaining a monthly output of about 8000.

If it were possible to divulge the actual output in all of these cases, the public would be astounded at the figures. These give a good indication of the great advance which the industry is making in nearly all directions.

Many Handicaps

When you consider that a number of things of a more than passing seriousness have been confronting the makers this year, the results are all the more astonishing. Never has the tie-up of freight cars been so acute; never in the history of the business have raw materials been higher or more difficult to obtain; gasoline is high; prices in a great many instances have had to be raised on the cars as a result of materials conditions; labor of the right kind is scarce.

Yet with all their problems, the factories are striving in every way to meet the demand for cars. Higher prices do not seem to mitigate against the vehicles in any way, for the average purchaser seems willing to pay slightly more rather than have the quality of the car curtailed. All seem to realize the unusual market conditions and understand the reasons for increased prices.

Freight Situation Easier

Although the National Automobile Chamber of Commerce reports no betterment of the freight car situation, there are some who feel a bit easier over it, although nothing very beneficial has developed. The removal of certain embargoes to points in the East have helped somewhat, and with spring coming on, it seems likely that the congestion will automatically be bettered, at least slightly. March was the record shipping month so far in the history of the industry, the carload shipment statistics for 1916 being given herewith.

J. & D. Tire & Rubber Co. Formed

H. O. Smith Completes $500,000 Organization — Factory in Charlotte, N. C.

CHARLOTTE, N. C., April 7—The J. & D. Tire & Rubber Co. was organized here to-day for the manufacture of pneumatic tires for automobiles. The president of the organization is Harold O. Smith, who started in the rubber business in 1893 as one of the founders of the Indianapolis Rubber Co., which concern later became the G. & J. Tire Co. of Indianapolis, of which Mr. Smith was president. Mr. Smith was in the tire business approximately thirteen years until 1906, when he formed the Premier Motor Car Co. of Indianapolis, of which he was president until a year ago.

It has been known for more than a year that Mr. Smith has been arranging for the formation of the tire organization, which was completed to-day. Charlotte, N. C., was selected as a factory location because it is a favorable center for satisfactory labor for this class of work and offers good facilities for the necessary factory power.

The J. & D. Tire & Rubber Co. has been capitalized for $500,000 and will manufacture only one grade of pneumatic tire, which will be built in all the necessary tire sizes. It is expected that the trade name for these goods will be J. & D. Production will be started by July. This is possible, as Mr. Smith obtained options on tire machinery last October. Already plans have been drawn up for the erection of a new factory in this city and work has commenced. The factory contracts are such that production will be possible by July.

Mr. Smith has been elected president of the organization and has connected with him some most influential interests and men strongest financially in this section. To facilitate selling arrangements some of the largest distributing interests in the country have been taken into the organization, so that J. & D. tires will be sold largely to the company's own organization. Associated with President Smith are: Thomas J. Northway, Rochester, N. Y., vice-president; L. A. Falger, Charlotte, N. C., secretary; C. C. Coddington, Charlotte, N. C., treasurer. Directors, in addition to the officers, are: Harry S. Leyman, Cincinnati, Ohio, D. H. McColough and E. Thomonson.

22,773 Canadian Fords in 8 Months

FORD, ONT., April 7—From the beginning of the 1916 fiscal year of the Ford Motor Co. of Canada, Ltd.; that is from Aug. 1, 1915, to April 5, 1916, or a period of about eight months, the Canadian Ford company made and shipped 22,773 Fords, as compared with 7443 during the corresponding period of the 1915 fiscal year. The total production for the 1916 fiscal year is expected to be 40,000. During March 4500 cars were shipped, of which 1681 went to foreign countries. Of the total of 22,773 cars made, 12,442 were sold in the Dominion and 9569 went to foreign countries. March 29 the company had its biggest day of production, when 312 cars were made and shipped, of which 120 were for export.

Auburn and Lozier Raise Prices

NEW YORK CITY, April 8—The Auburn Automobile Co. has advanced the list price on its Model 6-38 from $1,050 to $1,085, effective April 1. Models 4-36 at $895 and 6-40A at $1,375 remain the same for the present.

A $100 increase will be made on the Lozier four, which will sell after April 15 for $1,695. For the time being there will be no raise in the price of the six selling at $2,775.

1,111,623 Champion Spark Plugs in March

TOLEDO, OHIO, April 10—All production and sales records of the Champion Spark Plug Co., Toledo, Ohio, were broken during the month of March, just past. In that month were produced 1,111,623 complete spark plugs and 167,420 assembled porcelains, while sales were 1,137,299 complete spark plugs and 94,277 porcelains.

However, the Champion Spark Plug Co. states that there will be a 100 per cent increase in production when the new six-story addition is finished.

4460 Overlands in One Week

TOLEDO, OHIO, April 10—During the week ending April 8, the Willys-Overland Co., established a new shipping record, a total of 4460 Overland cars being shipped. This is at the rate of 743 cars for each of the six working days and better than thirty cars per hour, on a twenty-four-hour schedule.

George Heads Napoleon Co.

NAPOLEON, OHIO, April 6—The recently incorporated Napoleon Auto Mfg. Co., this city, has elected A. O. George as president, F. P. Diemer and G. M. Donnelly, vice-presidents; O. A. Diemer, secretary and treasurer, and C. E. Donnelly, general manager.

The company will assemble a four-cylinder 25 hp. chassis at the start, and later on will produce a finished car. The Morningstar plant in this city has been secured.

$5,000,000 Perlman Stock Issue

Half of $10,000,000 Capital Offered to Public at $120 —Is Over-Subscribed

NEW YORK CITY, April 10—Stock of the $10,000,000 Perlman Rim Corp., recently organized here to manufacture the Perlman demountable rim, is to be offered to the public. Subscriptions to the underwriting of the 50,000 shares, no par value, out of 100,000 shares of the Perlman corporation, are being received by J. S. Bache & Co. at $120 a share. Underwriters will have the privilege of withdrawing half of their stock, which must be withheld from sale for six months.

Only $5,000,000 of the $10,000,000 stock was offered for subscription, the remaining $5,000,000 being retained by Messrs. Kaufman, Durant and Perlman, who jointly own the entire amount. Subscriptions received were nearly double the amount of the issue so that it was necessary to reduce the allotments.

The directors of the Perlman Rim Corp. are L. G. Kaufman, president of the Chatham & Phenix National Bank; W. C. Durant, president of the Chevrolet Motor Co.; L. H. Perlman; L. B. Rosenberg, banker, and Christian Girl, president of the Perfection Spring Co. Mr. Perlman is president of the new company and Mr. Girl vice-president. The executive committee is composed of L. G. Kaufman, chairman; W. C. Durant and L. H. Perlman.

The Perlman Rim Corp. will have 100,000 shares of stock of no par value, and will have no bonds or debt. The company will start with $3,000,000 cash.

Within ninety days it is expected that the output of the company will be established at the rate of 1,000,000 sets of rims a year. Earning power is estimated on this basis at between $2,500,000 and $3,000,000 per annum.

The application of the Standard Welding Co. for a temporary suspension of the injunction secured by the Perlman interests has been withdrawn.

Goldie Is Columbia Factory Manager

CLEVELAND, OHIO, April 6—R. J. Goldie has become factory manager of the Columbia Axle Co., this city. For the past two years he has been the works manager of the Metals Products Co. Previous to his connection with the Metal Products Co. he was with the Chalmers Motor Co. for five years.

Knight Tire Plant Reopens

CANTON, OHIO, April 6—The Knight Tire & Rubber Company, this city, closed since last week on account of a shortage of rubber, has reopened.

Bock Bearing Co. Reorganized

New $1,650,000 Bock Taper Roller Bearing Co. Takes Over Plant

TOLEDO, OHIO, April 6—Retaining the old name, a new $1,650,000 corporation has taken over the plant of the Bock Bearing Co., on Phillips Avenue, this city. The following officers have been elected: President, W. E. Bock; vice-president, Eugene Rheinfrank; secretary and treasurer, C. H. Clement.

The officers, with M. H. Murch of Cleveland and J. E. Dunipace of Toledo, comprise the directorate.

The new company was incorporated about a week ago under the name of the Bock Taper Roller Bearing Company.

Of the stock issue of the new corporation, $1,200,000 will be common and $450,000 will be 7 per cent cumulative preferred. The capital of the old company was $212,500 common and $150,000 preferred.

As part consideration in the transfer of the old company to the new, holders of old stock will exchange share for share of new stock, and holders of old preferred will receive two shares of new common for one of preferred.

The plant of the Bock Bearing Company will be tripled in its capacity. Work will be started immediately. The present output of bearings is 1200 a day. With the new facilities as planned, the daily output will be 3000 bearings. The company at present employs 200 men.

Briscoe Motor Corp. Leases Fuller Buggy Plant

JACKSON, MICH., April 7—The Briscoe Motor Corp. has leased the plant of the Fuller Buggy Co., and will probably use it as its final assembly plant. Business has been increasing right along for the past few months, and more manufacturing room has become a necessity. As it will take too much time to build additions it was found advisable to lease buildings where it will only require a few weeks to put them into operative condition.

Clyde Truck Plant in L. I. City

NEW YORK CITY, April 6—The Clyde Motor Truck Co., which was incorporated last month in Delaware with a capital of $750,000, of which $250,000 is preferred and the balance common stock with a par value of $10, has acquired a plant in the automobile district of Long Island City, near Woodside. It is expected that deliveries on its 1-ton truck, selling at $1,000, will begin in July. The purpose of the company is to assemble this truck exclusively. It is equipped with a Buda engine.

M. C. Swartz, a real estate operator, is president of the company; W. F. Melhuish, formerly of the White Motor Co., is vice-president; J. F. Mason is secretary, and E. E. Vreeland, an advertising man, is treasurer. Among the directors are P. R. McLean, a director of Fraser & Best, Ltd., Australian exporters and importers; Walter Kenlon, son of Fire Chief Kenlon, and P. J. Holdsworth.

White Motor Co. Elects Officers

CLEVELAND, OHIO, April 10—At the annual meeting of the White Motor Co., the capital stock of the White Co., which is owned by the White Motor Co., was reduced from $5,000,000 to $500,000. The White Co. will become the selling organization for White trucks and automobiles.

The following board of directors was elected at the annual stockholders' meeting of the White Motor Co., April 8: Windsor T. White, Walter C. White, A. R. Warner, E. W. Hulet, Otto Miller, M. B. Johnson and J. R. Nutt, of Cleveland; and J. H. Harding, A. M. Hall, 2d., Theodore Roosevelt, Jr., and E. R. Tinker, of New York.

At the first meeting of the directors, the following officers of the White Motor Co. will be elected: Windsor T. White, president; Walter C. White, first vice-president; E. W. Hulet, second vice-president; M. B. Johnson, chairman of the board; Otto Miller, treasurer; A. R. Warner, secretary and assistant treasurer.

The White Motor Co. is having quite a little trouble in securing cars for the shipment of trucks to New York for export. As a result a large number of trucks have accumulated in its yards. The traffic department believes that if the railroads would increase their own charge for holding cars over time from 45 cents to $1 per day, shippers would experience relief sooner than through the increased demurrage charge which the roads are now allowed to charge shippers.

Covert Incorporates for $1,000,000

LOCKPORT, N. Y., April 7—The Covert Gear Co., this city, has been incorporated with a capital of $1,000,000, to manufacture trucks, tractors and other vehicles. The incorporators are W. W. Armstrong, P. A. Clum, B. V. Covert.

Schwalbach Leaves Perlman Interests

NEW YORK CITY, April 10—Alexander Schwalbach, formerly with the J. S. Bretz Co., and more recently connected with the development of the Perlman Rim Corp., has severed his connection with the latter. Mr. Schwalbach has not as yet made any plans for the future.

G. M. C. Buys 35-Acre Tract

To Provide for Possible Concentration of Cadillac Co.'s Plants

DETROIT, MICH., April 11—*Special Telegram*—Thirty-five acres of land have been purchased by the General Motors Co. in the northeastern part of Detroit, and adjoining a 58-acre tract which was acquired three years ago by the company. This gives a frontage on the railroad of 4600 ft., with shipping facilities on the Grand Trunk, Detroit Belt Line and Michigan Central railroads.

President C. W. Nash stated to-day that the property had been acquired to safeguard the Cadillac Motor Car Co. in the event that the company should deem it advisable to concentrate its plant at one place. At the present time Cadillac plants are situated in several parts of the city and such a site as the General Motors Co. has provided would mean complete concentration at the one location. The body factory is now several miles from the main works, and the remarkable growth of the Cadillac company has meant many additions to the parent plant.

Peerless Truck Re-elects Directors

NEW YORK CITY, April 11—All the present members of the Peerless Truck & Motor Corp. were re-elected at the annual meeting in Richmond, Va., April 4. The election of officers will take place April 14. The board of directors is composed of the following members: C. V. Rich, vice-president of the National City Bank and president of the National City Co.; E. R. Tinker, Jr., vice-president Chase National Bank; P. J. McIntosh, 26 Broadway, president of the General Gas Appliance Co., director of Montreal Public Service Corp., and other Canadian companies; B. G. Tremaine, F. S. Terry, identified with General Electric Lamp Works at Cleveland; P. D. Wagoner, president of the General Vehicle Co., Long Island City; L. H. Kittredge, president of the Peerless Motor Car Co., Cleveland; Harrison Williams, identified with Cleveland Electric Illuminating Co., as chairman of board; E. W. Hargen; T. W. French, vice-president of the Peerless Motor Car Co.; and Harvey Hooke.

Haas Joins Monroe Co.

FLINT, MICH., April 10—L. D. Haas, sales manager of the Chevrolet Motor Co. of Michigan, has resigned to become sales manager of the Monroe Motor Co., this city. F. K. Lane will succeed Mr. Haas at the Chevrolet plant. He is at present manager of the Chevrolet branch at Dallas, Tex.

Premier Organization Completed

Officers, Directors and Department Heads Selected—$2,500,000 Capital

INDIANAPOLIS, IND., April 10—The organization of the Premier Motor Corp., this city, has been completed and that concern is now ready for business. The corporation starts with a capital stock of $2,500,000 and large production of quality cars is the intention.

The officers are as follows: J. C. Flowers, president; F. E. Smith and E. W. Steinhart, vice-presidents; C. F. Jensen, secretary; and H. L. Thompson, treasurer.

The directorate consists of George Woodruff, president of the Illinois Bankers' Assn. and president of the First National Bank, Joliet, Ill.; H. L. Thompson, secretary of the Gerlach-Barklow Co., Joliet, Ill.; T. R. Gerlach, vice-president of the Gerlach-Barklow Co., Joliet; C. F. Jensen, president of the Vanguard Mfg. Co., Detroit, Mich.; F. W. Woodruff, vice-president of the First National Bank and vice-president of the Woodruff Trust Co., Joliet, Ill.; J. C. Flowers, Joliet, Ill., and E. W. Steinhart, Indianapolis.

The department heads are P. D. Stubbs, director of sales; Homer McKee, director of advertising; P. W. Tracy, director of purchases and stores; E. G. Gunn, chief engineer; F. P. Nehrbas, factory production manager; C. S. Crawford, associate engineer, and J. L. Yarian, associate engineer.

The entire plant formerly occupied by the T. B. Laycock Co., with 300,000 sq. ft. of floorspace, has been rehabilitated.

Linsden, Goodrich European Manager, Here on Visit

NEW YORK CITY, April 8—Arthur E. Linsden, European manager of the B. F. Goodrich Co., Akron, Ohio, arrived in America last week on a short business trip. Mr. Linsden has charge of the Goodrich Paris factory, which was opened some five years ago. He is an American and well known in many car circles.

Studebaker Elects Officers

SOUTH BEND, IND., April 10—J. M. Studebaker, Sr., Col. George M. Studebaker and C. C. Hanch were re-elected to the directorate of the Studebaker Corp. at the annual meeting of the stockholders held in the office of the company in Jersey City, N. J. Later, in New York, the board of directors of the corporation held its annual meeting and elected officers for the ensuing year besides appointing the regular committees. J. M. Studebaker was re-elected honorary president; Frederick S. Fish, chairman of the board, and A. R. Erskine, president. The other officers chosen are: L. J. Ollier and J. G. Heaslet, vice-presidents; C. C. Hanch, treasurer; C. D. Fleming, W. P. Shillington and F. Studebaker Fish, assistant treasurers; A. G. Rumpf, secretary; John B. Marsh, assistant secretary; Frederick P. Delafield, counsel; George A. Fulmer, cashier; H. E. Dalton, general auditor. The executive committee is composed of Frederick S. Fish, Henry Goldman, A. R. Erskine, H. H. Lehman, Frederick P. Delafield and Col. George M. Studebaker; the finance committee of Frederick S. Fish, A. R. Erskine, Col. George M. Studebaker, James C. Heaslet and C. C. Hanch.

April 21 Standardization Day

CLEVELAND, OHIO, April 12—Large attendance is expected for the meeting of the standards committee of the S. A. E., which takes place here next week. April 20 will be a get-together day, there being several division meetings scheduled and the general meeting will begin at 10 a. m. April 21. The Cleveland section is arranging a most worthy entertainment for the visitors in the form of a paper and discussion on some of the most vital problems of carburetion. This will follow the meeting on April 21. The Statler Hotel has been chosen as headquarters and the management have placed a suitable meeting room at the disposal of the committee, these arrangements having been made by J. G. Utz, Perfection Spring Co., Cleveland, chairman of the miscellaneous division of the standards committee.

Smith and Vincent to Speak to Detroit S. A. E.

DETROIT, MICH., April 10—Two of the best known members of the automobile industry in this city will be the speakers at the next meeting of the Detroit Section of the Society of Automobile Engineers. Paul Smith, vice-president of the sales division of the Chalmers Motor Co., will talk on the subject of Interpreting the Public to the Engineer, while vice-president of engineering, J. G. Vincent, of the Packard Motor Car Co., has chosen as his subject Motors of the Air. The gathering, which is expected to draw a record-breaking attendance, will be held Monday, April 17, in the convention hall of the Hotel Pontchartrain.

The Detroit section's nominations for officers are: D. McCall White, chief engineer of the Cadillac Motor Car Co., to succeed George W. Dunham as chairman; O. E. Hunt, vice-chairman; W. C. Rands, treasurer; Bernard C. Koether, secretary; K. W. Zimmerschied, nominated as member of the national nominating committee.

S. A. E. Reservations Going Fast

Plans for Summer Cruise of Society Taking Definite Form—Papers Good

DETROIT, MICH., April 10—The 1916 meetings committee in charge of the summer cruise of the Society of Automobile Engineers has already made 147 reservations for members and guests for this outing. The S.S. Noronic has a total accommodation for 550 and, with over one-quarter of this taken up in a fortnight after the matter was first placed before the members, it seems certain that the capacity of the boat will be sold well before June 1.

For the convenience of members taking the cruise, arrangements have been made for the S.S. Noronic to stop at Sarnia, Ont., on the return trip Friday, June 16, so that those desiring to take railroads from this point can do so. Detroit hotels will be crowded the week of the cruise because of other conventions, and for the convenience of those members taking the trip the Northern Navigation Co. has agreed to let those members stay on the steamship Friday night who cannot secure accommodations. No meals will be served Friday night on the boat.

K. W. Zimmerschied, chairman of the standards committee during the past year and who is chairman of the papers committee, has already made extensive progress, and the subjects presented will be of a high engineering caliber. The subjects will cover the entire engineering field, including such pertinent subjects as design of agricultural tractors, design of aeroplane motors, problems connected with motor trucks in military transport. and possibilities of kerosene engines in motor vehicles. The question of carburetion, so pertinent to-day, will receive adequate attention. Practically one session will be given over to papers and discussions on high-speed motors. Motor fuels will be considered at another session. Howard Coffin, member of the Naval Consulting Board, will present a paper on preparedness. J. E. Hale of the Goodyear company will read a paper on straight side vs. clincher type tires. C. H. Eason of the Hyatt Roller Bearing Co. will read a paper on engines for foreign tractors. H. D. Church of the Packard company will have a paper on motor trucks, and E. A. Nelson on pressed steel construction in automobiles.

N. G. E. A. Opens Exchange Dept.

LAKEMONT, N. Y., April 11—An interesting method for assisting in the securing of the most efficient distribution of stock has just been adopted by the National Gas Engine Assn. Secretary Brate has just issued to members of the N. G. E. A. the following bulletin:

"At this time when it is very hard to obtain materials which go into the construction of internal combustion engines, together with slow deliveries and high prices, we are pleased to announce the opening of an Exchange Department.

"This is just what the words imply. Smith & Co. have an over-stock of crankshafts, etc., which Brown Bros., if they only knew about, could use to good advantage; while Brown Bros. have a dead stock of cold-rolled shafting which is the very thing Smith & Co. have been trying to get delivery on. Both clean up their dead stock; both get materials they are in great need of. A shut-down has been prevented. A customer has his order filled on time.

"Send to this office at once a list of your dead stock.

"Let us have your list of requirements.

"Just another form of N. G. E. A. coöperation.

"No charge, of course, to members for this service."

Tractor Co. May Occupy Crawford Plant in Streator

STREATOR, ILL., April 7—Representatives of the Auto Tractor Co. of Chicago are negotiating with the Commercial Club of Streator for the occupancy of the abandoned Crawford car plant to be utilized in the manufacture of a new device to be attached to an automobile by which it is possible to utilize the car for field work upon a farm, such as plowing, disking, harrowing, sowing, harvesting, or other lines. It is claimed by the inventor that with the use of this device the road speed of the car is diminished, while the pulling power of the engine is proportionately increased. The outfit consists of a pair of tractor wheels which are attached to a steel frame. Shafts are provided for transmitting the power from the automobile wheels to the speed reduction gearing and traction wheels. A radiator of sufficient cooling capacity to offset the slower speed is furnished.

Kelley Buys Bromfield & Field

NEW YORK CITY, April 11—Martin V. Kelley, president of the Toledo advertising company bearing his name, has purchased outright the advertising business of Bromfield & Field, this city.

Detroit Tube Co. to Expand

DETROIT, MICH., April 10—The Detroit Seamless Steel Tube Co., which makes tubing for automobiles and tractors, now located at 841 Jefferson Avenue, has purchased twelve acres of ground at Fort and Waterman Streets, and will erect a new plant, where it is expected, at least 2000 men will be employed.

No Shortage in Crude Petroleum

Trade Commission Reports 100,021,790 Gal. Held in February

WASHINGTON, D. C., April 10—The Federal Trade Commission to-day submitted to Congress a preliminary report on the gasoline situation. The commission finds there is no shortage in the supply of crude petroleum; in fact, the supply on hand in February, 1916, was 31,000,000 gal. in excess of that available in February, 1915. In the tables submitted with the report the commission shows that gasoline rose 4.88 cents a gallon in the Middle West refineries and 5.50 cents a gallon in eastern refineries. This is but a fraction of the rise to consumers. The report shows that while gasoline was increasing an average of a little over 5 cents a gallon at the refineries, crude oil was rising but 1.17 cents at western and 1.55 at eastern refineries.

Crude Supply Plentiful

The commission found that instead of there being a lesser supply of crude petroleum on hand now, there were 100,021,790 gal. held in February, 1916, as against 69,323,242 in February, 1915; that production of gasoline increased from 76,663,537 gal. in January, 1915, to 97,506,217 in December, 1915; that 15 per cent of the total production is exported.

The effect of decreased production in the Cushing field in gasoline terms is given in a footnote, which says the gasoline content of oil from the Cushing field fell from 96,000,000 gal. in April to 36,000,000 in December. The gasoline content of all the oil produced in the United States decreased during the year. The estimate of the year's total gasoline content for all the oil in the country was 1,892,500,000 gal.

S. O. Produced 60 Per Cent

Standard Oil companies, the tables show, produced about 60 per cent of the year's gasoline output. Their total was 681,750,000 gal. and that of the independents 400,000,000 in round numbers. Gasoline stock held by refineries decreased steadily from last May, when the total is put at 292,000,000 gal., to December, with a total of only 152,000,000. Stocks increased from the first of the year to May. Price ranges show that the price charged by the independents averages about 1 cent higher than Standard Oil prices. The Standard was selling gasoline f.o.b. its refineries at 7.82 cents a gallon Jan. 1, 1915, and the independents were charging 8.38 for the same grade. There was little change until August, when the Standard price went to 7.88 and the independent price dropped to 8.02. Four months later, in December, the Standard was charging 12.84 and the independents 13.07.

A digest of the preliminary report follows:

"The Federal Trade Commission has for some time been engaged in an investigation of the entire petroleum industry. The extraordinary advance in gasoline prices, however, together with numerous complaints of discrimination received, has made it evident that immediate investigation of the gasoline situation is most urgently needed.

"The following steps are now being taken in the active conduct of this investigation:

Gathering Statistics

"First, crude-oil production is being studied, and the most accurate information available concerning quantity of production, storage and prices is being gathered. In this connection, every important refinery in the United States has been asked to report the kind and quantity of oil used, the price paid, and the stocks of crude held at various times during the year 1915.

"Second, refiners making over 95 per cent of the total production of the country are reporting the following facts concerning their gasoline business for each month of the year 1915: Quantity purchased, quantity produced, quantity sold, and quantity in stock; prices received f.o.b. refinery and at tank-wagon stations. A force of accountants is now in the field collecting data concerning intercompany sales of gasoline. These data are being supplemented by a careful examination of the accounts of certain representative refiners to ascertain the exact cost of refining different kinds of crude to produce gasoline, kerosene, lubricating oil and fuel oil.

"The schedules sent to refiners include questions on freight rates and marketing costs, and the rates are being checked by comparison with the tariffs filed with the Interstate Commerce Commission. Finally, a force of field men has collected hundreds of cases of actual retail gasoline prices from all sections of the country. Tank-wagon tickets and invoices show the prices paid by the garages to refiners and jobbers, thus affording a check on statement by the latter.

Data on Oils

"In order to be able to judge whether, as alleged, relatively low prices of other refined products have made it necessary to increase gasoline prices out of normal proportion to the rise in crude, data concerning production and prices of kerosene, lubricants and fuel oil are being gathered.

"The capitalization, earnings, dividends, and the price of the stocks during

(*Continued on page* 700)

N. A. C. C. to Work for Preparedness

Government Has Authorized Creation of a Special Department of Wide Scope

NEW YORK CITY, April 12—The National Automobile Chamber of Commerce is going to assist the United States Government in military preparedness and has authorized Alfred Reeves, its general manager, to create a special department for this work. Mr. Reeves has already started to lay plans for the collection of information on motor trucks owned by private citizens throughout the country. The work will largely consist in compiling information on the numbers of different trucks in different cities throughout the country, so that in case of emergencies these trucks can be called upon for Government use and dispatched to any particular point without loss of time.

Formal Opening April 17

This new work of the N. A. C. C. will be formally opened at a luncheon at the War College, April 17, when Mr. Reeves and representatives of the different railroads and other transportation interests will discuss the matter with War College officials under General McComb. The plan is to co-operate with the Government in co-ordinating all of the transportation interests in the country. It is not enough that a plan for speedy mobilization of motor trucks in the different States be agreed upon, but it is essential that motor truck transportation be co-ordinated with railroad and perhaps steamboat service, so that the last word in efficiency would be possible in case of emergency.

The work of interesting the N. A. C. C. in this preparedness program has been carried on by Howard Coffin, who is a member of the naval consulting board and is devoting a great deal of time to this work. Mr. Coffin has discussed the question of motor truck military transportation with the War College, and as soon as the N. A. C. C. authorized the creation of a department for this work, the War College accepted the plan and issued invitations for the luncheon.

S. A. E. to Co-operate

It is expected that the Society of Automobile Engineers will co-operate in this work insofar as engineering questions are concerned. The S. A. E. Council went on record some months ago as being in favor of co-operating with the Government on questions of preparedness. Its work will naturally go hand in hand with that of the N. A. C. C.

Besides compiling information on the number of motor trucks in different cities as well as their capacity, it is expected that the N. A. C. C. preparedness plan will include a country-wide organization plan for the possible mobilizing of these vehicles into different divisions subdivisions, etc., so that should emergency arise the entire plan will have been perfected and nothing will remain but the putting into service of the vehicles.

The plan further contemplates arranging these trucks in convoy order according to makes, so that in an exigency it will be possible to form a convoy in any section of the country of thirty or forty trucks of the same make. This method of convoy formation has proved most effective in Europe.

It is further planned to arrange with factories for supplies of spare parts. The actual shipping of these parts will not be carried out, but unquestionably an inventory of spare parts carried in different parts of the country will be included.

The plan further embraces the organization of factory repair crews in the different truck factories. These crews could be organized and ready for transportation at short notice to any State in the Union. The plans include the possibility of organization within the crews to increase their effectiveness.

Steel King Tractor Manufacturing Plans Well Under Way

SAGINAW, MICH., April 8—The new tractor company, which will make the Steel King tractor, is a reality. The fact that $145,000 of the proposed capital stock of $200,000, which was declared by officials to have been subscribed for, and the announcement that the former plant of the Argo Electric Vehicle Co. has been secured makes it sure that activities will start without much delay.

Herman F. Moeller, who has done much of the experimental work, stated that construction of the first tractor was started about four years ago, and that since then about 100 were built, of which half are being used by farmers now and the other half are in the hands of dealers. The tractor has been perfected in many ways, and is believed to be as near perfect as it can be made. It will be sold for $985. It was announced that a contract has been made with a manufacturer of motors in Joliet, Ill., for motors having a total value of more than $200,000.

Saginaw Co. Yale Eight Maker?

SAGINAW, MICH., April 5—It is likely that the new concern which will make the Yale Eight will be known as the Saginaw Motor Car Co. The capital stock is to be $250,000. The price of the car is to be $1,285. L. J. Lampke is the designer of the car.

Reo Completes Plant Additions

New Truck Plant, Engineering Bldg. Addition, Warehouse and Clubhouse

LANSING, MICH., April 10—The factory additions of the Reo Motor Car Co., this city, started in October, 1915, are rapidly nearing completion. These when finished will add between 10 and 11 acres of floorspace and will include an addition to the engineering building, a new plant for the Reo Motor Truck Co., a receiving warehouse, and a clubhouse for the employees.

The largest building is the new truck plant which is 239 by 316 by 762 ft., totaling 176,294 sq. ft., or 4.05 acres. This building has been finished and is of the modern type of factory construction with ideal conditions for the workmen.

The clubhouse when finished will be a two-story building, 74 by 196 ft., totaling 45,672 sq. ft. This building is rapidly nearing completion and occupies the plot of ground once used as a testing track. In the new clubhouse there will be a large assembly room, where different kinds of entertainment may be had. There will be bowling alleys, billiard rooms, gymnasium with swimming pool. A serve-self restaurant for the workmen and separate dining rooms for the executives are other features.

Women Have Privileges

For the women who work in the offices there are rest rooms. Equal privileges are given the women in access to the libraries and reading rooms. On certain days the gymnasium and swimming pool and other sections are set aside for the women exclusively.

The three-story receiving warehouse is practically completed. The first floor of this building will be used as a part of the receiving and shipping department, the second floor to be equipped with equipment for enameling such parts as the hood, radiator cover, fenders, mud splasher, etc. From the third floor of the new warehouse to the third floor of the present paint shop there is a bridge of steel construction which crosses one street and two railroad tracks. This is for the convenience of handling the finished bodies as well as the completed car.

On March 1 there were on hand for immediate shipment at the Reo factories orders for more than 4200 automobiles and trucks, representing more orders on hand than have ever been at any one time since the inception of the company. Owing to this increased business, requiring practically a 24-hr. working schedule, the Reo Truck company will delay moving into the new plant for a time.

Chase Orders Over $300,000

March Business Booked by Syracuse Concern Largest in Its History

SYRACUSE, N. Y., April 8—At a meeting of the board of directors of the Chase Motor Truck Company of Syracuse, N. Y., held on April 7, a report was submitted by General Sales Manager H. T. Boulden, showing that up to April 1 the Chase company had on its books, and unfilled, orders amounting to $301,414.04, represented by business for domestic shipment. The Chase factory schedule outlined up to and including June 1 was practically contracted for by March 1, and as a result "stock chasers" from the Chase factory are on the jump to take care of the increased schedule production provided for. "Much credit for the rapid strides made by the Chase Motor Truck Co. in the past year is accredited to the aggressive selling methods instituted by our general sales manager," said E. A. Kingsbury, secretary and treasurer of the company.

The March business booked by the Chase company was the largest single month's business in the ten years' history of the company.

Railroads Anxious to Apply $5 Demurrage to Car Shipments

DETROIT, MICH., April 10—The freight car shortage, though improved, is still far from what it should be. Though the automobile dealers have shown improvement in taking prompt delivery of car shipments, the railroads feel that there is still much to be done in the way of co-operation on their part. The situation has caused the railroads much trouble, who are desirous of applying a special demurrage rate of $5 per day on automobile shipments. However, assurances that steps would be taken to correct the difficulty within the trade, has for the time delayed any such action. The proposition for a special increased demurrage charge to force the unloading of cars is likely to be brought up again on account of the extensive delays.

It is difficult to get a correct idea of the number of automobile freight cars needed daily by the Detroit manufacturers. Some of the automobile makers have been so greatly hampered in securing cars and have had at times such an accumulation of finished cars, all ready to be shipped, that they do not care to let any facts come into print, believing that the general public might not understand the situation and be under the impression that the manufacturer had been short on materials or was handicapped in some other way. One railroad man said that if 1000 more freight cars were placed at the disposal of the local automobile manufacturers to-day, tomorrow or any day, now, that they are all in the midst of their heaviest production, that, within 30 min. after the announcement of 1000 available cars was made, not one would be left without a bidder.

Market Prices Steady

NEW YORK CITY, April 11—Prices on automobile materials last week were steady. Copper has gone up ¼ cent a pound to 28¾, while rubber is a little lower. Demand for copper continues active, with a steady booking of orders from domestic consumers. Offerings were light in crude rubber. Consumers manifested little interest in the market.

Spring has brought a larger demand for gasoline. Garagemen in this city report that during the last few weeks a large number of automobiles have been withdrawn from storage, but say that the average time of withdrawal has been later than usual. The demand for gasoline has increased proportionately, but is not as large per car as in other years. If the purchase is made in a section of the city where rent is low and where other overhead expenses are not large, a gallon of gasoline may be bought as low as 27 cents, and in the suburban districts of Long Island this price prevails.

Daily Market Reports for the Past Week
